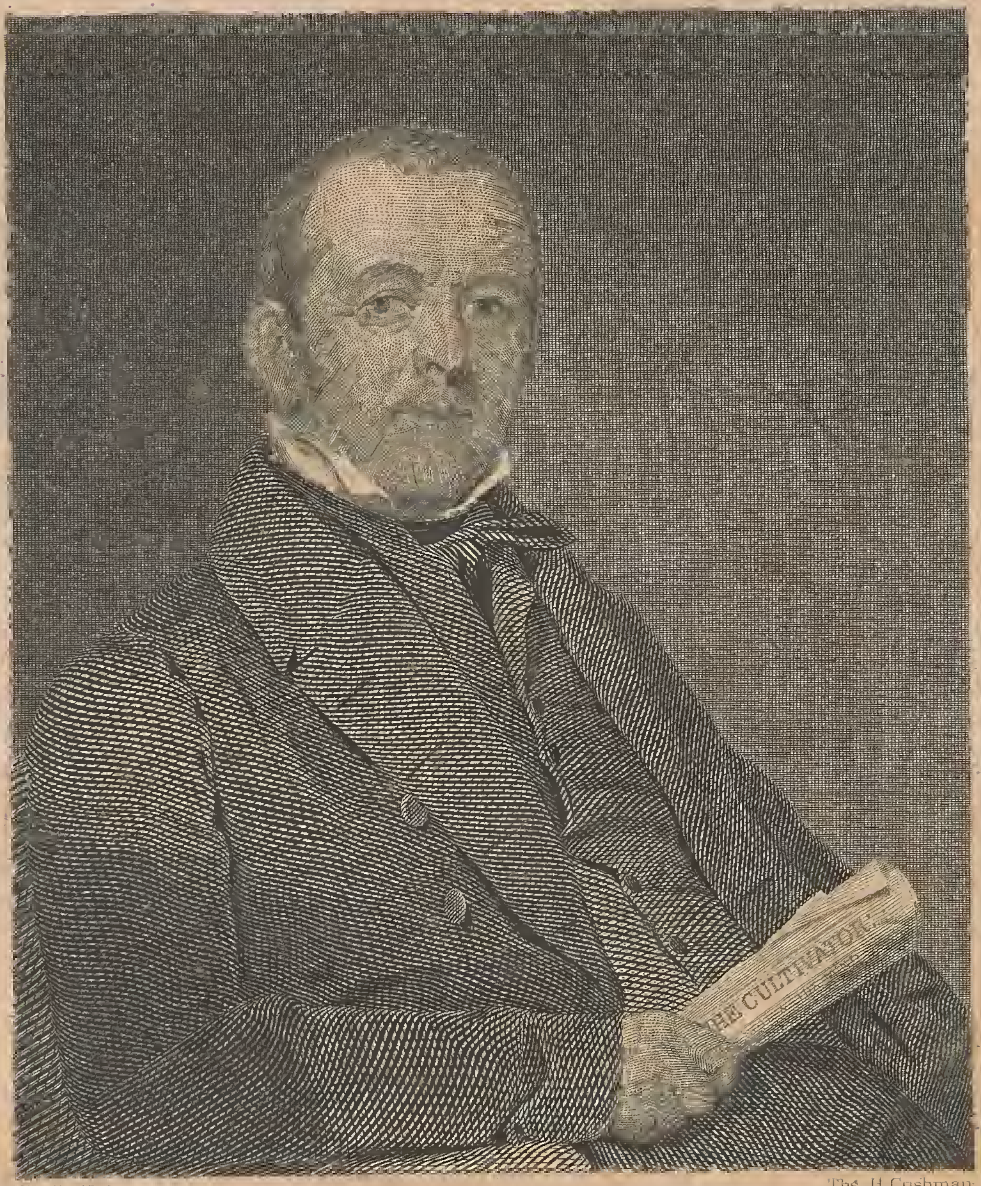
Demaree: "remarkable journal... ahead of its time"... the best agricultural periodical published in the East, if not the whole United States."



Fredk. Fink. Ths. H. Cushman.

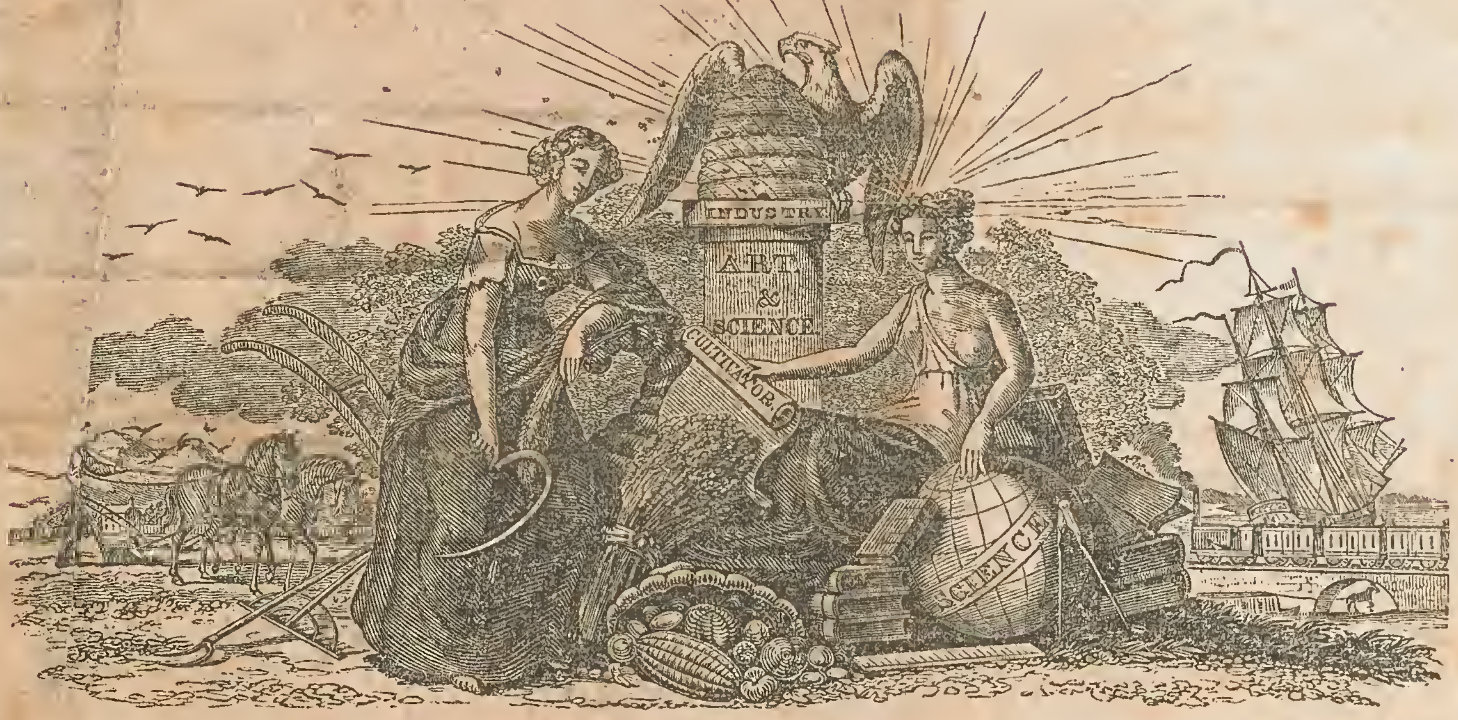
With affectionate regard
Jesse Buel

THE CULTIVATOR,

A MONTHLY PUBLICATION,

DESIGNED TO

IMPROVE THE SOIL AND THE MIND.



CONDUCTED BY J. BUEL, OF ALBANY.

VOLUME V.

SMITHSONIAN
JAN 09 1987
LIBRARIES

ALBANY, N. Y.
FROM THE STEAM PRESS OF PACKARD, VAN BENTHUYSEN & CO.
....
1838-9.

THE CULTIVATOR:

A MONTHLY PUBLICATION, DEVOTED TO AGRICULTURE.

I KNOW OF NO PURSUIT IN WHICH MORE REAL AND IMPORTANT SERVICES CAN BE RENDERED TO ANY COUNTRY, THAN BY IMPROVING ITS AGRICULTURE.—*Wash.*

VOL. V. NO. 3, WASHINGTON-ST. ALBANY, N. Y. MARCH, 1838. NO. 1.

Conducted by J. BUEL, of Albany.

TERMS.—ONE DOLLAR per annum, to be paid in advance. Subscriptions to commence with a volume.

Special Agents.—L. & R. HILL, Richmond, Va.; BELL & ENTWISLE, Alexandria, D. C.; GIDEON B. SMITH, Baltimore, Md.; JUDAH DOBSON, bookseller, and D. LANDREITH, seedsman, Philadelphia; ISRAEL POST, booksellers, 88 Bowery, ALEX. SMITH, seedsman, P. WAKEMAN, office of the American Institute, Broadway, N. York; E. M. HOVEY, Merchants's Row, Boston; ALEX. WALSH, Lansingburgh, gratuitous agent. For general list of agents see No. 12, vol. iv.

The Cultivator is subjected to common newspaper postage.

☞ Price of the published volumes, 50 cents per vol. stitched—the four volumes bound together, $2.75—bounded in two volumes, $3—the four vols. bound each separate, $3.25.

THE CULTIVATOR.

TO IMPROVE THE SOIL AND THE MIND.

Our Fifth Volume.

Agreeable to our proposition, we commence our fifth volume upon an enlarged sheet, and at an advanced price. To the individual subscriber the advance in price is trifling, while the aggregate will enable us greatly to improve the utility of our paper; and of our disposition to do this, we give a substantial evidence in the outset, in the number and expensiveness of the cuts, and in the entire sheet of extra matter, containing the very interesting proceedings of the State Agricultural Society, and State Agricultural Convention, recently held in this city. By this extra sheet we incur an individual expense, to the printer alone, of *five hundred and fifteen dollars.* And we beg gentlemen of intelligence and candor, after they have carefully perused the thirty-two pages which we give to-day, to put to themselves the question—"Am I not likely to derive a benefit, in the management of my farm the coming year, from the information contained in these two sheets alone, greater, far greater, than the paltry amount of a year's subscription to the Cultivator?" If, as we believe, the response will be in the affirmative, we hope they will be induced, from a spirit of philanthropy and patriotism, to endeavor to extend these benefits to their friends and neighbors, by enlarging the sphere of our circulation.

The better to enable us to carry out our views of public usefulness, we invite the co-operation of our old and of new correspondents, particularly of such as can furnish us any thing new and useful, in their practice, in any of the departments of husbandry. Next to the satisfaction arising from honorable endeavors to promote our individual interest, is that which results from a consciousness of doing good to our neighbors, and to society at large: And it is by publishing our improvements in the great business which employs most of our population, that we make ourselves truly useful. There is no monopoly in the business of agriculture; there should be none; there can be none. The best requital we can make for distinguished benefits, resulting from an enlightened system of practice, is to tender to others a participation in the benefits which our better practice confers. It abstracts nothing from our enjoyments,—it adds to them—while it often contributes much to the stock of human comfort and public virtue. Acts of beneficence, though they may sometimes provoke the sneers of envy, are sure to receive the applause of the liberal and enlightened.

Agricultural Movements.

If we are permitted to judge from the spirit of our agricultural journals, and from the oral evidence which we daily hear of a like spirit among the people, we should consider this as the commencement of a new and auspicious era in the history of American husbandry. A disposition is every where manifested to enlighten, improve, and elevate our agriculture, and our agriculturists. In most of the states, geological surveys have been made, or are in progress. In several states, bounties are awarded for the culture of the mulberry and the production of silk. Maine gives a liberal bounty on the culture of wheat, from her state treasury; and a bill is now before the legislature of Massachusetts to pay a like bounty. Massachusetts has also made provision for an agricultural survey of the state, and a very able gentleman, Rev. H. Colman, as already devoted a year to the labor. A proposi- n is before the legislature of Maryland to establish icultural schools. Kentucky is organizing a state rd of agriculture, or state society; while our ver sisters, Ohio, Indiana, Illinois, Michigan, and even one-year-old Wisconsin, from the spirit they are manifesting, seem determined not to be outdone in rural improvements, by the older states.

But let us come to New-York. The meetings of the State Society and State Convention are fraught with great public usefulness. The reports and other documents which we give to-day, abound in valuable information, and will be read with great interest. The subjects which they embrace are intimately interwoven with our prosperity. The matters to be reported upon at the next meetings are numerous and interesting; and from the character of the gentlemen to whom they are severally assigned—and the time allowed them to collect and mature their reports, we hazard little in saying, that they will furnish an invaluable fund of information in the practical business of our husbandry. There seemed to be in these meetings no shyness,—no diffidence—no doubt of the propriety of asking from the legislature, as matter both of expediency and right, an appropriation—a liberal appropriation—towards improving our soil, and the minds of those who are destined hereafter to cultivate it. Many of the members of the legislature partook in the deliberations of the convention, and accorded heartily in the measures which were there adopted.

A small matter set Right.

"The Conductor of the Cultivator has, however, gi-
"ven notice of his intention to enlarge that paper *to the*
"*size of this sheet.*"

The above is quoted from the first number of the Monthly Genesee Farmer for the current year. Whether intended to be so understood or not, it would seem to imply, that the Monthly Genesee Farmer and the Cultivator, in its enlarged form, contain a like quantity of matter. We asked our printer to make an estimate of the quantity of matter in each, and he has given us the following as the result:

This number of the Cultivator contains, by printer's computation,	120,610 ems.
The first number of the Monthly Genesee Farmer contains, by like computation,	101,556 ems.
Difference in favor of Cultivator,	19,054 ems.

This balance, multiplied by twelve, the numbers in a volume, gives as the difference in a volume of each, 192,640 ems, equivalent to thirty pages of the Monthly Genesee Farmer—in favor of the Cultivator; and if we add the extra sheet which accompanies this, and which contains as much as twenty-two pages of the Monthly Genesee Farmer, the difference in matter, in the two papers, will amount to 52 pages in favor of the Cultivator, to say nothing of our great expense for cuts. We make this statement merely to set the matter right, without the least wish to charge our cotemporary with a wanton error; for, until he saw our sheet, which he could not have seen when he made the comparison, he could not judge correctly of the matter which it does contain. We would only say, he is not good at *guessing*.

Cultivator Premiums.

We have reason to believe, that the premiums which we offered in the first number of our last volume, have been productive of highly beneficial effects, not only as regards tillage crops, and the management of the dairy, but in reference to the construction of barns and other out-buildings. If the plans which we have published, and publish to-day, are not the best, they are certainly much better than are usually followed, and by directing the public attention to this branch of improvement, the result cannot but prove beneficial. Influenced by these considerations, we are induced to offer the following premiums for the coming year.

For the best plan of a farm dwelling-house, of stone, brick or wood, to cost from six hundred to two thousand dollars, a premium of *twenty dollars.*

For the discovery and publication of an effectual means of preventing the ravages of the grain-worm, *fifty dollars.**

For the most profitable acre of Indian corn, *ten dollars.*

For the second most profitable crop of Indian corn *five dollars.*

For the most profitable acre of ruta baga, *ten dollars.*

For the second best do. *five dollars.*

The plans for a dwelling-house must be accompanied by drawings of the elevation and ground plan, and must comprise estimates of expense of wood and brick or stone. The premium on the mode of preventing the ravages of the grain-worm will be withheld until the remedy has been satisfactorily tested. We shall require, in the tillage crops, the same details of expense, product and profit, as are embraced in the statements published in our last number, and, where the competitor is a stranger, a like certificate of a magistrate as to his credibility. The large premiums will be paid in medals or plate, and those of five dollars in bound volumes of the Cultivator.

There is great room for improvement in the construction of our farm houses, both as regards economy and comfort. It is a subject well worthy the study of our architects; and if we can be a means of turning the public attention to the matter, the result cannot but be beneficial.

The New Husbandry.

We have been asked, and have promised, to explain, what we mean by the *New System of Husbandry:* and we now proceed to redeem our promise.

The system is *new* only comparatively, and in contradistinction to the *old* system, which is generally adopted in the first settlement of a country, in some degree as a matter of necessity; but which, being once established, is too often persisted in, with a reckless indifference to ulterior consequences, long after the necessity for it has ceased. This particularly happens in countries like ours, where new and virgin soils are continually inviting to emigration. What we denominate the new system, has long been in operation in the valley of the Po, in Italy,—indeed it seems to have been practiced there by the Romans, in the meridian of their greatness—and in Flanders,—and for the last half century in Great Britain; and it has, besides, for sometime, had many faithful followers in the United States. By the *old* system, we mean that which, generally speaking, has impoverished, and is still impoverishing, the soil on our Atlantic border, and which is already causing indications of premature exhaustion and poverty in some portions of the new west. "As much vacant land as this district contains" (says a late writer of East Virginia)—there is but little uncultivated [old fields] which, until enriched, will yield any clear profit. Therefore, Eastern Virginia, in its present state, is fully populated, and no increase can be expected, *except from the improvement of the soil, and the consequent increased means of subsistence.*" This remark will hold good in many portions of the older states. By *New Husbandry*, we mean the *art*,—and to many yet a *mystery*—of progressively increasing the fertility and products of our soils, and the intrinsic value of our farms—and of thereby providing the means of subsistence for our increasing population.

There are no universal rules for doing this. Much depends upon climate, soil, and upon the distance and demands of the market. The products of the soil, as well as the demands for them, vary generally with latitude. Grain, pulse, roots, and grass, are the natural products of higher latitudes; rice, cotton, and tobacco, constitute the staples of more temperate regions; while the productions of the torrid zone vary from both of those before referred to. Though there are no definite rules of practice, that will apply to all, yet there are essential requisites to success that have a general application. These are capital, industry and perseverance, and knowledge to apply them wisely with effect, under the varied circumstances of climate, soil and market. Great success cannot be expected in any laudable undertaking, without persevering industry; and in regard to knowledge, the laws which govern matter, upon which our labors are to be expended, are the same every where; and we are endowed with capacities for investigating, comprehending and applying many of them in aid of labor—the profits of which are in a measure graduated by the intelligence which governs and directs it.

The New System of Husbandry, or the art of increasing the fertility and products of the soil, consists in

1. Manuring.
2. Draining.

---

* Should the legislature offer a bounty for this discovery, this premium will be withdrawn, and the amount offered upon other objects. Should they not offer such bounty, we shall be glad to add to the fifty dollars such sums as other gentlemen may please to contribute, in order to make the amount more respectable.

3. Good Tillage.
4. Alternating Crops.
5. Root culture. And,
6. In substituting fallow crops for naked fallows.

Most of all these are necessary to good farming, according to soil, climate and location. They are the distinguishing traits of the new husbandry; and as they are practised with more or less fidelity and judgment, in that proportion are they likely to advance the condition of our agriculture, and to benefit the commonwealth.

These objects have become so hackneyed, from our repeated attempts to illustrate their bearing upon the prosperity of our country, that we almost despair of interesting our readers by what we have to offer; but as we labor in our vocation, and deem the matters in question of deep interest to the farmer, we shall again throw our seed abroad, trusting to the indulgence of our patrons, and in the hope, that, at least a portion of it may fall upon good ground, and yield a reasonable increase.

We intend to discuss the several subjects we have named, and shall endeavor to show the *why*, and the *how*, each of them tends to benefit the farmer, and to advance improvement in our husbandry. In the remarks we shall offer, it will be our endeavor rather to explain the principles upon which the new system is founded, and which have a common application, and to demonstrate their beneficial influence in husbandry generally, than to detail the minutæ of practice, which must, in some degree, ever be influenced and controlled by local causes.

I. MANURING.

The first requisite to improving the fertility of the soil, is plenty of food for the crop, which it is destined to nourish. The meal chest must be occasionally replenished, or it will not long serve to supply the wants of the family. The kine must have daily her forage, or her grain, or she will withhold her accustomed tribute of milk. The field which yields an annual contribution to the husbandman, will become sterile, if nothing is returned to replace the crops annually carried off. Philosophers have speculated for ages, as to *What constitutes the food of plants?* Without recapitulating the various theories which have had their day, upon this point, every farmer can readily respond to the question, from personal knowledge—that it is MANURE—vegetable and animal matters,—which constitute the true food of farm crops. Mineral, fossil and earthy substances, may meliorate the soil, and increase its capacities for the healthy development and maturity of plants—or may impart wholesome stimuli to the organs of plants themselves,—but vegetable and animal substances, after all, constitute mainly the elementary food of plants: Crops are always good, on well prepared grounds, when these, in a soluble state, are known to abound; and they are always defective, or prove a failure, when these are wanting. Farmers should hence regard manure as a part of their capital—as money—which requires but to be properly employed, to return them usurious interest. They should husband it as they would their cents, or shillings, which they mean to increase to dollars. They should economise every animal and vegetable substance on the farm, and when it has subserved other useful purposes, apply it, by mixing it properly with the soil, to the increase of the coming harvest—put it to interest, that it may return the owner its per centage of profit, in grain, roots and forage, and ultimately in the increase of meat, and in the products of the fleece and dairy. Every load of manure, well applied to the farm, will increase its products to the value of one dollar. The farmer, therefore, who wastes a load of manure, is as reckless and improvident, as he who throws away a bushel of corn, in these dear times. Not only what is denominated manure, as the contents of the cattle and hog yards, and the cleanings of the stable—the amount of which may be greatly increased, by stalks, weeds, vines, and other vegetable matters—may be transformed into farm produce—but the rich earth of swamps, ditches and waters, the leaves of the forest, urine, soap suds, &c., are all convertible to a like use. He that will not feed his crops with manure, should not complain if his crops fail to feed him with bread.

As the grain, roots and forage destined to feed the family, and the farm stock, require the best care of the husbandman, to prevent waste and injury, so does the manure which is destined to feed his crops. Fermentation, if suffered to exhaust its powers upon it, materially lessens its value; the wind and the sun dissipate its virtues, and rains leach it, and waste its fertilizing powers. The same care given to the food of vegetables which should be given to the food of animals, will be richly recompensed in the increased product of the harvest.

Lime, marl, gypsum and ashes, are all beneficially applied to increase fertility, under certain circumstances, which it is unnecessary for us here to particularize. Stiff clays are also benefitted, by the application of sand; light sands are improved by the admixture of clay; while both clay and sand are improved by the addition of marl, or other calcareous substances.

If we contrast the common with the improved practice, in regard to the management of dung, we shall readily see, that the difference, in preserving the fertility of the soil, is incalculably great—enough to induce poverty in one case, and to enrich the proprietor in the other. Even the best class of our farmers, who are deemed judicious managers, seldom avail themselves of half the resources of fertility which their farms or neighborhoods afford—not half that are put in successful requisition by the farmers of Great Britain and Flanders. Besides, what manure they do make is in general badly husbanded. They suffer the gaseous portions to waste in the air, instead of being absorbed by, and enriching the soil; and the liquid to course down hill to the highway or the brook. But what shall we say of the mass of our farmers?—We have travelled hundreds of miles to the west, and seen great quantities of manure, in the yards and about the barns, often the accumulation of years, seemingly considered by the owners rather as an incumbrance, or a nuisance, than as a source of fertility and of wealth. In the new system of husbandry, the farmer's profits are in a measure graduated by the quantity of manure he is enabled to produce from his farm. In the first number of our fourth volume, we gave estimates, from high authorities, of the amount produced upon farms in Great Britain. Dr. Coventry, Agricultural Professor in the Edinburgh University, gives four tons of manure to each acre of straw manufactured by farm stock. A Berwickshire farmer, quoted by Sir John Sinclair, obtained four cart loads, of 30 to 35 cubic feet each, from every ox wintered upon straw and turnips. Meadow land is stated to produce from four to six tons of manure to the acre, and the available sources of fertility upon a farm are estimated to be sufficient to give a full supply of manure once in every course of the four year system of husbandry. Arthur Young, with six horses, four cows, nine hogs, and suitable litter, made 118 loads of dung, 36 bushels each, in a winter. Cattle fed with turnips are computed to make double the manure that those do which are fed on dry fodder alone; and an acre of turnips, with an adequate quantity of straw, has produced sixteen cart loads of dung. It will be readily perceived, that by this mode of management, ample means are provided for keeping up the fertility of the soil, when put under a four shift system of husbandry.

What now is the common quantity of manure under the old system? Taking our state, or our country at large, we are confident the average quantity which is judiciously applied, will not amount to one load an acre, and we are doubtful if it will amount to half a load. Can it be wondered, then, that under such reckless management, of returning to the soil only a quarter, or an eighth, of what we take from it, of the food of plants, that our lands should continue to grow poor, till they no longer yield a reward to culture?—The cultivated lands in this state are estimated at eight millions of acres. On the supposition that one half of them is appropriated to tillage and meadow—and this is a low estimate—we might produce and apply annually, under the new system of husbandry—and we ought to do so—sixteen millions tons of manure, worth to the country, at a low computation, sixteen millions of dollars;—whereas, we now produce, under the old system, certainly not more than four millions of tons—thereby suffering an annual loss, independent of the certain and constant diminution in the product and value of our lands, of twelve millions of dollars in the single item of manures! This is not a visionary speculation—it is sober truth—and we ask any intelligent man, to show, from facts, a less unfavorable conclusion.

We will merely remark here, in regard to the application of manures, that if used in an unfermented state, they should be buried with the plough, and applied to a hoed or autumn-ripening crop; if used in a rotted state, they may be blended with the surface, and applied to a summer-ripening crop. We will give our reasons for this practice. Manure fertilizes in two ways—by the gaseous matters which are evolved in fermentation, and which *rise;* and by liquid matters, which *sink*. If used before it has parted with its gases, manure should be buried, that the incumbent soil may imbibe these fertilizing elements. If the manure has been rotted, it has parted with its gaseous matters, and all its remaining fertilizing properties are liable to be carried down by the rains—hence this may be deposited near the surface. Again, fresh manures, even in a liquid form,[*] induce a rank growth of *herbage;* but they do not produce good plump *seed.* Hence if applied to common small grains, they cause a great growth of *straw* at the expense of the *grain:* Fermentation being most rapid at midsummer, when the seed, and not the straw, requires the food. But the autumn-ripening crops, as corn, &c., are in that state, at midsummer, which requires strong food to perfect their stalks and leaves; and the fermentation of the manure has subsided before the *grain* matures in autumn. Fossil manures, as lime, marl, gypsum, are applied upon the surface, or buried superficially, because their disposition is to settle down, and they give off no gaseous food.

Individuals, it is true, are but units—yet the aggregation of units make millions, and the aggregation of individuals constitutes nations. We should all act as though individual example had an imposing influence upon the whole. In the matter which we have just discussed, every farmer may be assured, that by adopting our suggestions, he will unquestionably promote his own interest, and by his example, benefit society.

Analysis of Wheat.

Wheat is composed almost wholly of starch and gluten. It is the latter which gives grain a pre-eminent value, it approximating most to animal matter. Yet starch imparts to flour its greatest excellence in market. Summer wheat contains more gluten, ordinarily, than winter wheat. The wheat of cold latitudes contains more starch, and that of southern latitudes more gluten. The summer wheat of Italy is chiefly employed, at Naples, for macaroni, on account of the gluten with which it abounds, and which renders its paste peculiarly adhesive. Wheat ordinarily contains from eighteen to twenty per cent of gluten, according to Davy; while, according to Chaptal, rye affords but one per cent, barley from five to eight, and oats one to two. The more gluten there is in flour, the more readily it ferments, or rises in the dough trough; and if the gluten is destroyed, the dough turns sour by fermentation. Hence the nutrient quality of wheat is in some measure determined by the gluten it contains.

A friend having submitted several kinds of wheat to rather an imperfect analysis, with a view to determine the quantity of gluten in each, has given us the following as the result. All the specimens were submitted to a like process; and although the result may not indicate the *whole* of the gluten in either, the relative proportions are presumed to be accurate. Twelve grains of each were submitted to experiment.

Kinds of wheat.	*Weight.*		*Gluten.*	
Italian, from Utica, ...	9	grains.	1½	grain
Siberian, ...	9	"	1½	"
Tea, from Vermont, ...	8½	"	1	"
Common Spring Wheat, ...	8½	"	¾	"
Early May, from Virginia, ...	7	"	¼	"
Red River, from Galena, ...	8	"	⅛	"
Egyptian, from Vermont, ...	10½	"	½	"
Giant, from England, ...	10	"	none.	

The only inference we would venture to draw from this analysis, is, that the Italian and Siberian wheat seem to be identical—and that even the tea wheat may be the same, differing in the quantity of its gluten only from the circumstance of its being grown in a higher latitude, so far as this test can be relied on.

Things which we Want.

We want, imprimis, stronger inducements to agricultural labor, through our public authorities, by means of a liberal policy of patronage, in bounties and rewards; and we want a stronger guarantee for recompense, in the establishment of a better system of practice.

We want more *public,* and less *party* spirit—more devotedness to the *state,* and the interests of the people at large, and less to local interests, individual cupidity, and personal aggrandizement.

We want more stimulus to individual effort, and less to joint stock companies. Men will be guilty of acts of injustice and oppression, in a corporate capacity, which they will be ashamed to commit on their individual responsibility. In the one case they do but *share,* and they generally contrive to shift on to others, the odium of a bad act. But alone, they have no subterfuge, no excuse.

We want, for our boys, who are destined to till the earth, scientific and industrial schools, that they may acquire, simultaneously, and in the scholastic period of life, a knowledge of the best practices in farming, and of the principles upon which it can now alone be judiciously and successfully conducted.

We want, in due time, an *agricultural* survey of the state, which shall collect and make known to all, the best practices in farming which prevail in each district—as also the labor-saving implements employed in each, and their relative usefulness, the breeds of domestic animals, products and profits of crops, new subjects of culture, &c.

We want more *practical* business men in our legislative halls as well as upon our farms—men of sound judgment and independent bearing—and who, though they do not *talk* as much, can *think* and *act* as correctly and as promptly, as *professional* talkers; and who, knowing best the true interests of the mass of our population, are likely to do the least injury, if they do not do the most good.

---

[*] Col. Le Courteur—(see Farmers' Magazine)—tried stable manure, and liquid manure, the latter diluted, upon his wheat. The grain tillered much, or gave a great growth of straw and grass; but the product in grain was diminished. When the liquid manure was applied a second time, by being poured upon the growing wheat, the straw was very rank; the plants produced only a few ears of wheat, and those were very defective in grain.

We want a more extended circulation of agricultural periodicals—because they disseminate useful knowledge, stimulate industry, call into action latent genius, awaken laudable competition, induce general improvement, bring into exercise the noblest feelings of our nature, and inculcate good will to our fellowman.

We want to have inculcated and taught, by precept and example, in our public halls, in our social circles, and in our schools, high and low, the great moral and political duty, of identifying our individual with the public interest, and of considering the one as in a great measure inseparable from the other.

ON OUR FARMS,

We want more system—more employment for our females, that they may be more healthy, more robust, and more serviceable to posterity—more contentment with our rural employments—a greater desire to increase our knowledge, to improve our practice, and to bring our sons up "in the way they should go"—as independent tillers of the soil.

We want more attention paid to augment our manures, the food of our farm crops, that our lands, instead of growing poorer every year, may increase in fertility, in products and in profits.

We want to understand, better than we do, the principles and the practice of draining, that much of our best land, now unproductive and noisome, may be rendered productive, profitable and healthy.

We want to extend the culture of roots and clover, as tending to perpetuate fertility, fatten cattle, furnish manure, and fill the granary.

We want the conviction that we *can* improve, the determination that we *will* improve, and we shall then soon become conscious that we *have* improved, in the management of our farms.

On the Improvement of Grass Lands.

Although the alternation of grass and grain crops is deemed most profitable, on soils and in situations which will admit of this kind of husbandry, yet there are many situations in which this alternate change cannot be carried into effect without manifest prejudice to the interests of the cultivator. There are some soils so natural to grass, as to yield an undiminished product for many years, almost without care or expense. There are others upon the banks of streams which frequently overflow, which it is prudent to keep in grass, lest the soil should be worn away by the rapid flood of the waters. Others again are too precipitous, or too stony, to admit of arable culture. Nor should we conceal the fact, that it is still a controverted point, whether rich stiff clays are not most profitable, when permanently appropriated to grass. Whatever causes prevail, the fact is indisputable, that a considerable portion of our lands are and will continue to remain in meadow and pasture. It is with the view to aid the farmer in correcting any defects that may exist in such grass grounds, and in improving and keeping them in condition, that we offer the following suggestions. And first,

OF PASTURE.

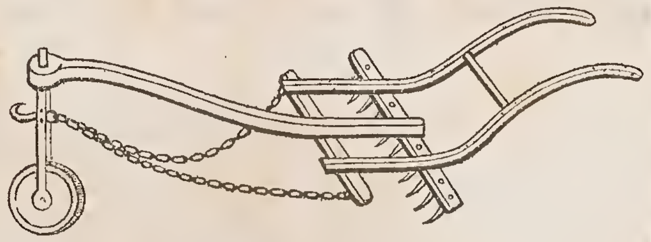
The evils that are experienced in pasture grounds, are, the gradual disappearance of the best grasses; the growth of mosses and weeds in their stead; and the prevalence of coarse herbage in situations where there exists a superabundance of moisture. Wherever there are stagnant waters, as upon flat surfaces, the pasture is rendered peculiarly unhealthy for sheep; but it is remarked, that if the water is in continued motion, as is generally the case upon the declivities of hills and mountains, no ill consequences follow.

To remedy the evils we have enumerated, and to improve the condition of pasture grounds, one or more of the following expedients may be advantageously resorted to, viz. sowing and harrowing in grass seeds, scarifying, bushing, draining, manuring, top-dressing with marl or lime.

Grass seeds may be sown either in the autumn or spring, followed by the harrow, and if practicable by the roller. The harrow partially extirpates the mosses, breaks and pulverizes the surface, and buries the seeds; and the roller presses the earth to the seeds, and smooths the surface. The bush harrow is to be preferred. This may be constructed by interweaving some strong, but pliant branches of trees, through the open squares of a heavy harrow, which thus forms an efficient brush, and when drawn over the ground performs its duty perfectly during a short distance; but the branches being pressed close, and worn by the motion, soon become so flat as not to have the effect of spreading the earth, thrown upon the surface by earth-worms or ground-mice or ants. It is therefore recommended in British Husbandry, as a better mode, to fix the branches upright in a frame, placed in the front part of the carriage of the roller; by which means they can be so placed as to sweep the ground effectually, and when worn can be moved a little lower down, so as to continue the work with regularity. This operation also completely breaks and scatters the manure dropped on the field by the stock, and partially incorporates it with the surface mould.

Scarifying is cutting the sod and loosening the surface. Concklin's Press Harrow is a suitable implement for this purpose. We also subjoin the drawing of an implement constructed for this purpose, which we take from British Husbandry, calculated to be drawn by a one or two horse team. [See fig. 1.]

[Fig. No. 1.]



This implement is intended to cut the sod perpendicular, so far down as to sever the roots of the grass, which occasions it to throw out fresh roots. It slices the sod, without tearing it, and should be constructed with a number of very sharp coulters, fixed into a cross beam at such distances as may be thought advisable, from six inches to a foot, and of a width according to the strength intended to be employed in drawing it. The blades should be occasionally whetted to preserve their edge, and the implement should be used when the ground is in a moderate state of moisture, and the grass short. If the land is poor or moss bound, it may be passed crosswise. It is best adapted to moist clays, which do not contain stones or gravel. It is advantageously used to precede the sowing of grass seeds. The foot wheel is to regulate the depth of the work.

Draining improves the quality of the herbage, and marling or liming increases the quantity. It is remarked, that animal dung, when dropped on coarse pastures, produces little or no benefit, but when calcareous matters have been laid upon the surface, the finer grasses soon take possession of it.

Manures are seldom applied to pasture, especially with us; but applied in the form of compost, as a top-dressing, they are serviceable. Gypsum and spent ashes may be applied with undoubted benefit in most cases.

It need hardly be added, that bushes, thistles and other perennial weeds obstruct the growth of grass, and that they ought to be carefully extirpated.

Our pasture grounds are generally left to take care of themselves; but there is no doubt but some expense bestowed upon their improvement, in some of the modes above suggested, would be profitably laid out.

OF MEADOW.

The crop being here annually carried off, it becomes a matter of necessity, if the field is to be kept permanently in grass, to apply manure occasionally, if we would prevent a diminution of product. It is affirmed, that a perfectly thick bottom cannot be maintained on permanent meadows, in England, unless it is manured every second year. Gypsum will effect much here, upon dry soils, though there its effects are equivocal; but gypsum alone will not suffice here. The average product upon our old grass lands will hardly average over a ton and a half an acre. With a biennial or triennial top-dressing of dung or compost, where the sod is in good condition, it is believed the average would be double.

Meadows are subject to all the evils that are experienced in pastures, from mosses, wetness, and the diminution of the finer grasses, besides the greater exhaustion of fertility consequent upon carrying off the annual growth; and the same measures are best adapted to renovate them. Meadows are generally depastured after the hay has been taken off, and the rowen partially grown. "After the cattle have been removed," says an English writer, "the land is *bush harrowed and rolled*." It has been stated, though some question the fairness of the experiment, that the operation of heavy rolling has been found to add six or seven hundred weight of hay per acre to the produce of the crop.*

The effect of pasturing meadows in the spring, upon the coming grass crop, has been a matter upon which farmers have differed—though all agree that heavy cattle should not be kept on so late in autumn, or put on so early in spring, as to injure the sole of the sod, by poaching it when in a wet state. Mr. Sinclair has stated, that a given space of the same quality of grass having been cut towards the end of March, and another space of equal size left uncut unthe last week in April, the produce of each having afterwards been taken at three different cuttings, that of the space last cut exceeded the former in the proportion of three to two; and in one instance during a dry summer, the last cropped space exceeded the other as nearly two to one.* It is generally conceded, that it is better to feed off rowen, than to cut it as a second crop.

Preserve your best Animals for Breeding.

The complaint is general, at least throughout the eastern states, that the stock of neat cattle has been greatly diminished within a few years, and that prices have consequently advanced to an unprecedented pitch. And it is believed to be a general fault among farmers, that they sell their best young animals to the butchers. The season has arrived when it becomes the farmer to improve his practice in these matters. He should preserve his best animals for breeding; raise more stock, if his farm will permit, and substitute improved breeds, or at all events cross upon them.

He should preserve his best individuals for breeding. For a dollar or two extra the farmer sells his best calf to the butcher; which, if kept as a breeder, would not only serve to improve his whole stock, but the individual thus sacrificed for a dollar or two, would in many cases, be worth, at the working or milking age, and with no extra expense of keep, ten, twenty, or fifty dollars more, than the poor calf rejected by the butcher, and which consequently serves as a breeder upon the farm, still further to depreciate the character of the farm stock. The farmer who breeds from poor or inferior animals, in a manner throws away capital. He who breeds only from select animals gets common interest. And he who breeds from select animals, of the choice breeds, gets compound interest. Choice working oxen, of four or five years old, of common stock, or with the Devon cross, have recently been sold for one hundred to one hundred and fifty dollars the pair. This surely affords a handsome remuneration to the breeder. There is generally a difference of about one-half, in cows and oxen, between select and inferior individuals of the common breeds.

He should raise more stock.—Many of our farmers have been "penny wise and pound foolish," in destroying calves at their birth, in order to turn a few gallons of milk into ready money, thus retarding the increase, and enhancing the value of dairy stock. Cattle are the source of fertility to the farm—dung makes fat crops, and fat crops make fat cattle. In districts remote from market, where land is cheap, the rearing of neat cattle should certainly be a profitable business. It is so upon well managed farms, in the contiguity of markets, where lands are high. It may be made still more so at remote points, where lands are comparatively low, particularly if select breeds, or select individuals, are employed as breeders. But,

He should select the breeds best adapted to his farm; and we refer to the report upon neat cattle in our extra sheet, for advice, as to the breed which *is* best adapted to his farm. Having determined upon this, let him stick to it; preserve his finest animals to propagate from; make it his business to improve, and he will soon find, that instead of ten and twelve dollars, his yearlings and two year olds will bring him twenty, fifty, and even a hundred and fifty dollars each—nay, the last summer has demonstrated, that choice animals, of improved breeds, will bring 1,500 to 2,100 dollars sometimes.

Our Agricultural Journals, continue to increase and to improve. The Genesee Farmer has been enlarged; and it has been announced that Willis Gaylord and John J. Thomas, both gentlemen of high standing as agricultural writers, are to assist in the editorial department. The Rev. Mr. Colman, very favorably known as an agricultural writer, and a practical farmer, has promised to lend all the aid to the New-England Farmer that his official duties will permit. In the mean time it will be seen, by this and our previous numbers, that several new agricultural journals have been started in the west. However individuals are likely to be affected by these arrangements, it is certain that the public will be greatly benefitted. We estimate, that every additional subscription to these journals, increases the annual products of the soil at least ten dollars; so that five hundred thousand new patrons would add five millions to our annual agricultural products. May these journals all deserve success, and all receive it.

Daubenton on Sheep.—We ask of the sheep farmer a careful perusal of this article, inserted under extracts—of the *whole* article. In this latitude, the loss in this useful animal, in winter, is often very great. If we mistake not, this article satisfactorily explains a prominent cause of the mortality, and suggests a preventive, which is, or easily may be, accessible to every keeper of a flock. The change which takes place in the quality of the food, when sheep are changed rom grass to hay, or where, from the ground being covered with snow, sheep are deprived of access to the turf, it is here pretty conclusively shown, must become a primary cause of disease, though the disease itself may not assume a formidable appearance for some time afterwards. The preventive suggested, is to give the animals, once a day, and particularly at the time of change in regimen, roots or other succulent food. So far as we have been advised, but very few sheep have died in flocks which have had a daily supply of ruta baga, or other roots. Half a peck a day, or seven pounds and a half, would constitute an abundant ration. Estimating the average product of ruta baga at 600 bushels, two acres of these roots would suffice to feed one hundred sheep about one hundred days, or during the winter months, and would in a great measure supersede the use of hay. But as the ground is not ordinarily covered with snow more than six weeks or two months, half the quantity would very much contribute to their health and thrift. The observations of Mr. Daubenton apply, with perhaps no less force, to the ox and other ruminating animals, and suggest the value of green food, during the unrelenting severities of a northern winter. As a substitute for turnips and other roots, we have no doubt that well cured corn stalks, cut and steamed, and given once a day, would answer a valuable purpose in counteracting the tendency in sheep to sickness, on a change from green to dry food. Browse, particularly the branches of resinous trees, as hemlock, spruce, pine, &c. it will be seen from the examination which is given to the subject, are also likely to prove highly beneficial; and even clay, by correcting the humors of the stomach, has undoubtedly been serviceable.

---

* Derbyshire Report; vol. ii, p. 88.

† Woburn Grasses, p. 389.

Horticulture.—While agriculture supplies our absolute wants, horticulture, her sister, furnishes us with many of the innocent luxuries and delicacies of the table,—with a succession of choice fruits and vegetables, grateful to the palate, and promotive of health,—and, as coming within the products of the garden, with a succession of fragrant and beautiful flowers, eminently calculated to add to our intellectual enjoyments. The inhabitants of large towns must be dependent, in a great measure, for these rural luxuries, upon the market gardners of their neighborhood; and the quantity and quality of the supply, and even the price, will materially depend upon the encouragement which is given to the producers—and upon the competition which is induced among them. Nothing tends more to bring into market choice fruits and vegetables, at an early season and in quantities, than the emulation produced among the growers by pecuniary rewards; and where this practice has obtained, the most beneficial results have been experienced. The cities of Philadelphia and Boston have shared largely in these benefits, in consequence of the premiums which have been annually awarded by their horticultural societies. The Philadelphia society awards annually from three to four hundred dollars to gardners and florists, for articles exhibited at their monthly exhibitions; and the consequence is, a constant improvement in the quality of the garden productions, and an increase in their quantity, which go directly and materially to benefit the consumers. We saw at the Philadelphia monthly show on the 16th May, a great display of fruit, flowers and vegetables; among the latter, quantities of new potatoes, cucumbers, cauliflowers, lettuces, &c. We have referred to this subject with the view of impressing upon the citizens of towns, who depend upon the market for the productions of the garden, the patronizing horticultural societies, as the surest means of being better and more cheaply supplied.

Mixed Crop of Corn and Potatoes.—John Lorrain planted ten acres of Indian corn, in rows eight feet three inches distant, and hills with three plants at eighteen inches in the rows. Between each row he planted two rows of potatoes. The product was 430¾ bushels of corn, and 848 of potatoes, or 43 of corn and 84 of potatoes on each acre. At another time he obtained 50 bushels of shelled corn, and 150 bushels of potatoes from an acre. A gentleman has just assured us, that he made a similar experiment last summer, alternating two rows of corn, at two and a half feet, and two rows of potatoes, with very great success. This mode of culture gives to the corn the advantages of air and sun, which it requires, while the shade of the corn does not prejudice, or but partially, the growth of the potato crop.

Value of Ruta Baga.

Our neighbor Bement has kept twenty of his Berkshire hogs, mostly full grown breeders, from the first of November to the 15th of February, upon ruta baga and buckwheat bran, at the rate of six bushels of roots and one of bran per diem, fed them two raw meals a day, and one warm meal, boiled. When he began to feed with the roots, the hogs were low in flesh; at the termination of the three and a half months, they were too thrifty for breeding, and some of them fit for the butcher. He estimates that four quarts of corn to each hog per day, for the time they have been fed with the roots, would not have brought them into a better condition than they now are. What then has been to him the value of his ruta baga?

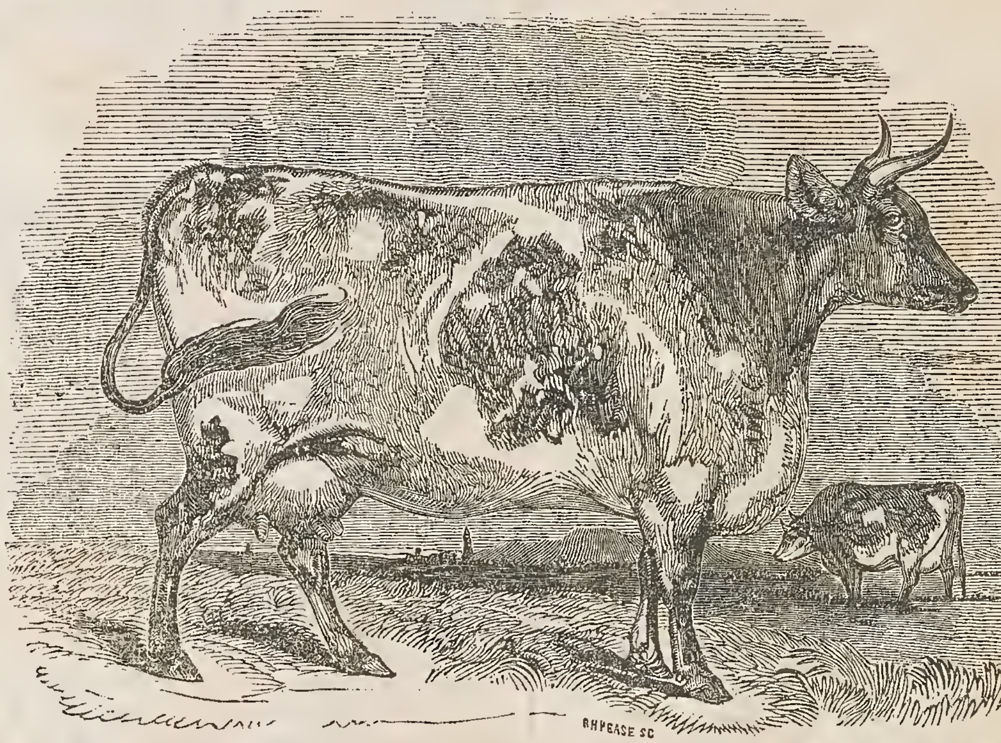
Four quarts of corn per day to each hog, would have amounted, in the 105 days, to 262 bushels, which, at 75 cents per bushel would be, ...	$196 50
Add 105 bushels buckwheat bran, at 15 cts.	17 50
And it shows that the ruta baga was worth the balance, to wit, ...	$179 00

Which, divided by 630, the number of bushels fed out, gives the value of a bushel, used in this way, at about 28½ cents. Deduct for the cost of raising, the quantity being about the average product of an acre, four cents the bushel, and it shows a nett profit of 24½ cents per bushel, or of $154.25 per acre. We call this a demonstration of the profits of root culture.

Select Breeds of Cattle.

We gave in our last volume, figures of the Improved Short Horns, of the Devons and Ayershire cattle, a bull and cow of each. We now present two other cuts, one (fig. 2,) the Yorkshire cow, and the other (fig. 3,) the Devonshire ox, which are correctly copied from the most approved British works.

[Fig. No. 2.]



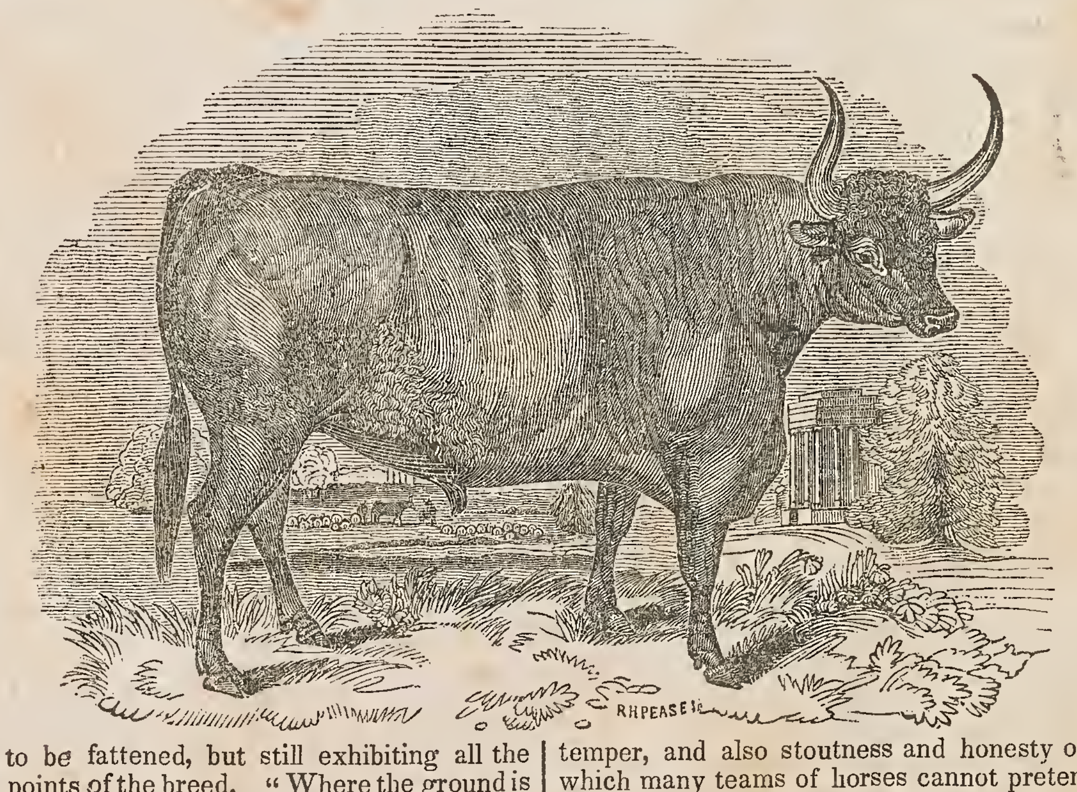
This, says the author of British Cattle, is a fair specimen of one of these cows, the character of the Holderness and Durham beautifully mingling. These constitute almost exclusively the stock of the London milkmen, and the numbers there kept to supply the metropolis with milk, amount to about nine thousand. They are celebrated alike for their milking and fattening properties. They are kept in houses, fed upon hay, turnips and brewers' grains, and milked without being suffered to go to the bull, till they no longer yield a profit on their keep, when they are dried off, and in a few weeks turned into good beef. They are said to give in some cases thirty, and even thirty-six quarts of milk per day. Loudon states the average product for the entire year at nine quarts per day—British Husbandry the average quantity given by each cow (probably when they are flush in milk only,) at twenty-two to twenty-four quarts. The good points of these cows are said to be well expressed in the following doggrel lines, from the Farmer's Magazine:—

> " She's long in her face, she's fair in her horn,
> She'll quickly get fat without cake or corn,
> She's clean in her jaws, and full in her chine,
> She's heavy in flank, and wide in her loin.
> She's broad in her ribs, and long in her rump,
> A straight and flat back, without ever a hump,
> She's wide in her hips, and calm in her eyes,
> She's fine in her shoulders, and thin in her thighs.
> She's light in the neck, and small in her tail,
> She's wide in the breast, and good at the pail,
> She's fine in her bone, and silky of skin,—
> She's a grazer's without, and a butcher's within."

Several of the Yorkshire cows have been imported into our country, on board the London and Liverpool packets, to supply milk on the voyage, though not under their proper distinctive name—having been generally classed with the Improved Short Horns. One has been upon the farm of the Messrs. Townsends, which adjoins ours on the west, and another is owned by Mr. Bloodgood, whose farm adjoins us on the east. The latter, in February last, two weeks after she had dropped her calf, gave, upon moderate feed, thirty-three quarts and a pint of milk per diem. It is desirable that this valuable breed of milkers should be better identified, and their purity preserved among us, particularly in the great dairy district embraced between lat. 40° and 45°.

We have already given a general description of the Devon cattle, and the criteria of fine animals, vol i, p. 26, 40. The figure (3) here presented is that of an ox begun to be fattened, but still exhibiting all the prominent points of the breed. " Where the ground is not heavy, the Devonshire oxen are unrivalled at the plough. They have a quickness of action which no other breed can equal, and which very few horses exceed. They have also a degree of docility and goodness of temper, and also stoutness and honesty of work, to which many teams of horses cannot pretend."—*British Husbandry.* The greatest objection to Devon oxen is, that they are not stout enough for ploughing in heavy clay; and for this reason the Hereford cattle, which are a cross of the Devon upon a larger ani-

[Fig. No. 3.]



mal, are often preferred. We consider the Devon as admirably fitted to cross, for working cattle, with some of our native breeds. The Devons were introduced into Berkshire county some dozen years ago by Col. Dwight; and at the last fair in that county we thought the working cattle surpassed any we had before seen, and we attributed their excellence in a great measure to the Devon blood which we saw strongly developed in some of the finest individuals. We unhesitatingly recommend a cross of the Devons upon our native cattle, as a certain means of improving both their working and fattening properties.

Beet Sugar.

We have received several inquiries for information in regard to the manufacture of beet sugar, particularly the household manufacture. The sugar beet has been raised in various parts of our country, but we do not learn that any advances have been made in the manufacture of beet sugar. It seems to be well settled, that the manufacture is carried on more economically and profitably in large establishments, where steam power is employed, than it can be in small, and particularly in household establishments. The best directions we have seen for the latter, are contained in the report made to the French Royal Society, translated by Dr. Spoor, and published in the last volume of the Cultivator.

In general terms, the manufacture of beet sugar may be managed like the manufacture of maple sugar, after the roots are rasped and the juice expressed. The juice is to be boiled down, the syrup clarified, or defecated, and the process finished in the same manner that should be practised with the sap of the maple. The principal difference in the two operations is, that better materials are used, and more care employed, in clarifying the beet, than is ordinarily used in the maple process. Animal charcoal may be obtained in any family, by charring common bones in an iron covered vessel, say a bake pan. Cream of lime is but another name for whitewash. These are the chief materials used in purifying the beet, which are not used in the process of clarifying maple sugar.

It will be seen by a letter from A. Dey, Esq. in the extra which accompanies this, that a new process of manufacturing beet sugar has been patented in Great Britain, which promises important advantages. We are at the same time notified, through the National Gazette, that an important discovery has recently been made in the Duchy of Baden, for the desiccation, or drying the beet root, without impairing its saccharine qualities, by which means the manufacturing process may be continued throughout the year. The saccharine matter is besides in a double state of concentration. One hundred pounds of the root (we presume in its undried state,) are said to give, under the new process, ten pounds of sugar. The process has been examined by two commissions, one of Bavaria, and the other of Wurtemburgh. After six weeks labor in the manufacture, the two bodies declared as certain the advantages announced. Several companies have been formed on the continent to profit by the improvement. Our late agricultural convention have charged a competent committee to investigate and report upon the subject of beet sugar, at their next meeting; and from the character of the gentlemen named on the committee, we anticipate an able and valuable report.

While on the subject, we will repeat, what does not appear to be generally understood, that *large roots do not yield near so much sugar, in proportion to weight, as roots that are of medium or diminutive size.* And further, a fact that we have seen demonstrated by three years' experience, after the beet has attained to maturity, which is known by the tops ceasing to grow, and the under leaves becoming shrivelled and yellow, *the roots deteriorate—the sugar is changed to potash—according to the time they are left in the ground after the plant has ceased to grow.* These remarks apply equally to the sugar beet, common beet and mangold wurtzel—whether raised for the table, for sugar, or for farm stock.

Egyptian Wheat.

This was spoken of, with the other varieties of spring wheat, in our September number, volume iv. Since that time our attention has been particularly turned to this grain, by the receipt of several parcels kindly sent us, and by repeated inquiries where the seed could be purchased, and at what price. It has also been highly commended in the news journals.

This wheat is known under the various names of *Egyptian*, *Syrian*, *Smyrna*, *many spiked*, *reed*, and *wild-goose* wheat. It derives its latter name from a story, which is current in the north, that four or five kernels, from which the American stock has proceeded, was found in the crop of a wild goose, which was shot about four years ago, on the west shore of Lake Champlain. It is called *reed* wheat from the great strength of its straw, which serves to prevent its being prostrated in the field.

The first notice we have of this species of wheat in the United States, is in the Memoirs of the Philadelphia Society for Promoting Agriculture. A parcel of it was received in 1807, by the society, from Gen. Armstrong, then our minister at Paris. This grain was grown five or six years by Judge Peters, and proved to be very productive; a pint of seed, sown in drills and hoed, giving one bushel and a peck of grain. But we find the judge saying, after three or four years' trial, that it had not "thriven so as to encourage extensive culture." In a more *southern* latitude, he expresses a belief that it would do well. It was extensively distributed; but from our not having heard more about it in the last twenty-six years, we believed it had not proved a valuable accession to our husbandry.

We have seen beautiful fields of this wheat. We sowed a sample specimen two years ago, but on being assured by a friend that it was inferior for flour, we gave it up. In the Philadelphia edition of the Domestic Encyclopædia, printed in 1821, we find it stated, that this kind of grain does not yield so much flour or meal as any of the other kinds of wheat, and that "the flour is scarcely superior to that obtained from the finest barley."

Having said thus much, which we felt bound to say in the line of duty, as to the character and introduction of this grain into our country—it remains only for us to add, that the seed may be procured of *our* friend Mr. Thorburn, at *five* dollars a bushel.

Harrowing Grain.—This is the proper season to call the attention of farmers to this subject, as the operation should be performed as soon as the ground is sufficiently settled to bear the cattle. We have published several articles, showing the manifest utility of spring harrowing winter grain, and explaining the why and the wherefore. The harrow should be light, and if the teeth are long, it is well to intertwine a few branches of pine or other wood among them, to prevent them cutting too deep. The operation closes the fissures caused by the earth contracting as it does, pulverizes and opens the surface to the genial influence of heat and moisture, and, by covering the crowns of the plants, causes them to tiller more abundantly. We advise, that *in every case*, eight or ten pounds of clover seed be sown to the acre before the harrow is introduced. It will more than repay the expense of seed, in the fertility it imparts to the soil, to say nothing of the value of the herbage for farm stock.

Trimming Hedges.—Anderson, who is good authority in agricultural matters, makes this an essential rule in clipping hedges: *not to cut the top of the* STEM, *until it has acquired sufficient stability to resist even a bull.* The sides are of course to be clipped, in a sloping direction, so as to give the hedge a conical form.

Meteorological.—The mean temperature at Albany, from Dec. 26, 1837, to January 24, 1838, was 32°, 96′. During the same period in 1836–7, the mean temperature was 14°, 96′,—showing the remarkable difference of 18 degrees in the temperature of the seasons. On referring to the meteorological tables for the eleven years previous to 1837, it appears that the mean temperature of 1836 was about two degrees colder than that of any of the other eleven years, and eight degrees colder than the mean average of the whole period. We have not seen noted the mean temperature of 1837, but it was probably lower, some two or three degrees, than even that of 1836; or this at least must have been the case during the summer months, as many garden productions, as melons, egg-plants, grapes, &c. were more backward in ripening, and even indigenous seeds, as the butternut, walnut, three thorned locust, &c. did not attain to that maturity which they reached in 1836. On consulting the meteorological tables for past years, there appears much to warrant the opinion, that we have had a succession of cold, and afterwards of comparatively warm seasons. We had a succession of cold seasons subsequent to the great solar eclipse in 1806; another succession of them in 1816 and the following years; and the last few years have been progressively growing colder up to the present period. Whether the present mild winter is indicative of a favorable change, we do not pretend to conjecture. We give below the mean temperature of the last eleven years, as copied from the Academic Report of 1836:

1826 ..	51.07	1830 ..	50.65	1834 ..	48.53
1827 ..	48.62	1831 ..	49.15	1835 ..	46.17
1828 ..	51.36	1532 ..	48.10	1836 ..	44.73
1829 ..	48.20	1833 ..	47.62		

The conversion of Winter into Spring Wheat is effected in this way: When sown in the spring, winter wheat is said to send up only a comparatively few seed stocks, the lateral shoots will be weak, and the crop consequently light. If the seed from this, however, be sown the next spring, it will throw out stronger stems, will tiller with more luxuriance, and, if the operation be repeated in the following year, it will then be found converted into summer wheat.

A sample of the products of the New Husbandry.—"In the year 1810," says the late John Lorrain, in his System of Husbandry, "besides soiling forty head of cattle and seven horses, the following products were obtained from eighty-five acres of land, to wit:

1750 bushels of potatoes.
817 do. Indian corn.
222½ do. barley.
60 tons of hay.
1391 loads of manure, of 32 cubic feet each.

The manure, however, was the product of winter as well as summer feeding. The above product, without enumerating the value of the dung, was estimated at 2,799 dollars"—p. 312—equal to an average product, lacking a fraction, of $33 the acre.

Dutton Corn.—There is nothing good and commendable but what has its counterfeit; and we regret to notice, that some late agricultural writers would not only make us answerable for the faults of the counterfeit, but responsible for the impositions which have been practised upon Mr. Thorburn, our worthy seedsman. Having cultivated the Dutton corn eighteen years, *without having it once materially injured by frost*, we ventured to recommend it as an excellent and *early* field variety for our latitude—but not as the *earliest* variety of corn. But it seems our neighbor Thorburn has sold seed, as Dutton corn, which was not early. It is proper to say, that *our* seed forms but a small portion of what Mr. Thorburn sells—and is generally off his hands early in January. Mr. Wm. Thorburn has been imposed upon, and has bought and sold seed, as Dutton corn, which was not such—and which he afterwards ascertained either did not grow, or did not ripen early. We have nothing further to offer in support of our opinion in regard to this variety of corn, than the numerous testimonials in its favor from our correspondents, published in the volumes of the Cultivator.

Baden Corn.—To those who have applied to us for *Baden Corn*, we remark, that the seed is not to be had in this neighborhood, and probably not north of Philadelphia or Baltimore. We cultivated a few hills, but it lacked some weeks of coming to maturity when the frost killed it. It will not ripen, we think, in New-York.

Texian Corn.—We have received samples of this from Harrisburgh and from North Carolina. Each kernel is enveloped in a husk—the grain is handsome, but light. We have tried it. It will not ripen in our climate.

Deterioration of Soil.

Our misfortune has been, and still is, we do not properly appreciate the exhausting influence of our system of husbandry upon the fertility of our soil. There are many in the fertile west who affect to believe, that their lands will bear constant cropping with wheat, or wheat and clover alternately, and who hence disregard their manures, the primary source of fertility.—The pioneers in the valleys of the Hudson and Mohawk once, no doubt, thought the same, and acted, or practised upon this belief, till made sensible of their error by the contrast in the products of old and new lands. Although many have now become sensible of the ruinous effects of the old system, but few, as yet, have commenced the needed reform.

In regard to West New-York, where we admit the soil is naturally more fertile, and more abiding in fertility, than the lands originally were in the eastern part of the state, we have pretty good evidence that the fertilty is diminishing, especially where wheat is made the continued object of culture. Thomas Burrall, Esq. has a most excellent wheat farm in the neighborhood of Geneva, which he began to clear and improve twenty-one or twenty-two years ago, and on which he has made and applied much manure. Mr. Burrall informed us, in the summer of 1836, that he had noted down the average product of his wheat crop every year; that dividing the 20 years into three periods, he found that his wheat had averaged 29 bushels per acre during the first of these periods, 25 bushels the acre during the second, and but 20 bushels the acre during the third period—[illegible] showing a diminished fertility of nearly one-third, under what may there be denominated a good system of husbandry.—We do not precisely know what Mr. Burrall's practice has been; but we presume that if it has been faulty, the fault has consisted in making wheat the great and primary object of culture, thereby impairing the amount of its specific food; and that a remedy for the evil would be found, in cultivating other crops more, and wheat less. At all events, his experience admonishes wheat growers, that their lands will deteriorate, if they return this grain too often to the same field.

Judge Cowen's Report,

On the propriety of introducing elementary books upon agriculture into common schools, made in pursuance of a resolution passed in the agricultural convention.

The committee to whom it was referred to consider the propriety of introducing books which treat on agriculture into district schools, respectfully report,

That so far as reading lessons on agriculture can be properly introduced into common schools, your committee are not aware that the books now used there are deficient. Such schools are not the places for learning the practical details of any business or profession. The utmost that can be done is by short, easy and interesting lessons to create an appetite for and a skill in general reading. School books in that line should therefore be of a miscellaneous character, having reference in a degree to the virtues which pertain to the agriculturist in common with others; industry, frugality, integrity, &c. If they be deficient in any respect, it is perhaps in not inculcating sufficiently at large the peculiar advantages enjoyed by the farmer. Beside mastering his appropriate reading lessons, the scholar is put to his geography, history, &c.; and these, when added to his spelling, writing, grammar and arithmetic compose about the sum of learning which the common farmer ordinarily can bestow upon his son consistently with the diligent pursuit of his business; and a thorough knowledge of these rudiments is about all which the son can acquire. Even this must be done in those intervals which can be allowed from the service of his father; and he is then left till he reaches full age, and for the remainder of his active life, to his own efforts for improvement upon the foundation thus laid.

He has already acquired a knowledge of the essential branches of his profession while laboring for and under the tuition of his father; and, in the usual course of things, will make a competent, perhaps a good farmer in the ordinary acceptation of the word. To make him more, it is at this stage, we apprehend, that agricultural books should be put into his hands. He now, in an educational point of view, has two objects before him. His primary object is that course of instruction which will make his profession available to its utmost extent in bettering his fortune; his secondary is that more general improvement of the mind which is to fix his intellectual rank among his fellow-citizens. The latter is of course left to his taste, his means and his leisure. But the former is a mean by which this common farmer ought to be enabled, in the course of a few years, to double his capital and the nett profits of his business by the additional knowledge which he brings into it, without adding a single acre to his domain. We assume that all this is feasible, even supposing him to be placed where a majority of our agricultural population now stand, on a farm exhausted of its primitive fertility. The history of agriculture will here teach him that soils naturally worse and more reduced by neglect, in a climate less favorable than his own, and in countries borne down by rent and taxes, have, by the application of that very skill which, by due attention, he can easily acquire and apply in his turn, been raised to greater strength than his own land possessed when first reclaimed from the forest, and put under cultivation, with all the vigor of its vegetable mould. Being capable of reading and understanding so much, and of studying and finally mastering the details by which such a result has been accomplished, and being, moreover, stimulated by considerations of personal gain, he will successfully aim at a similar result in his own case, if the requisite means of instruction be placed within his reach.

Such a great desideratum in the most important branch of national industry, never has been and never can be placed below the anxious notice of an enlightened legislature; and their refusal to act can be accounted for only by doubts concerning the means which are proper for promoting it. State and county agricultural societies have heretofore been formed, and are again proposed by some; by others an agricultural college, to be connected with a pattern farm. We have witnessed the operation of the former on an extensive scale and under vigorous legislative patronage. Although they proved to be useful in a high degree, yet many complained that the promised results would by no means warrant the continuing on foot such a cumbrous, troublesome and expensive machinery. The effect of the latter has not yet been seen. It is not to be denied that it may do well in what would be called the higher walks of agriculture; and in time extend its influence to the rank and file of the profession. But the whole army should be disciplined by the speediest methods. It is on an extended scale only that agricultural skill can be felt as a national benefit; and it is feared by many that its diffusion through such a medium as a college must be indirect, slow and perhaps, after all, stop short with but a small portion of community.

It appears to your committee that we should, therefore, as far as possible, avail ourselves of what may not improperly be called a *common school of agriculture.*—This may, as we believe, be done by placing more within reach of our intelligent yeomanry such books as insinuate agricultural instruction in a plain and practical way. We cannot doubt that such a method would be decidedly effectual with all that class of young men, already very numerous, who have been educated in the manner we have before mentioned. We may assume that their course of life has formed them to habits of application and disciplined them in the manipulations of farm-labor; and though, so far, trained in some respects on an imperfect plan, their minds are not yet shackled by prejudice in favor of a slovenly and negligent system. They have at home the advantage of theory and practice, of an intimate connection between reading and action, the acquisition of book knowledge and the means of applying it in their own business. In short, the family of such a man, his own fire side is his school of study, and his farm a laboratory where his learning not only may be instantly applied but turned to account.

Such is the only true system of instruction in other professions. A distinction is carefully kept up between the preparatory and professional education of the student. In the latter it is deemed essential that he should be put to practical details as well as reading; and his progress is very commonly measured by the diligence of his application, entirely independent of the character of his instructor. Give him the stimulant of necessity, his books and his field of exertion, and he will be sure to make good progress under the most careless tutor. He is put into a vigorous course of *self-education.*

Something much like this is already apparent among us, with those who may be called students in the profession of agriculture. A spirit of inquiry has been aroused, and evidences of improvement have, within a few years, presented themselves, more striking in character and aggregate than could be collected in the history of many years before. It is true these evidences are yet but sparsely exhibited; and it is to be lamented that they are far from being numerous enough to countervail the delusive encouragement heretofore holden out to the more splendid but less useful branches of industry.—The fact, however, presents itself; and your committee feel at no loss in attributing it to the more extended introduction of agricultural books among a reading community. The more conspicuous instances are obviously connected with the recent establishment of a periodical paper called the *Cultivator* at the city of Albany. This paper has been remarkable for its steady series of well selected lessons, with various information on the subject of agriculture, imparted in a plain and familiar style, and withal for so moderate a price as to be accessible like a common school book. Up to the time of its appearance, so low was the state of agricultural knowledge, that a great portion of the old and long cultivated parts of the state were surrendered in the minds of the proprietors, to a course of hopeless deterioration. Such gloomy prospects have been dissipated, confidence has succeeded to despondency, and has acquired steadiness mainly by carrying into practice the suggestions derived from the *Cultivator*. The Genesee Farmer, also, a paper conducted on similar principles, but with a more particular view to the western part of the state, has exercised a like influence within the sphere of its circulation.—The able conductors of these papers have eviscerated from numerous and ponderous volumes, such portions of instruction as they believed would best subserve the wants of our general farming population, and sent them forth modified by their own local experience and information, and divested as far as possible of every thing technical or obscure. They have placed the professorial chair in the farm-house. Their success has added to the number of instances, in which, since discovering the art of printing, the practice of assembling in organized classes for the purpose of acquiring knowledge, may be dispensed with. Ten thousand eyes can now be simultaneously turned to almost any branch of instruction, more easily, cheaply, and with greater effect than one hundred could before. The wealthy farmer can avail himself of a full library, both European and American. But the ingenious purveyor of the periodical press has, we think, demonstrated, that, if his system be properly followed out, the distinction between the greatest and the most humble means may, in this respect, be nearly annihilated. To resume the figure we before used; the power of this press can be made most rapidly available in arousing the *esprit du corps,* in contributing the material, and perfecting the discipline of our whole agricultural force.

Your committee have adverted to the two papers mentioned, because to us at least they present the most striking instances in favor of the proposition we mean to submit. It is no slight evidence that by individual means of this kind, a good school is already established. We see from what has been done that it has taken the most appropriate form; and the inference is not less certain than it is gratifying, that such an effort properly encouraged, will eventually bring up the energies of our farming population to a par with what may be seen in the best cultivated regions of Europe. The object should be here as it has been there, to add to the intellectual power of the common farmer, and direct it into the line of his profession. The inductive philosophy of agriculture should be snatched from its hiding places and presented at the door of the cottage.

While, therefore, your committee disapprove the introduction of books on agriculture into common schools for children, they have not thought it impertinent to distinguish the circumstances under which, in their opinion, such books may and should be used. And they would suggest whether, among the various plans for agricultural improvement which have been submitted as worthy of legislative encouragement, the multiplication of such useful publications as have been found to answer the wants of our yeomanry, does not present high pretensions. Notwithstanding their present circulation, (and the committee are rejoiced to believe a circulation which not only has fully indemnified the proprietors, but will continue to do so) there are doubtless yet many parts of the state where they have not been introduced. One method of supplying the defect would be by new editions to be put in the market at a moderate price; or a copy might be placed at the expense of the state, with the clerk of each school district, to be open at his discretion for perusal by his constituents. Various other and perhaps better systems of distribution may occur should legislative attention be thought due to the subject.

Respectfully, E. COWEN.

The Mulberry and Silk Culture.

We call the attention of our northern readers, who are disposed to embark in the silk business, to the plan of rearing the Mulberry, practised by a correspondent in Michigan, as mentioned in a former number of the Cultivator, viz: to cultivate them in stools, and not as trees. To do this, seedlings of a years growth are chosen. The whole ground is ploughed; the plants are laid in the furrow, in a sloping direction, so that the top of the stem shall, after a furrow has been turned upon the plants, project a little above the surface. The plants may be laid in rows at six to nine feet apart, and like intervals between the rows. Nearly every bud will grow and become a shoot; and consequently there will be stools of several stocks instead of a single stem. The advantages of this mode of culture are,

1. The leaves are more readily gathered than from trees;
2. There will be more and larger leaves, because the system of roots will be larger in a stool than in a single tree, and the growth consequently more vigorous;
3. More leaves will be obtained from the same area of surface; And
4. And principally, if the winter kills the tops, wholly or partially, the dead parts can be easily cut away, and a new and vigorous growth ensues—because the roots are seldom injured if planted on dry ground. In case the tops are killed, it will only be necessary to retard somewhat the hatching of the eggs, till the growth of the new sprouts is somewhat advanced.

In this way it is probable the multicaulis may be rendered useful in the northern counties, or they may be cut down in the fall, and the stumps covered with litter or earth. In the mean time we would recommend more attention to the culture of our native red mulberry, which is hardy. The fruits ripen in midsummer, when they may be easily saved for seed.

Proceedings of Agricultural Societies.—We have received the proceedings of several societies, and anniversary addresses, for publication. All of these possess a local, and many of them a general interest.—But it will be perceived, that as the Cultivator has a national circulation, were the practice of publishing these proceedings gone into, all might claim an equal participation in our columns, and at particular seasons would entirely engross them, to the exclusion of other matter, of more general interest. We hope these considerations will serve as a sufficient apology for what might otherwise be considered in us a want of courtesy. There are probably fifty or sixty societies who would have an equal claim to our columns; and as we cannot gratify all, we are compelled to deny all, except so far, as in our judgment, these proceedings possess pre-eminent merits.

The ruta baga crop possesses an advantage over other root crops, not only in the shorter time it is upon the ground and requires nursing, but from the greater facility with which it is harvested. Mr. Hollis, of Butternuts, pulled and topped 214 bushels in three hours and fourteen minutes. It will require at least eleven days for a man to harvest this quantity of potatoes. The mode of proceeding was, to draw a turnip with each hand, and lay them in rows, the roots to the drills; and then return upon the next row, in the same way, thus bringing the tops of both rows together. In topping, the tail of the root was slightly raised with the left hand, while with the right, armed with a heavy knife, the top was severed with a blow.

Carrots.—We are gratified to learn, that the field culture of this root is rapidly increasing, and that several farmers are successfully feeding them to fattening animals.

Oat Pasture.—We find in the second volume of the Transactions of the Philadelphia Agricultural Society, an interesting communication from William Young, of Delaware, describing the mode which he had successfully adopted, of renovating lands, which had become so exhausted as to be "incapable of producing any crop." This was effected by "ploughing and sowing, for the purpose of producing pasture, and an accumulation of vegetable soil." For this purpose wheat, rye, Indian corn, buckwheat and oats were severally tried, and the latter adopted as the best. The soil was a cold heavy clay. His practice was to sow oats as early as possible in the spring, upon land ploughed in the fall, or in fields which were in pasture or oats the preceding autumn. These afforded early feed, and were fed till July or August, when the ground was reploughed, and again sown with oats; and these last afforded pasture from early Sept. to Dec. Fertility was so far induced by this practice, that clover could be grown the second or third year. And when once in luxuriant clover, says Mr. Young, "there is no farmer at a loss how to make his fields as rich as he pleases; and having got them into good heart, *it will be his interest to put them in such rotation as shall increase the vegetable soil, and consequent fertility of his fields.*" We beg the reader here to remark, that the great object of this excellent manager was, to make his fields grow clover—this attained, he considered further improvement easy. How much easier is it, to *prevent*, than to *cure*, barrenness? There is much land in the Atlantic states, however, so exhausted by bad husbandry, as to be incapable of growing clover. Mr. Young points out a mode by which it can be reclaimed, in a practice of some years; and on fields where no crop would grow, he, by his mode of management, maintained a dairy, fattened beef, and produced good crops, without the aid of any extraneous manures. Mr. Young's letter will be found at p. p. 187 to 199. Those who would profit by his example, should consult his whole practice. Dr. Mease bears testimony to the correctness of Mr. Young's statements, having visited his farm in 1806 and 1808.

Sheep-killing dogs.—"A young dog, having wantonly bitten and mangled a large lamb, so that it died, was muzzled by one of my servants, and tied to the dead lamb, for a day and a night, and severely beaten. He was entirely cured of his propensity for chasing sheep, and would never afterwards approach them."—*Judge Peters.*

The Veterinary Art.

We have been favored with an essay on the veterinary art, by P. A. Brown, L. L. D., of Easton College, Pa., "setting forth its great usefulness, giving an account of the veterinary colleges in France and England, and exhibiting the facility and utility of instituting similar schools in the United States," &c.

As it is not generally known what is implied by the term veterinary art, we make the following quotation from Dr. Brown's essay by way of explanation.

"The word SCIENCE, in its most comprehensive sense, means *knowledge;*—in its general acceptation it is "knowledge reduced to a system;' that is to say, arranged in regular order, so that it can be conveniently taught,—easily remembered,—and readily applied to useful purposes.

"An ART is the application of knowledge to some practicable end,—to answer some ornamental or useful purpose. The arts are divided into the *fine** and the *useful.*

"If the knowledge be merely accumulative experience, the art is called empirical; but if the knowledge is experience, guided by reason,—based upon general principles,—and brought under their control, it is a *scientific art.*

"Veterinary comprehends a knowledge of the external form, as well as the internal structure and economy of domestic quadrupeds, the appropriate management of them, and the nature, causes and cure of their diseases.

"The VETERINARY is "a SCIENTIFIC ART" in the strictest sense of the term. It invites its votaries to the following studies, viz:—

"1st. The different *species*, and various *races*, of domestic animals;—their different *breeds;*—the uses to which each breed is applicable;—the useful crossings of breeds; and the most economical and best methods of *producing*, *raising* and *feeding* each class and breed.

"2nd. The *breaking*, *educating*, *training*, and *fattening* certain domestic animals.

"3rd. *Commercial jurisprudence*, as regards domestic animals; including the uses to which can be applied, to the best advantage, their *flesh*, *hides*, *offal of their hides*, *tallow*, *hair*, *wool*, *horns*, *teeth*, *hoofs*, *entrails*, *blood* and *bones*.

"4th. The study of the *outward forms* of domestic animals, pointing out their *beauties*, marks of *strength* and *speed*, and their *defects;* together with the methods of ascertaining their *ages*.

"5th. The *internal structure* of domestic animals; their *anatomy;* their *comparative anatomy;* and the most humane and economical methods of making use of their *speed* and *strength*.

"6th. The various *foods* used for the nourishment of different domestic animals;—the different methods of *raising*, *curing* and *preserving* them with the greatest economy, and in the greatest abundance.

"7th. The various *medicines* required for domestic animals;—the most approved methods of *raising*, *curing*, and *preserving* those that are *botanical;*—a general knowledge of those that are *mineralogical;* together with the manner of *mixing*, *preparing* and *administering* both those that are botanical and those that are mineralogical.

"8th. The most effectual methods of *preserving* domestic animals from *contracting diseases;* and the most approved means of *curing* those that contract diseases; together with methods used to prevent *contagion* and *infection* among them.

"9th. The most approved plans for preserving domestic animals from *accidents* and *injuries*, and the performance of all kinds of *surgical operations* upon those that require them.

"10th. The most approved methods of *shoeing* certain domestic animals; either generally, or when diseased or lame."

Such are among the important and useful studies which would be taught in an agricultural school.—Those which appertain to mechanics, in the construction and application of farm implements;—to tillage, embracing the economy of manures, the adaptation of crops to particular soils—alternation of crops and root culture;—and to the department of horticulture, embracing the useful and the ornamental—fruits, or vegetables and flowers—their propagation, culture and preservation—all these, we say, would form branches of instruction in rural affairs, of perhaps as great importance to the individual and the community, as those that have been recapitulated as belonging to the veterinary art.

In giving an account of the Veterinary colleges in France and Great Britain, Prof. Brown has omitted to notice the eminent school in Edinburgh, under Prof. Dick. There are three veterinary colleges in France, at Lyons, Altfort and Toulouse. That at Altfort has 300 students, six professors, costs the government about 124,000 francs, about $22,000, per annum, including the interest on the capital of 100,000 francs, invested in the farm and buildings. The school yields an income to the government, in return, of 198,000 francs. This school is furnished with a library, of three or four thousand volumes, principally veterinary, agricultural and natural history; a very extensive gallery of anatomical preparations; an hospital for the reception of sick animals, and for practical instruction; a botanic garden, in which there are upwards of 800 species of plants scientifically arranged, and a farm, large enough to instruct the students, practically, in the culture of all the plants employed in the nourishment of domestic animals, as well as all those used as their medicines. This abstract will serve to give some idea of the wise provisions made by monarchical governments to improve the condition of their agriculture. We gave in our last another evidence, in the policy adopted by the Great Frederick of Prussia, who annually expended upon agricultural improvements more than a million of dollars, and which he considered as "manure spread upon the ground," and which did not fail to make him a liberal return. Will republics be the last to appreciate the value of these stimulants to agricultural labor, and the last to apply them? We are already seriously suffering from this neglect, by being obliged to import bread-stuffs from Europe to subsist our population.

Prof. Brown, closes his essay with an estimate of the expense of establishing a Veterinary college in the United States, and a proposition to make such an establishment. He estimates the cost at $47,500, viz. 125 acres of land, at $100, making $12,500, buildings $30,000, and library and apparatus $5,000. He proposes to raise $50,000 by subscription, in shares of $50 each, and to extend certain privileges to subscribers.

Dr. Ives on Horticulture.

We have received a pamphlet, entitled, "Extracts from an address delivered by Prof. Eli Ives, before the New-Haven Horticultural society, Oct. 1837," embracing a list of the premiums awarded at the annual exhibition, and a list of the officers and members of the society.

It is highly gratifying to see the men of the schools honoring rural labor, by studying to enlighten, to encourage, and improve its condition, and to see them dignifying these pursuits by adding example to precept. We may say, in the spirit of Cicero, when eulogizing Socrates—these men bring down science to our wants, domesticate it in our dwellings, in our gardens and on our farms—ruralize it, and render it more familiar, more useful in common life, and more in the reach of common capacities.

The following extracts will serve to show, that the professor justly appreciates the benefits, to the mind as well as to the body and the appetite, of horticultural pursuits.

"GENERAL REMARKS.

"Horticulture, in its simplest form, treats of the improvement of the qualities of vegetables, flowers and fruits; or, in other words, it is the art which comprehends the various methods of producing all sorts of fruits, vegetables, roots, herbs and plants, for the support and luxury of mankind. It is the most perfect and productive mode of cultivation, confined, comparatively, within narrow limits. In its higher departments, it assumes the character of the elegant arts, and teaches the disposition of grounds and gardens."

"MORAL TENDENCY OF HORTICULTURE.

"The practice of horticulture has a happy influence on the morals of the community. The contemplation of whatever is beautiful serves to refine the taste and elevate the mind. The beauties of the fine arts, painting and sculpture, may find a substitute in the forms of vegetable life not less curious or beautiful. The beauties of the garden are within the reach of the great mass of the population.

"It becomes the philosopher, the politician, the moralist; indeed it is incumbent on all classes of society to encourage gardening in our republican country. Every community must have its amusements;—those of a moral tendency should be preferred. The objection on the score of morals, brought against some of the amusements of large cities, cannot be urged against horticulture. It is believed that a public exhibition of fruits and flowers every month, in those parts of the year which are favorable, would have a good moral tendency, and excite emulation among the cultivators, and would be accompanied by a very trifling expense, if a general interest were once excited."

After remarking on the history and objects of the society, and citing instances of horticultural taste and industry in eminent men, Professor Ives gives the following illustrious example, in the late President Dwight, of Yale College.

"He had the largest garden, the best culinary plants, and the finest fruits in the city, and all cultivated by his own hands. This fact will excite surprise, when it is recollected that he delivered a lecture to his class six days in a week—performed the duties of Professor of Divinity, and superintended the government of the college. He was the first in this city who cultivated the strawberry extensively and successfully. He demonstrated that an abundance of delicious fruit might be cultivated at a very little expense. He was a minute and accurate observer of the habits and laws of vegetables, and delighted in conversation to give or receive instruction in horticulture. He infused into his conversation, music and poetry, and was listened to with delight, even when his theme was the cultivation of cabbages. He taught that the proper time to prune fruit trees, *was in June*, when the plant was in the most rapid growth; and the reason was, that the wound will heal most readily at that season. Dr. Dwight, was enabled to perform so much and so various mental labors, by invigorating his constitution by exercise in the open air. No one felt more strongly the sentiment of the poet—

> "The idler is a watch that wants both hands,
> As useless when it goes as when it stands.
> Want of occupation is not rest;
> A mind unoccupied is a mind distressed."

Mention is made of Gov. Edwards having reared more than forty seedling pears, all of which may be denominated rich, and some of them very delicious. Reference is then made to Dr. Van Mons, and his theory and practice, in the paragraph we here quote.

"Slow and uncertain is the advancement of every science and art, unless aided by principles founded on inductive reasoning. This assertion is verified by the discoveries of Prof. Van Mons, in relation to the causes of the varieties of fruits and flowers. He commenced planting in a garden in Brussels, seeds of roses and other shrubs;—planting successive generations with a view to observe the variations. Afterwards he began with the seeds and stones of fruit. By means of a series of experiments with the seeds of flowers and fruit, he arrived at the following conclusions: so long as plants remain in their natural situation, they do not change, and their seeds always produce the same, but by changing their climate or territory, they commence varying from their natural state, and never return to it, but are removed still farther by every successive generation. It is not so much the effect of climate as of cultivation. In a state of nature, seeds do not improve or degenerate; but he remarks that the seeds of old trees produce trees more like the original or wild plant, than seeds from a young tree. Hence he recommends to plant the first seeds of a new variety, whether fruit trees or flower, if it intended to improve a variety. Another important fact for the cultivator of fruit is this; that the seeds of the fruit of young seedlings will produce trees which will bear fruit much earlier than the seeds obtained by planting the seeds of old trees. He also gives directions by which to discriminate those plants which may be expected to produce good fruit, from those which will produce bad or inferior fruit. The improvement in the quality of the fruit is at the expense of the life of the tree: Those trees which produce the most delicate fruit are short lived. The seedling pear trees of Professor Van Mons, of the eighth generation, bore pears at the age of four years. Double flowers he does not consider a variety, but rather a sign of feebleness. An augmentation of any part of the flower, is accompanied by a paucity of fruit.

"For almost half a century he has been pursuing his labors, disseminating new and healthful varieties. He remarks, that his intention has not been to establish a science, but to do a good act, which would be useful by the dissemination of good fruit."

Dr. Van Mons is entitled to the credit of not only doing good acts himself, but of causing good acts to be done by others. He has not only produced and disseminated many new and choice varieties of fruit, particularly of the pear, but he has awakened the zeal of others, who have been successful in obtaining like results. Among the new pears of high repute, produced by Van Mons, most of which are now growing, and many of them have fruited in the United States, we may enumerate the Beurre Diel, which is in eating from November to January; the Napoleon, at maturity in November; Maria Louisa, ripening in October, besides many others of proved excellence. The *good* varieties which Van Mons has produced it is said amount to three or four hundred.

---

*The fine arts are architecture, painting, sculpture and engraving.

Highland Agricultural Society of Scotland.—Some unknown friend has kindly sent us the Scotsman, printed at Edinburgh, several columns of which are occupied with an account of the meeting of this society at Dumfries. There were more than two hundred cattle entered for premium, of the Galloway, Short Horn, Ayreshire, and other breeds; more than 500 sheep, besides horses, swine and other domestic animals; many new implements, seeds, grains, roots, &c. The Messrs. Lawsons, who have one of the best arranged seed establishments any where to be found, and who have been justly commended for their zeal and taste in getting up an agricultural museum, exhibited several new seeds of wheat, barley, oats, &c., which promise to be an acquisition to husbandry; they also exhibited the Rohan potato. But what strikes us as particularly characteristic of Scotland, is the interest which the leading men of the nation—the nobility, clergy and men of fortune—take in these associations, and the encouragement they impart to them by personal attendance at their meetings, as well as by pecuniary contributions. And we observe, that on this occasion, many gentlemen, of distinguished agricultural repute, attended from England, Ireland, and a deputation from an agricultural society in France.

Two experiments were made by Hart Massy, Esq. of Watertown, Jeff. last spring, according to the Watertown Standard, one in his corn field, and the other in his orchard, which produced uncommon results.—He planted five rows in his corn field with seed soaked in a solution of salt petre,—and the product of these five rows was greater than the product of 25 like rows along side, similarly treated in all respects save in preparing the seed. The steeped corn was not touched by the worm, while the rest of the crop was nearly destroyed by them. We have been in the habit of dissolving salt petre in our steep for seed corn, for many years; but as we have steeped it *all*, we are not able to judge of its *comparative* advantages.—Great benefit has been ascribed to nitre, in the preparation of seed wheat as well as corn, in communications from Robert Johnson and Dr. Graham, formerly senators, to the old society of agriculture, &c.

Mr. Massy's other experiment was to scatter plaster upon the blossoms of an apple tree, which had been shy in bearing—and had never given over two bushels of fruit. The tree bore almost twenty bushels, presumed to be caused principally by the gypsum. The fecundation of the fruit blossom is effected by the pollen of the male organ coming in contact with the female organ. Whatever prevents this contact, as strong winds or heavy rains, renders the blossoms abortive. The female organ in this case, could not have been rendered fertile by the mere contact of the plaster; but this might have operated beneficially, by adhering either to the pollen, and thereby rendering it less liable to be blown or washed away; or to the stigma of the female organ, and causing the pollen to adhere, when it chanced to fall upon it.

Vetches.—Vetches, sometimes called tares, are extensively used in England as a green crop, to be cut and fed green, like luzern and clover, to working and other cattle. They are of two kinds, winter vetches, sown in autumn, and cut in the spring, and summer vetches, sown in the spring, and cut at mid-summer, in time to sow the ground with winter wheat or rye. The late Chancellor Livingston made experiments in cultivating them as a fallow crop, in 1794, and the result is recorded in the memoirs of the old society.—Sown upon a light loam in May, and plastered, they produced a good crop. They were cut when in bloom, in August, and cured like hay. The product was about 25 cwt. Three bushels were sown upon a slaty gravel and plastered. These were intended for seed; but continued to grow, while the seed at the bottom was moulding and wasting; they were five feet long in October, but only three pecks of seed was obtained. The summer vetch has been tried in this neighborhood. It gave a great product in vines, but very little seed. Cattle are fond of them; and if the seed could be readily procured from abroad, they might no doubt be profitably cultivated, on a small scale, for working cattle or milch cows, particularly in the vicinity of large towns, where pasture is scarce.

Cuttings and Grafts, intended for propagation this spring, should be made before the buds begin to swell. They may be preserved in the cellar, or buried in the ground till wanted. Cuttings of the grape, currant, gooseberry, quince, &c. should be cut square and smooth, at a joint or bud, and the former should, if convenient, embrace half an inch of old wood, that is, wood two years old. Four eyes are enough to a cutting, of well ripened wood; and all the buds save the upper one, may be inserted under the surface; and in the grape the upper bud may be slightly covered with loose earth. All cuttings strike best in a sandy soil, which is not wet; and where sand does not exist, it is well to throw a handful into the hole where it is designed to place a cutting. See pages 6 and 138 last volume.

Correspondence Condensed, &c.

We are obliged, from the number of communications on hand, to give a portion of them in a condensed form, or to content ourselves with a sort of summary of the matters which they embrace. And here we are disposed to remonstrate against a growing evil—that of communicating or asking information under false names. We verily are disposed to be more accommodating to gentlemen who give us their proper names, than to those who are anonymous, although we mean to be civil to all; and we believe the public are much of our way of thinking. Gentlemen who are able and willing to advertise the public of what they believe, or know, to be useful, will very much enhance the value of the obligation, by giving it the sanction of their names. It is creditable—it is highly praise-worthy—to enlighten and instruct our fellow-men, in whatever may tend to improve their condition in life; and the public are apt to think, that those who are not willing "to take the responsibility"—by giving their names, are either influenced by a false modesty, or distrust the information which they offer for the guidance of others. But to our task.

ROOT CULTURE.

We have a score of queries from an anonymous correspondent in Tennessee, in regard to the culture of roots, a subject on which we have endeavored heretofore to be full and explicit. Among them are the following—

1. *Can the root culture be brought to as high a degree of perfection, and cultivated to as great an extent in the present state of labor, as in England?* We answer in the affirmative—as much as any other branch of tillage husbandry. Labor costs more, but land costs less, with us; while the excess, if any remains, is counterbalanced by the rents, tithes, and poor rates, which the English farmer pays more than the American farmer. We are neither deficient in climate nor soil; but we are deficient in good implements and good culture. The expense of securing the turnip crop during the winter, though not great, when custom has rendered it common, is in a measure saved to the British farmer. But we do not think the culture requires to be as extensive here as in Great Britain, as, from the extent of our lands, compared to our population, winter forage is cheaper here and more abundant, than there. And besides, our Indian corn crop is a great source of winter cattle food, and of excellent food when properly secured and fed out, which the farmers of Great Britain cannot command. The ruta baga can be raised here as a second crop, after clover has been taken off; there it cannot. It can be raised here, under good management, at *four* cents the bushel. These facts will enable the farmer to decide, after a fair trial, how far root culture is adapted to his soil, his location, and the profits of his business.

2. *In what soils do they best flourish and give the most abundant product?* And,

3. *Which is the most profitable for stock, ruta baga, mangold wurtzel, or sugar beet?* The ruta baga does best on good sands, gravels or light loams; the beets on loams, either of sand or clay. Both require dry soils and rich soils; and long manure, spread and ploughed under, may be economically applied to either. We think the Swede ordinarily gives the largest crop, demands the least expense in culture, in harvesting, and securing for the winter; and according to the tests which have been accurately made in Scotland, it is rather superior to mangold wurtzel for feeding stock. The beet requires to be sown early in May—the ruta baga may be sown from the middle of June to the middle of July, according to latitude; and of course the former requires from six to eight weeks longer tending than the latter. The difference between the sugar beet and mangold wurtzel for cattle, it is presumed is not material. The latter will ordinarily give the largest crop, but the former contains the most saccharine or nutritious matter.

STARCH AND SUGAR.

W. Edwards, of Lima, who will please accept our thanks for his friendly offices in our behalf, asks us to publish the process of making potato starch, and also the process of converting this starch into sugar. We comply as far as it is in our power.

To make potato starch.—Wash the potatoes, and grate them into water, for which latter purpose a large grater should be procured from the tin-man; or, if on a large scale, the potatoes may be reduced to pulp in a grater cider-mill. Then take out the refuse pieces, if any, with the hand, and next strain the whole of the water in which the potatoes have been grated through a thin cloth, rather coarse, or fine sieve, and afterwards frequently put on and pour off water, until it comes clear from the starch, which is always allowed to settle or fall to the bottom of the vessel in which the operation is performed. Frozen potatoes may be profitably employed in this way, if grated before they thaw, they are found to yield half as much starch as fresh or unfrozen ones. The refuse pulp, when taken from the sieve, possesses the property of cleansing woollen cloths without hurting their colors; and the water decanted from starch powder is excellent for cleansing silks, without the smallest injury to their color.

We have said that the constituents of sugar and starch are the same, though differing in their proportions. The component parts of each, in 100, are given in Davy's Agricultural Chemistry as follows:

		Sugar.		Starch.
Carbon,	(Lavoissier,) .	28	(Thenard,)	43.55
Oxygen, .	" ..	64	"	49.68
Hydrogen,	" ..	8—100	"	6.77—100
Or, Carbon,	(Thenard,)	42.47	"	43.55
Of water or its elements,	"	57.53—100	"	56.45—100

We have also stated, in the 12th number of our first volume, on the authority of the Edinburgh Quarterly Journal of Agriculture, that starch may be converted into sugar, by means of sulphuric acid, &c. Our correspondent wishes to know the quantity of acid employed, and the whole process of transmutation. Upon these points we cannot enlighten him or the public farther than we have already published; and we do not know that the process has yet been promulgated.

To raise carrot seed, Mr. E. is informed, it is not necessary to use either long or short manure, if the soil is rich, as it ought to be. Plant out the roots in the last of April, or first of May, three feet apart, and drive a stake down by each plant; and as the seed stalks rise, tie them to the stakes, and gather the seed as it ripens.

Devastation by Blackbirds.—O. H. Otis writes us from Bristol, Wisconsin, that the times have proved disastrous there, to new settlers, on account of the ravenous birds, which destroyed the crops of the last season almost entirely, with the exception of potatoes. He implores our advice, how to diminish the unaccountable number of blackbirds that visit them during the harvest season; and we are sorry that it is not in our power to offer him relief.

"*Interior*," who dates at Little-Falls, admonishes against the use of tobacco water, in destroying lice upon cattle; and states, that where it has been used, some have sickened and died. He quotes Prof. Muzzy on the poisonous quality of the *oil* of tobacco, in support of his hypothesis. There is a manifest difference between the decoction and the oil; and as immence numbers of cattle and sheep have been washed with the former, or immersed in it, without it having caused sickness and death, we suspect that in the fatal cases noted by our correspondent, the calamity would have befallen the animals, even if the decoction had not been applied.

Another anonymous correspondent, who dates from Masonville, advises that calves tails be shortened some eight or ten inches, in order to prevent the "horn-ail," when they become of age! We cannot become a party in the outrage against the works of Providence which this practice would inflict; and therefore protest against the preventive, as contrary to reason as well as humanity. To atone for this, however, our correspondent recommends improvements in feeding hay and constructing milk-houses, which are better entitled to notice. In the first he recommends a free use of the hay knife, that the fodder may be taken from a small, rather than a large surface—the former being more snug, economical, and less injurious to the hay than the latter. He has his milk-house raised above the surface of the ground, instead of its being sunk below it, as in a cellar or spring house, with a trap-door in the floor, for the purpose of letting in fresh air from below. He has windows, with shutters which are closed in a hot day, and his house is shaded by surrounding trees. He thinks he gets more cream in this way than in any other, as his milk-room is generally cool and dry. The suggestions are worthy the notice of dairymen.

After culture.—G. W. Latham, of Jeffersonton, Va. wishes us to explain what we mean by "*after culture*," as applied to the corn crop. We mean all the culture that is given to the crop *after the seed is deposited in the ground.*

Miller's Toll.—A correspondent in Owego, wishes to know what toll millers have a right to take by law for grinding grain. The communication of our correspondent would be given entire but for the press of other matter. Our correspondent weighed all the grain he had ground, for some months, took it to mill himself, and afterwards weighed the product. The result was, he found that *twenty* per cent had been abstracted for toll, instead of ten per cent, which he supposed was the legal allowance. Assuming that our population is two millions, and that each inhabitant consumes five bushels annually, the difference between ten and twenty per cent toll, gives an aggregate to the millers of *one million of bushels* of grain annually, more than he thinks they are entitled to. We confess our surprise at not finding any law regulating this matter, and on being told that there was no such law. We have weighed our grain also, and have found the same result—a diminution of twenty and twenty-two per cent abstracted for toll. These impositions are so gross as to call for legislative enactments on the subject. As long as the matter is left to the discretion of the miller, impositions will continue. It is at all events proper, that the miller should be required to put up a notice on his door, of the rate of toll he does take, and to be obliged to abide by his rule, that his customers may be apprised of the fact, and be enabled thereby to select the most reasonable. At present, custom, which, in the absence of law, has the binding force of law, seems to have settled the toll at ten per cent. If the miller can with impunity take twenty, he may by the same rule take fifty per cent. The business really requires to be regulated by some definitive and binding regulations.

Spent Tan Bark.—A correspondent, who dates from West Haverford—asks us some puzzling questions about tan as a manure, and the chemical combinations which take place on its being mixed with caustic lime. We can only answer, in general terms, that tan is among the most stubborn materials to render soluble in the vegetable kingdom, and that until it is rendered soluble, it imparts no fertility, but rather abstracts from it. It is doubtful whether lime will so decompose it as to render it fertilizing; as Sir Humphrey Davy lays it down, that it must undergo fermentation to render it nutritive, and that like peat earth, it will not ferment "unless some substances are mixed with it which act the same part as the mucilage, sugar, and extractive or albumenous matters with which it is usually associated in herbs and succulent vegetables." Hence we should try fresh stable dung, instead of lime, to effect a fermentation, or the decomposition of tan.

Ed. Carpenter, of Glassborough, having come into the possession of a worn-out farm, a year ago, has detailed to us his practice the last summer, and asked our advice as to the best means of improvting it. Mr. C. has began well, in gathering fertilizing matters, and in raising ruta baga—(at the rate of 600 bushels to the acre,) and in feeding these to his stock. All farm stock may be kept entirely on these roots, if desired, with the addition of straw. If Mr. C.'s land will bear clover, the seed of this may be profitably sown with every small grain crop; and, until he has succeeded in restoring fertility, no field should be cropped more than two, or at farthest three seasons, before it is again stocked with clover and other grass seeds. Marl, if good, may be profitably transported four miles to improve his land. If Mr. C. will carefully save and apply all the manure he can gather,—dress his land with marl,—alternate his crops—and stick to clover and roots, with industry and good management—he will renovate the fertility of his soil, and prosper, in despite of the laugh of his neighbors. And we beg to be advised of the fulfilment of our prediction.

Experiments in feeding roots.—W. Catton, of Lenox, N. Y. writes us, that he has gone to some extent in the culture of roots; that he has made several experiments in feeding them to stock; and that he finds carrots and sugar beets to be the most profitable for fattening cattle, and the ruta baga for milch cows and sheep. He raised the sugar beet at the rate of 1,000 bushels to the acre, and thinks them preferable to the mangold wurtzel.

Fred. Seitz, of Easton, Pa. having prepared a piece of ground, a sward, last fall, for ruta baga, asks if he can manure and crop it in the spring, with tares or other vegetables, in time to sow ruta baga. He might have sown it with rye, in the fall, upon the ley, to be fed off in the spring, and he may yet do it early in the spring, covering with the harrow—putting two bushels of seed to the acre. He can put on no crop that will mature in time. Tares, we believe, are not to be had in the country. Let the manure be reserved for the turnips, and the seed be drilled or sown upon the fresh turned soil.

Tea wheat, Mr. Edgerton assures us, produces from twenty to thirty bushels per acre in Wallingford, and is sown there from 15th to 20th May.

Ruta baga in Pennsylvania.—S. Mayleet, who dates at Montrose, Susquehannah county, assures us that he raised last year, 1,100 bushels ruta baga upon 132 perches land, equal to 1,333 1-3 bushels on the acre. Mr. M. boiled the roots, and fattened his hogs upon them, with the addition of coarse grain provender, and his pork, he says, is excellent. The root were grown in drills two feet apart, with intervals of ten inches between the plants—beech and maple soil, highly manured. We are glad to learn that this culture is extending. Ten thousand bushels, our correspondent advises us, were raised last year in his county, and 2,000 by one individual.

Steeping seed wheat to prevent rust.—Among other interesting facts communicated by Walter Scott, of Bovina, Del. county, in regard to farming, he states that two years ago, he dissolved a quart of salt in a gallon of water, boiled the pickle, and when sufficiently cooled, mixed it with his seed wheat in a tub, and sowed it. The crop was good, and was affected by neither smut nor rust. Some ears were selected when harvesting the grain, and sown in the garden last year, without being steeped; while some bushels were sown in the field, after having been pickled as before. The grain sown in the garden, was destroyed by rust; while that in the field escaped unhurt. The inference we are left to make is, that the salt prevented the rust, though we by no means consider the fact established. The probability seems rather, that the wheat in the garden was destroyed by rust, not because it had not been steeped, but because the garden had been made too rich, with long dung. The experiment is, however, worth repeating.

Several communications on hand will be published or noticed in our next.

Acknowledgements.—Texian corn from S. Carolina and from Harrisburgh; a sample of twelve-rowed yellow corn from S. W. Jewett, Weybridge, Vt. said to be very early; seeds of Prairie flowers, from G. W. Lee, Marion county, Mich.; Egyptian wheat, from several gentlemen—(see our remarks upon this grain;) a sample of beautiful spring wheat from J. G. Soulard, Galena, brought from Lord Selkirk's settlements on North Red River, lat. 50. This promises to be a valuable acquisition to our husbandry—(see Mr. Soulard's letter, under correspondence;) tea wheat from S. M. Edgerton, Wallingford, Vt. a beautiful sample, for sale by Thorburn; giant wheat from W. Thorburn.

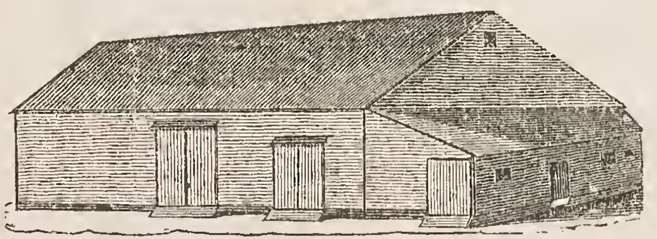
☞ We shall take the liberty of forwarding this number to several gentlemen, as a sample of our work. Should it meet their approbation, we shall be happy to continue to them the subsequent numbers of the volume.

CORRESPONDENCE.

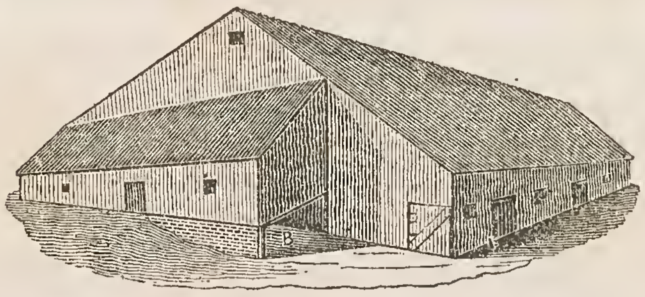
Plan for a Barn.

J. Buel,—Dear Sir,—I send you my plan for a barn, not because I think it perfect; but because I think it better adapted to the *means* and *wants* of common farmers than any I have yet seen published. I would prefer ground sloping to the south on east, about one foot in six or seven, for the convenience of digging out the basement, which in this plan is the full size of the upright part of the barn and the stable across the end, or thirty feet by fifty-eight, and walled on three sides. Having in prospect the rapid extension of root culture among us, I consider a cellar as necessary to the barn as to the farm house. A sufficient share of the basement should, therefore, be partitioned off from the rest, by double partitions, filled with chaff or tan-bark, to prevent frost. The remainder of the basement is to be used as a shelter for sheep or cattle, or a portion may be appropriated (as in the following plan) for a walk and the gearing of a horse power. I send two rough views and a ground plan. Figure 4 shows the upperhill side of the barn, the ridge of which, if the ground on which it is built slopes to the east, will run north and south. The upright part is forty-six feet by thirty, with a lean-to stable twelve feet by thirty. This stable has the first portion of it divided into stalls for horses, and the remainder for oxen. This side of the barn stands eighteen inches from the ground, and the cellar is lighted by double glazed windows beneath the sills. Figure 5 shows an oblique view of the west end and lower-hill side of the same barn, with a stable running the whole length of the upright part of it, that is, forty-six feet long. This stable is also twelve feet wide, and the floor of it is on the same level with the bottom of the basement; it has a manger the whole length of it, next the upright part of the barn, into which hay may be thrown from the barn floor, or roots may be carried from the cellar through a door, shown in the ground plan. This figure also shows the opening, B, twelve feet wide and seven feet high to the basement, sufficient to drive in a cart to clean out the manure. Figure 6 is the ground plan; 1, bay twelve feet by thirty; 2, barn floor, eighteen by thirty, barn doors twelve feet wide; 3, wagon house sixteen by twenty, with doors at *b*, nine feet wide; another at 4, into the horse stable; 5, tool room ten feet by sixteen. A scaffold extends over this and the wagon house, to be filled with hay fed through an aperture at the west end of the barn, into the manger *m*, or thrown to the cutting box on the barn floor. The dotted line shows the partition which stands two feet under the barn floor, making the cellar twenty feet by thirty. At this side of the barn floor is a narrow trap door *f*, down which roots may be emptied. The larger dotted circle shows the walk for horse power beneath the barn floor; *d*, is a cellar separated from the inner one ten feet by twenty, with a door at *g*; *h* is a well, furnished with a pump. Here also should stand a vat, large enough to hold a foddering for the stock. A vegetable cutter, driven by a band from the horse power, should likewise be placed here. Over that part of this cellar, which projects beneath the barn floor, should stand a straw cutter, and a small corn-cracker, (driven by the same power,) with tubes made of boards leading into the vat below. There is also a stairway leading down into this cellar at the extreme end of the barn floor *S*. It will be seen by this arrangement of these labor-saving machines, that corn in the ear, or other coarse grain, may be cracked, and roots cut, by being previously placed in their respective hoppers, by the same operation of the horse, and by the same hand while he is feeding the straw-cutter, and all deposited in the vat below. Here, after moistening with water and stirring together, it is carried through the door *i*, and fed along the manger of the long stable, shown in figure 4, or carried out the north end of the same stable, and fed along the row of sheds that form the inclosure of the north side of the yard.

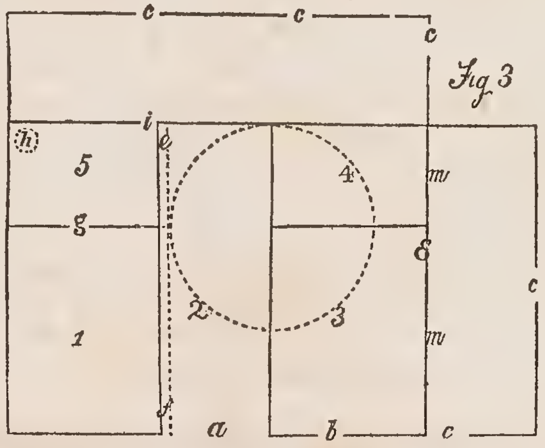
[Fig. No. 4.]



[Fig. No. 5.]

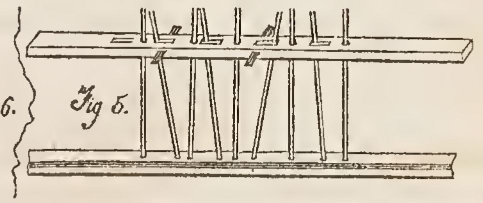


[Fig. No. 6.]

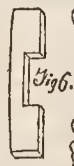


I prefer the *Yankee* mode of fastening cows, or other cattle, called stantials, a section of which is shown in figure 7, on account of cheapness, durability, security, facility of fastening and economy of room, two feet ten inches being sufficient for cows, and three feet for oxen. Figure 8 shows the fastening key.

[Fig. No. 7.]



[Fig. No. 8.]



A lean to shed may also be built against the north end of the barn, to be used as a shelter for carts, ploughs, &c. which will give the barn a good appearance.

This plan may easily be adapted to level ground, only the basement must be dispensed with, the floors all on the same level, the roots brought up from the cellar below, the horse power in an adjoining shed, unless it is on the endless chain principle, which may be set in the floored recess, denominated tool room, 5, shown in the ground plan. The upright part of the barn is framed as though there were no stables attached. The stables are all lean-tos of the most simple structure, though well covered and ventilated by windows.

Yours, L. B. ARMSTRONG.

Kingsbury, Jan. 1st, 1838.

Advantages of Agricultural Journals.

Sir,—I fear that the trifling sum of fifty cents, added to the price of the Cultivator, will curtail its usefulness, by inducing many to withhold their patronage; and consequently put a damper on their further improvement. Such a view of the subject has induced me to trouble you with this communication, hoping, that a statement of some of the advantages which I have derived from its perusal, may induce others to continue their subscription. Not having been bred a farmer, I was, of course, in a measure ignorant of the practice and theory when I commenced farming, eleven years ago. I then took some pains to inform myself of the most approved methods of managing, many of which I have since found to be (unaided as they were by the light of science,) materially wrong, and some, in fact, exactly the reverse from what they should be, both in theory and practice. For proof, I adduce the practice of applying manure. It was then thought the older the manure the better, and of course they did not apply it to their land, till it was eight months or one year old; and then its application to meadow land was thought to be the most profitable. If applied to tilled land, the practice of many was to spread it on the surface, alleging as a reason, that the juices must progress downward, and if buried with the plough, must be lost in a great measure to the roots of the grain. So in securing the corn crop, it was supposed the corn must be topped, to have the grain ripen well; and I am sorry the practice still prevails with so many. Evidences of its absurdity were not wanting last fall in this section of the country. So with seeding land; two quarts of clover, and two quarts of grass seed, were then considered sufficient for an acre; now four of each is little enough; and the difference is, instead of johnswort, daises, and other pernicious weeds, our land is covered with clover and herdsgrass, and any field may be a meadow.

The culture of roots I consider a great acquisition to the produce of a farm, (not so much in the bare nominal value of the roots, as in the improvement of stock and the consequent larger production of meat, butter, and wool,) as it has enabled me to make more butter from one cow, than I formerly made from two fed in the usual way. Two hundred and seventy-two and a half pounds of butter, I have made from one cow the last season, besides supplying a family of six persons with plenty of milk. All that is extra in the above yield, I attribute to feeding roots, which I do freely through the winter and spring months; consequently my cow is in high flesh at all seasons of the year.

Cutting feed for horses or cattle I consider very profitable, having kept a pair of horses mostly for two winters on oats in the bundle, cutting four bundles a day for the pair, which keeps them in fine condition without hay. They are kept in this way ninety-four days, from the produce of one acre, yielding fifty bushels, which at the present price of oats, would cost twenty dollars. In the ordinary way of keeping horses, the same length of time, and to keep them in as good condition, they will require two tons of hay, worth sixteen dollars, and six quarts of oats a piece per day, making thirty-five bushels, worth fourteen dollars; amounting in all to thirty dollars; leaving a saving in favor of cut feed, of ten dollars for about three months, or twenty dollars for six months, or for the usual time of keeping horses in the stable, which is about eight months, of thirty-three dollars—sufficient to pay for one of Green's Straw Cutters, or the hire of a man for four months in the winter season. The result of the above estimate will be about the same with straw and provender.

The above are but few of the items of profit which I have derived from improvements made in farming within the last four years; but I forbear to speak of the advantages of draining land, curing hay, rotation of crops, fattening hogs, destruction of Canada thistles and other noxious weeds; improvements in gardening, straw cutter, cultivator, horse rake, drill barrow, and economy in the kitchen, which must be mostly attributed to the dissemination of useful knowledge, through the medium of agricultural publications; and had I possessed the same sources of information seven years sooner, the actual profit arising from it, could not have been less than one thousand dollars. Who then would be deprived of the benefit of what I have enumerated for one dollar a year? Who would be deprived of the reflection of having done something to improve his condition, and that of his posterity, for that paltry sum? Who would rather plod along in the footsteps of their forefathers, without the gratifying reflection of having improved their condition? Enlightened minds dwell with pleasure on the advances they make in any object worthy of their attention, whether in reference to the improvement of their time, or to the condition of their farms, or stock, or the liquidation of debts, or the enlargement of estates; some such stimulus is necessary to satisfy the man of business, otherwise he would seem to have lived in vain; for if, in the retrospect, he can find nothing to gratify, or cheer the mind, it will put a damper on future exertions, and leave no encouragement for improvement hereafter; and all the time thus spent, is lost to the gratification of the finer feelings, and leaves but the unwelcome reflection, that another year of his life is spent to no good purpose. Improvement should be the main-spring of all our exertions, and all means within our reach to obtain information in reference to our business, should be employed; reflection, close observation, and the careful perusal of some publication devoted to agriculture, combining the observation and experiments of men of science, as well as of common practical farmers, are within the reach of all, and should be sought after.

Yours, &c.

To J. Buel, Esq. DANIEL S. CURTIS.

Canaan Centre, February 12th, 1838.

Plan for a set of Buildings for a Farm, &c.

Mr. Buel,—I respectfully submit for your consideration, and herewith send you drawings of a plan, for a set of buildings, suitable for a farm of an hundred and fifty to two hundred acres, where breeding neat stock, dairy or growing of wool, forms the principal part of the business.

In such a cold and variable climate as we live in, I consider it of very great importance that all animals, under our charge, should not only be *well fed*, but *comfortably* housed.

Where is the person that has travelled through the country in the winter, and has not noticed a lot of half starved animals, standing on the south side of a barn, with their backs drawn up, and their feet in the compass of an half bushel; and in some places not even a wall or fence to shelter them from the pelting storm, or a piercing north-wester, without even straw or any other litter to protect them from the severity of the season. And it is not unfrequent to see them standing around a stack of hay, on the top or side of an hill, without any other protection than that afforded by the stack. Where is the person, I repeat, that has observed the above, without emotions of regret, that there is *one so destitute of feeling* to the beasts which form so great a share of our comfort and wealth?

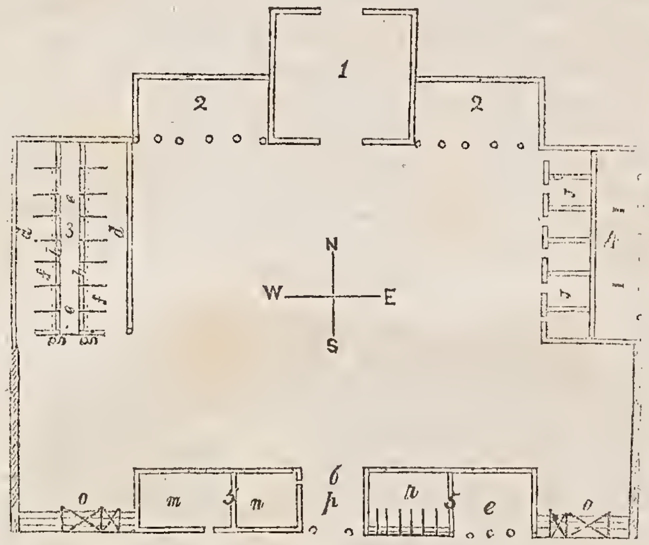
Now, it is not expected that every farmer can afford, however willing, costly stables and sheds for his stock; but it is in the power of most of them, to erect sheds or hovels made of poles and pine or hemlock boughs, with a little straw or coarse grass for a covering, which would, in a degree, protect them from the winds and storms of winter.

And where is the person, that has visited a well conducted establishment—where the cattle are not only housed, but well littered and kept perfectly clean —the hair laid perfectly smooth every day with the card—their full bodies, sleek sides, and placid countenances evincing *good care* and *good keep*?

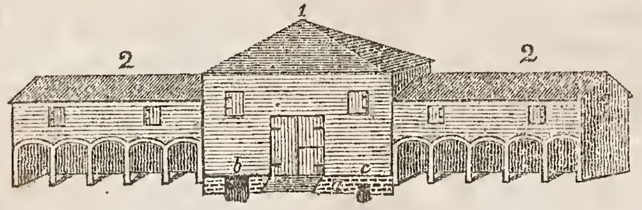
Where is the person who has witnessed the above, and not felt a degree of satisfaction to know that there are *some* who are not regardless of the comfort of the brutes who are by Providence confided to our care and protection?

But to return to my plan. The area for the yard [See figure 9] should be 120 feet square; in the centre of the north line of the yard, is to be a barn, (No. 10,) forty feet square, and twenty feet posts; to be raised from the surface of the yard, by a stone wall (a) foundation, laid in mortar, two feet above the ground, with a cellar seven feet deep, for vegetables. A door (b) and passage for a cart to pass through, for the purpose of putting in and taking out roots; and a window (c) on each side to serve as ventilators. The doors of the barn to be twelve feet wide and twelve feet high, and the floor fourteen feet wide.

[Ground Plan, Fig. No. 9.]



[North Section, Fig. No. 10.]



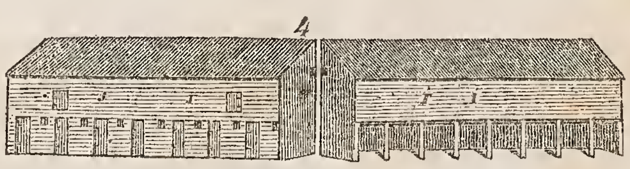
On each side of the barn are to be sheds (2, 2,) 40 by 20 ft. and fifteen feet posts. The lower part to be open sheds, six ft. high, and the upper story for storing hay or grain.

[West Section, Fig. No. 11.]

No. 11, is a building to be placed on the west line of the yard, for a cattle stable, sixty feet long, thirty-two ft. wide, and fifteen ft. posts. The stables, (d, d,) on the ground plan, to be seven ft. between the floors; a passage (e,) of four feet, running lengthways through the centre, which will give eight stalls (f, f,) on each side, of seven feet each, suitable for two animals in a stall, to be secured by chains or bows to stancheons (g, g,) by the side of the partitions. Mangers, (h, h.) to be one foot six inches deep and two feet wide. Doors or windows on each side for ventilation and throwing out the manure; but I would recommend to have the manure scattered in the yard, by means of a wheel barrow. The upper story, or loft, for storing hay, with a space, in the centre, say eight by ten feet, for a straw cutter, with a hole in the floor, 18 inches square, and a tube to conduct the cut hay to the passage, from whence it is to be fed.

No. 12 is the building designed to be placed on the east line of the yard, sixty by twenty-five feet, fifteen feet posts; the east side (i, i,) of this building, as seen in the view, is intended for sheep sheds, twelve feet in width and six feet high, running the whole length of the building, to be divided into as many apartments as may be deemed necessary for the different classes of sheep.

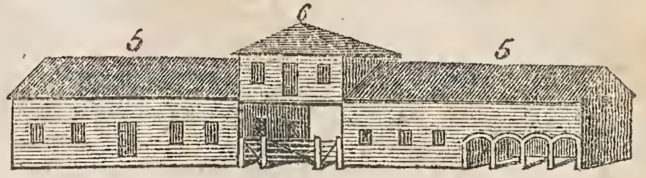
[East Section Fig. No. 12.]



In the west side of the same building, fronting the yard, see also west front, (j, j,) are to be six stables for cows to calve in. These will also be convenient for ewes and lambs when necessary to be housed.

No. 13, 13, forming the south side of the yard, are two buildings, fifty feet long, twenty feet wide, and fourteen feet posts, with a passage of twenty feet, over which is a building, (5, 5,) twenty feet square, twelve feet from the ground, twenty feet posts. This building is intended for storing coarse feed, &c. &c. having a tackle for the purpose of hoisting up the grain. In the east wing (k) is a stable for six horses, and room for harness, &c. The stable to be twenty-five feet long, and twenty wide. In the stable, near the door, may be placed a bin for horse feed, which may be conducted by means of a tube, from the granary above. The remainder of this wing (l,) is designed for sheds for housing wagons, carts, sleds, and other bulky implements.

[South Section, Fig. Nos. 13, 13.]

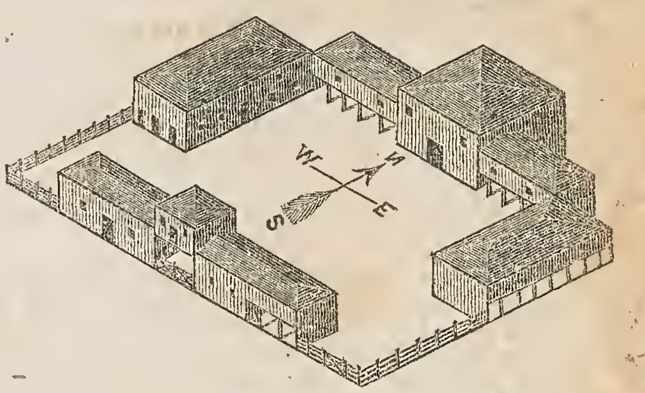


The lower part of the west wing (m,) is for storing farm implements, and (n,) a work shop—The lofts of both wings for storing hay or straw.

Now, as the east and west buildings are only sixty feet long, there will be sixty feet of fence to reach the line of the south buildings, indicated by dotted lines. Should the entrance to the cattle stables be in the south end, as laid down in the plan, No. 11, it will be necessary to start the fence from the extreme west side, which makes the yard thirty-two feet wider, and to correspond and for appearance, I would start the fence on the other side of the yard, from the extreme east side of No. 12, which will make the yard still twenty-five feet wider. This will give room, on each end of the south range for gates, as at (o, o.)

I would recommend a good hard road to be made from the passage (p,) to the barn No. 9, and on each side of this road I would have the yard excavated or hollowed, sloping to the centre, and over these excavations may be erected sheds to protect the manure from evaporation. [See perspective view.]

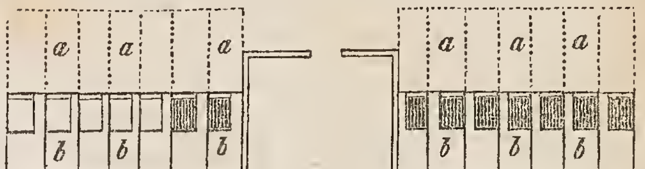
[Perspective View, Fig. No. 14.]



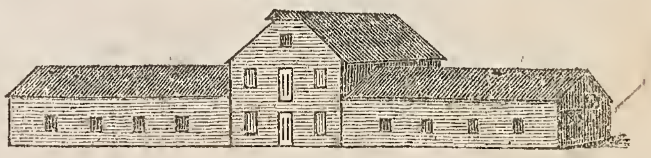
The yard may be divided for different grades of cattle, and running water should, if possible, be introduced into each yard.

I will also give you a plan of my piggery, (15, 16;)

[Ground plan of Piggery, Fig. No. 15.]



[Elevation of Piggery, Fig. No. 16.]



It forms the south side of my barn yard. The centre building is two stories high, twenty-five feet long, and twenty feet wide, fourteen feet posts, with a cellar underneath for roots. The first story is intended for boiling or steaming food for the hogs. The second story is my store room for coarse grain, &c. &c. On each side are wings extending fifty feet from the centre building, eighteen feet wide and eight feet posts. Each of these wings are divided into seven apartments, (b, b, b, b, b, b,) nine of which are for breeding sows, with a sleeping room to each; one for a boar and four for fattening or store hogs. There is a passage (c, c,) leading from the centre building, in front of the pens, four feet wide, in which project the feeding troughs, one foot wide, extending the whole length, with doors similar to the Shaker plan, as described in Vol. 2, No. 7, of the Cultivator. The troughs are divided, one-third for the sow, and the remainder for the pigs, and is so contrived, by means of the studs standing so near together that the mother cannot rob the pigs of their food. A hog is a *hog*, put him where you will.

In the rear of each of these pens are yards, (a, a, a, a,) seven feet wide and sixteen feet long, with sliding doors in the partitions, and a door communicating with the barn yard from each of the outside yards. These yards are for exercise, air, and for the manure. Into these yards I cause to be thrown weeds, sods, muck, potato tops, and all refuse straw I can get; and now and then a load of fresh manure from the horse stables; and should the hogs not work sufficiently, by throwing in a small quantity of corn or oats, they will set to work most lustily and turn it over faithfully.

From my pig yards I took, last year, over eighty loads of first rate manure, which is worth, at least, one dollar per load. This will nearly pay for a man to take care of them.

Should the above plans be on too large a scale, they may be so modified and arranged as to suit any sized farm. C. N. BEMENT.

Profits of the Dairy.

Rensselaerville, Jan. 31, 1838.

Jesse Buel,—Sir,—Below is a statement of the amount of butter and cheese made from my dairy of six cows in eight months of last season, which I think will do credit to the farming and dairy interest in this town.

1448 lbs. cheese, which sold at my door at 7¼ cts.	$104 88
452 lbs. cheese at 8 cts.	36 16
415 " butter at 18 cts.	77 85
	$218 89

Making an average of $36.48 1-6 per each cow. Sir, will you please give the above an insertion in your valuable Cultivator? and you will much oblige yours, &c. REV. EPHRAIM CROCKER.

Culture of Indian Corn, &c.

Troy, Jan'y. 26*th*, 1838.

Judge Buel,—Dear Sir,—Having purchased a farm about two years ago in this vicinity, and concluding to direct its cultivation myself the past season, and being without practical knowledge in agricultural pursuits, I sought through the columns of the Cultivator the information I needed, and without which I could not expect to be successful in this new, and, to me, interesting enterprise. Having concluded to plant about nine acres with corn, I examined with some minuteness the different modes recommended for its culture. After this examination, believing I discovered substantial reasons, combined with practical knowledge, in your manner of cultivating this crop, I was not long in deciding on adopting it. And now, not that the yield was an extraordinary one, but because it was much better than others in this vicinity where the old mode had been adhered to, and because by adding further testimony to yours, it may be the means of inducing others to test its utility—although you have so repeatedly recommended this mode of culture, it may not be amiss to state in some detail the course pursued in the culture of this crop.

The land planted may be denominated a dry gravelly soil. About four acres of which had the preceding year been in buckwheat, and the remaining five acres in pasture for several years; the latter I had ploughed late in the preceding fall, to prevent the ravages of the grub worm; during the winter and spring I deposited in small piles on the two pieces, about 280 wagon and sleigh loads of manure, more than 200 loads of which was from a neighboring slaughtering house, the remainder was unfermented barn-yard manure; it was evenly spread on the surface and ploughed under just before planting. The ground was furrowed about three feet apart each way, and planted in hills the same distance apart, putting in each hill six to eight kernels. Commenced planting on the eleventh, and finished on the nineteenth May. The varieties planted were your twelve-rowed Dutton, the small and the large eight-rowed yellow, and a flesh colored corn. The Dutton was planted on the 17th May. This is stated, as the result will show its early maturity. The corn was not sufficiently thinned, as from five to seven stalks were left in some hills, three or four would have been more profitable. A plough was not used after it was furrowed. The crop had two dressings with the cultivator and hoe; plaster was applied as usual, and pulverized bones were put in a few rows when planted, and to some extent used with the plaster on the hills. I prefer this article to plaster, as its effects were visible where used. The corn was slightly hilled, formed broad and flat, to retain the surface of the ground as even as possible. The corn came up well, and maintained through the season a healthy appearance and a vigorous growth. On the 6th of September much of the corn was ripe, and the remainder well glazed; on this day commenced cutting it up at the surface of the ground, and put twenty hills in a stook to cure; on the 19th September, it being well cured, commenced husking it in the field, from the stooks, separating the nubins from the larger ears. On the 6th October this process was completed, with the exception of a small quantity put in the barn. The result was as follows:

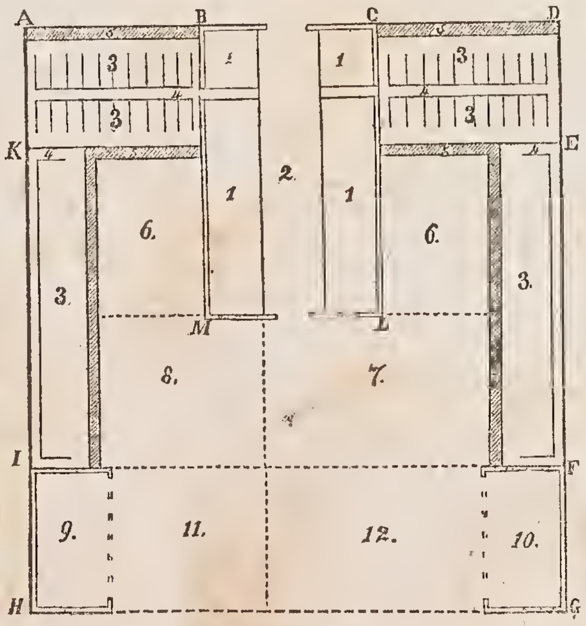
956 bushels ears of corn, which I put down at 4*s*.		$478 00
About 38 loads of pumpkins, 12*s*.		57 00
About 27 loads corn stocks well cured, 16*s*.		54 00
		$589 00
Expense of cultivating the crop, except drawing in pumpkins and stalks,	$162 42	
Interest on 9 acres of land, at $100 per acre,	63 00	
		225 42
Nett profit,		$363 58

As I do not reside on the farm and pay cash for labor, it has enabled me to keep a pretty correct account of the expenses of this crop. I may have overrated its value, though I have sold about 145 bushels shelled corn, at 8*s*. a bushel, and as the corn is sound and bright, considerable will sell for seed at an advance from this price, though some allowance should be made for shrinkage. I consider the stocks for fodder worth the estimate. They are used for principal fodder for eight head of cattle, and it is now mid winter, and not near half have been fed out. I have not charged the manure, as I deem its value to the land in succeeding crops ample to cover cost. Taking the footing of the above as a basis, it will exhibit a profit of about forty-seven per cent on the capital so far as the land is concerned.

Although I may trespass upon your columns, I beg to make another remark: that is, surprise I have felt at the apathy exhibited by the agricultural interest of this state, in not presenting and enforcing its just claims on the legislature, for its encouragement and its bounty. What branch of industry has not done this? and what can present so well grounded claims? What has done so much to elevate the state to its present power, wealth and resources? And yet its claims have been comparatively disregarded. Permit me to suggest the idea, that the State Agricultural Society at the approaching meeting, appoint a committee of ten or more efficient individuals in each country in the state, or the supervisors of the several towns in the state, whose duty it shall be to cause petitions to be circulated for signatures in each town, setting forth the claims of this branch of industry, and cause them to be presented to the next legislature for their action. This done, and no one can reasonably doubt its effect, as this interest holds the controlling influence; and it needs only to be aroused to concentrated action, and its influence will be felt in the councils of the state, and its just claims will no longer be disregarded. A SUBSCRIBER.

Judge Buel,—Dear Sir,—Enclosed I send you a rough ground plan for a barn, the situation of which would be on the east bank of the Niagara river, nearly a level plain, and consequently much exposed to the cold northern and western winds; in planning it, therefore, one great object has been to obtain *well sheltered yards*, the expression of the architecture being a matter of mere fancy. I have an old affair with rough sheds in miniature of the above, but as I hope it may soon give place to a new one, which I should wish as perfect as possible, I should be very much obliged by any criticisms, or suggestions of improvement from your good self, or correspondents, in regard to it. I will now proceed to explanatory details.

[Ground Plan, Fig. No. 17.]

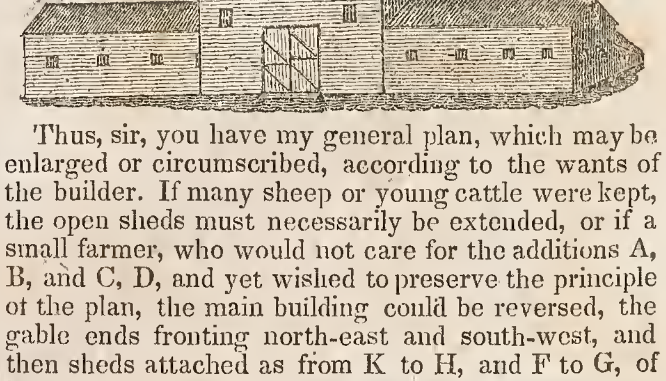


B, C, L, M, (fig. 17,) is the main part of the building, sixty feet by one hundred, with the gable ends fronting south-east and north-west; the sills laid upon a wall three feet high, open, however, on the south-east end into the yard, where hogs could be kept, or terrier dogs have free ingress, and thus destroy rats or any vermin that might be disposed to harbor under the bays. A mast also should be placed in the centre of each mow, leaving a space around it, in the manner of the Shaker's barn at Hancock, for the purpose of ventilation, and carrying off the steam from the new hay, and the open space under the bays would be necessary to insure a sufficient current of air for this purpose. Under the passage way the earth should be excavated four feet, and a strong cemented wall built up to the floor, thus making a cellar seven feet deep, one hundred feet long, and twenty feet wide, and capable of holding more than 8,000 bushels of roots, and perfectly rat proof. In the floor, over the cellar, trap doors should be placed sufficiently often, so that carts loaded with roots might drive in and be tipped up, thus saving the whole labor of unloading, that is usual in carrying into cellars. A moveable tackle and fall should be hung, with large baskets, so that one man could hoist out any quantity of roots through the trap doors when wanted. For the bays a crane should be rigged, that would take up the hay loaded on the carts, in a moveable rack-body from the wheels, swinging it over the mow, and then turning it topsy-turvy, and thus unload in a single minute. Granaries could be partitioned off from any part of the bays with hemlock plank, through which a rat never knaws, and any other internal arrangements made that fancy or convenience required. Many would undoubtedly object to so wide a passage as twenty feet in the main building, but I find a roomy thoroughfare and threshing floor of very great convenience for a thousand purposes of the barn and stock, and besides, if not all were thus wanted, any part could be used just as well as if it were so much bay, in the storage of grain, in sheaf, corn in stook, &c. &c.

A, B, and C, D, would be additions running out sixty feet each side of the main building, B, C, L, M, with gable ends fronting north-east and south-west, and may be built sufficiently high to accommodate all the hay over head that the cattle stabled in them would consume during winter, or their fodder could be thrown from the bays, and taken through the five feet passage ways to their mangers. Plank or ground floors, as is judged best, could be used, the bottom of the stercorary sunk three feet below, with a cement floor, and laid up in wall, the roof running over it, and doorway partitions between it and the stable, to be opened only when the stables were cleaning. The manure thus, both solid and liquid, would be completely protected from wasting air and rains, and its whole nutriment preserved till the moment of its being carted out to fertilize the land. Two feet of turf placed on the bottom of the stercoraries in the fall of the year, and laying all winter with the urine from the stables, and moisture of the cleanings leaking down and saturating it, would become in the spring, for most purposes, equally valuable to fresh dropped stable manure.

K, I, H, and E, F, G, are sheds running south-east from the additions A, B, and C, D, and parallel to the main building. These also could be of a sufficient height to take in fodder enough over head for support of the stock below through the winter. The stables, &c. are on the same plan of A, B, and C, D, and need no further remark. From I to H, and F to G, are left as open sheds, either for sheep and young cattle, or tool and wagon house. A well should be sunk, and a pump house erected over it, where the four corners of the large yards meet, with watering troughs in each, and pipes leading to them, and so arranged that the water would not freeze in them during the coldest weather. The yard fences may be so constructed as to be enlarged or contracted at pleasure, or more subdivisions made if necessary. The divisions seem to me of great utility and convenience. Sheep may be thus kept separated, large and small cattle divided, breeding mares, colts, and stud horses let out from their box stalls, for the regular exercise, that is so beneficial to them in winter, and for want of which disease is often contracted.

[North View, Fig. No. 18.]



Thus, sir, you have my general plan, which may be enlarged or circumscribed, according to the wants of the builder. If many sheep or young cattle were kept, the open sheds must necessarily be extended, or if a small farmer, who would not care for the additions A, B, and C, D, and yet wished to preserve the principle of the plan, the main building could be reversed, the gable ends fronting north-east and south-west, and then sheds attached as from K to H, and F to G, of just such dimensions as suited his wants.

I consider all stock buildings as *radically* deficient in comfort and convenience, that do not shelter from the cold winds, that so completely desolate the northern part of the American continent during winter, and yet how seldom do we find that this matter is *even thought of*. I know not a barn thus protected in this whole region. Had stock growers the least consideration for the well being of their poor dumb animals, or regard for their own interests, they would in every instance immediately erect wind and rain shelters for their cattle; and however rude at first they might be, the gain in growth and economy in feed they would find to be greatly increased, much more so than those can have the least idea, who have not yet made the experiment. Very respectfully yours,

LA GRANGE.

Explanation of the Cuts.

Fig. 17, presents a ground plan; Fig. 18, is a north-west view of the barn and stables; 1, 1, are bays, 20 feet broad; 2, main passage, threshing floor, &c. 20 feet wide; 3, 3, 3, 3, stables, 14 feet wide; 4, 4, 4, 4, passage ways, 5 feet; 5, 5, 5, 5, stercoraries, 7, feet; 6, 6, yards, 34 by 53; 7, yard, 30 by 74; 8, yard, 50 by 54; 9, 10, open sheds for cattle, sheep, wagons, &c.; 11, yard, 50 by 75; 12, yard, 50 by 100.

Objections to Live Fences.

Essex co. Virginia, Jan. 17th, 1838.

DEAR SIR,—Your truly valuable paper is taken by my oldest son, and I always read it with great interest, although it occasionally contains articles on which I feel strongly inclined to comment, but have doubted whether you would not constantly have on hand numerous other communications better worth publishing than any thing I could send you. The spirit, however, moveth me so, at present, that I venture to offer you some remarks on the subject of live hedges, in opposition to the views expressed by yourself and others, in your January number.

I assume it as a proposition susceptible almost of perfect demonstration, that live hedges cannot be advantageously adopted, in our country, as a general system of inclosure. First, because they are actually more expensive, in most situations, than dead fences. Secondly, because there are no plants or trees heretofore tried among us, except the holly, sufficiently exempt from fatal diseases, and easily procurable, to render them a safe reliance for hedging. And lastly, because the present law of descents—throughout the United States, which will never probably be changed for the English law of entails and primogeniture,—inevitably produces frequent subdivisions of landed estates, and consequent changes in their fences. Let us examine these objections seriative.

That live fences are more expensive than dead ones, seems to me manifest, for the following reasons: In preparing for your fence, you must dig a large ditch. If cedar be used, you must next collect the plants, according to Col. Taylor's plan, and cart them to the spot; but there are few portions of the United States wherein the cedar grows naturally, and to sprout berries I know to be a very uncertain process. After setting them in double rows, you must continue to cultivate them, once or twice a year, until they attain sufficient size and strength to protect the crops from what our Yankee friends call, "*breachy cattle*;" an adjective, by the way, which should be in all our dictionaries, as it forcibly expresses what no other single word in our language does. The period necessary for this purpose, I assert from my own experience, to be, on an average, ten or twelve years, where the hedge is of cedar; nay, still longer, unless there be a ditch and high bank to aid it. Manure too, must be several times applied; a protective dead fence must also be kept up, for several of the first years of its growth, to guard against the aforesaid "breachy" marauders; and at least one annual pruning must be given forever; unless indeed, the hedge be left to grow as nature prompts. In this case, if it divides two fields, it soon spreads, in such a manner, as to exclude from culture, at least one acre of the best land, in about every four hundred yards; whereas a fence of dead wood, or stone, or brick, excludes only the very narrow breadth on which it stands. Again, the hedge of cedar, even in its most perfect state, is, *of itself*, no protection against hogs that run at large, as they do in Virginia, and several other states, for the bottom limbs always die after a few years, leaving large open spaces. This is particularly the case with Col. Taylor's cedar-hedges, which I have seen three or four times a year, ever since they were planted; although at a little distance a careless spectator would not probably notice it. The ditch-bank on which the hedge stands, is generally so steep that hogs cannot climb it; or there are numerous places through which they could pass with perfect ease. This tendency to die in the lower limbs of the cedar, I have noticed in all the hedges of it that I have ever seen. But it is more observable in Col. Taylor's than elsewhere, owing, as I believe, to an error committed in the early management of it. I feel great reluctance to differ from such authority, and one too, who was a personal friend to whom I was strongly attached for many years before his death. But the error, if it be one, is important to all who may attempt to make cedar, or any other live hedges, of trees that grow with a single body, and I will therefore state it. Col. Taylor topped his cedars at the height of one foot, when they were only a year old, and trimmed the sides *perpendicularly*. The English authors on hedging, without an exception, as far as I recollect, and Mr. Kirk of Delaware, who probably has more experience on this subject than any other man in the United States, all recommend the topping to be postponed until it can be done about four feet from the ground; and the sides to be so trimmed, as always to keep the hedge wider at bottom than at top. The reasons assigned, (and they appear to me unanswerable,) are, that the longer the main stem can be suffered to grow, the sooner will each plant attain the requisite strength; and that to give the sides a conical shape is essential to their vitality, as each limb requires for this purpose its due proportion of light, air, and moisture, which it cannot receive if the sides of the hedge be perpendicular.

Now let us endeavor to show the comparative expense of fences made of dead wood, or stone. None of them have to pass through a long non-age, requiring a guardianship, for they are at maturity the moment they are put up. None of them require a preliminary ditch, although it may be advantageously used where materials are scarce or dear. None of them exclude from culture more than the very narrow breadth of land on which they stand; and they draw nothing from the adjacent soil to injure the crops, which may almost touch them while growing; nay, they actually benefit their growth, in some degree, by keeping the earth near them more moist than that which is more distant; and the rotting, (when made of wood,) is really a manure, however small it may be. None of them are *immoveable*, which live hedges *are*; but may be carried from place to place at no other expense than taking down and putting up. Again, the materials, in very extensive districts,—even of the old states, and nearly every where in the new ones,—cost nothing but the cutting, carting, and putting up; for they are often so much in the way of the proprietors, that they will actually give them to any one who will take them off. In all the Atlantic states, with the exception, perhaps, of the Carolinas, stone is a real nuisance over considerable portions of them, and must either be used in fencing or put up in large piles, to fit the land for profitable culture. But when once the stone fence is properly made, no farther labor on it will be necessary to the end of time. I have known, from my boyhood, one made of freestone, which is less durable than any other, used for fencing, and it has been standing more than fifty years, (how much longer I know not,) and not a minute's labor, I believe, has ever been bestowed on it, during the whole of that period. In regard to fences made of timber, I can also assert from my own long experience, that they will last, if made in the best manner, from six or seven to twenty years, without any other labor than that first bestowed on them. The time depends, of course, upon the kind of timber used in their construction. If the inclosure be all *above* ground, and such as we southerner's call a "*worm-fence*," which you and your northern readers may not possibly understand, unless I tell you that it more resembles what our mothers and grand mothers used to term "*herring-bone stitch*;" *such fence*, without violence from "breachy cattle," or "breachy" men, (which are far worse,) will certainly last from six to ten years, without the slightest repairs, unless a tornado or whirlwind has passed over it. To insure this however, it must be made of some one or more of the varieties of timber usually preferred, and cut at the best season. These, in Virginia, I believe, are ranked in the following order: yellow locust, red cedar, black walnut, chesnut, sassafras, black mulberry, white oak, heart pine, and red oak. I may mistake in regard to their relative durability, but not as to the time that a worm-fence made of any of them will last without repair, if undisturbed by accident, or design. If the inclosure be what is commonly called "post and rail," I again assert, from my own experience, that one made entirely of red cedar on my farm lasted eighteen years, without one moment's labor being bestowed upon it; and that many of the posts and rails are still sound, still in use, after standing thirty years, the fence having been taken down but once for repairs. The posts, when first put up, were rough, nothing more being done to them than to cut them of the proper length, and to bore them with a two inch auger, at proper intervals for the rails. To those also, which were made of the bodies of small cedar, of various sizes, nothing more was done than to trim off the limbs, to cut them of the proper length, and to make round tenons at each end, that they might fit the holes in the posts. A small portion of the rails of the largest size were split into two pieces. Yellow locust posts, I know, will last longer, in general, than cedar; and I have been assured, from good authority, that catalpa is as durable as locust. Here then we have three varieties of timber, two of which are common in many parts of our country, and the third might soon be made so,—of great durability, when sunk in the earth, even without charring; while we have several others that will last for many years, if charred before inhumation; and still more, which remain sound for ten, fifteen or twenty years, when used above ground. We may assert it then, as an incontrovertible fact, that fences of dead wood, if made of the most durable kinds of timber, common in the United States, and carefully put up, will last, on an average, from six or seven, to ten and twenty years, *without expense;* whereas *some* annual expense *must* be incured to keep up a live fence as long as it lives. Let those whom it concerns compare the cost of each, for one generation or more, and determine accordingly.

I had almost forgotten to mention stump-fences among those which are preferable, in certain situations, to live hedges. The invention of that excellent implement, the *stump-extractor*, must soon render these formidable inclosures common in every part of our country, where much land has been recently divested of its timber, and of this we have some millions of acres. Your farming gentry who go more for the new-fangled,—although already hackneyed,—term, "*picturesque*," than for the *profitable*, will utterly eschew them, as too revolting both to sight and taste; but brother Jonathan, whose preference of the *useful* to the *showy*, where they cannot be united, I most cordially approve, will cling to the stump-fences as long as there are materials to make them, and will leave the live hedges for pets to their dandy brethren; for (with regret be it spoken,) we have dandies in farming as in every other walk of life. Not that I wish, by any means, to rank all hedge-makers among our brother dandies, for I am sure that many of them are actuated by the true spirit which should actuate all the genuine friends of husbandry; but if any should appear among us, as sometimes happens, who are not governed by this spirit, but proceed as mere fancy prompts them, no "esprit du corps," I think, should prevent us from attempting to guard novices against their influence.

My next objection to live fences is, the number of fatal diseases to which *all* plants or trees, heretofore tried among us for the purpose of making them, are liable, except the holly. This tree is sui-generis, in regard to its exemption from disease, and its throwing out limbs, even touching the ground, which live and flourish quite as well as all above them. Another peculiarity is, that the browsing of cattle and sheep on the extremities of the limbs, improves it in such a manner, that it soon becomes quite as dense and close, as the best trimmed garden lot. Our worn-out old fields, in the tide water portion of Virginia, left uninclosed and abandoned to nature's restorative influence, exhibit thousands of proofs of this fact, for the holly abounds in such grounds; and many of our poor cattle and sheep, left also in a great measure to the same all-bounteous nurse, have been instinctively led to the holly as a pretty good anti-starvation article. Of these we have also the pine and the cedar to aid the holly, or heaven only knows how large numbers of our stock would keep life and body together during a considerable portion of the year. The objections to the holly are,—the extreme difficulty of making its berries vegetate, and its uncommonly slow growth; for many of our brethren seem to hold with the Irishman, who swore that, "*as posterity had never done any thing for him, he would never do any thing for posterity*."

Although fences of this excellent hedge-plant are represented as common, both in England and Scotland, by all their agricultural books, I have never known nor heard of but one attempt to make a holly-hedge in our country. This was in my own county. It was nearly a mile in length. Great care was bestowed upon it, at first, by the projector; but his Virginia-patience failed long before the hedge could have reached maturity. Utter neglect was the natural consequence, and his successor, (not his heir,) wantonly cut it down. A few obstinate stumps, however, still testify to the vitality of the holly, which nothing but fire or extirpation can kill, and to the reckless attempts of man to destroy or reject it, notwithstanding its admirable capacity to prove the best friend of all hedge-fanciers.*

The other plants or trees that I have known to be used for hedges, are the English hawthorn, two varieties of the American thorn, the Pyracantha or evergreen thorn, and the honey locust. Two experiments only, with the latter, have come to my knowledge. The first was made by myself. I planted the seed, after soaking them in hot water until they swelled considerably, in which state they, as well as the seed of the yellow locust, and several other similar seed which I have soaked in the same way, will come up as readily and certainly as peas or beans. The plants, however, after growing two or three years, and being cultivated during the time, began to die in spots; while those which survived, threw out so few side-limbs, and manifested such a tendency to grow erect, that I extirpated them. The other experiment was mentioned to me, many years ago, by Mr. Rufus King, our former minister in England, who told me that it failed with him. He made the same objection as I have done to this tree. Of thorn hedges I have seen several in Maryland and Delaware, and a few in my own state. All of those in the first mentioned states had gaps in them, where the bushes had died, apparently from some disease or other. They were chiefly of the maple leaved thorn, as well as I recollect. The most considerable trial that I have ever known, in Virginia, was commenced, many years ago, under the directions of an English farmer, near Fredericksburg, on the main stage road, and with at least two varieties of thorn, the English hawthorn being one of them. This hedge did not succeed; but at the death of the first projector, the farm became the property of the present proprietor, who made an effort to revive and extend it, at least a mile in length, chiefly, I believe, with the maple leaf thorn. From having passed it several times a year ever since, I can testify that no man could well have taken more pains to insure success, yet nearly all the thorns are now dead, and the remainder fast declining. This trial having been made within two or three miles of the head of tide water, I think it fair to infer, that none of the thorns could be relied upon for hedges, in any of the tide water portion of Virginia. Farther south, I presume, they could still less be depended on. Of the pyracantha, I have seen but one small hedge. That was in Maryland, but although beautiful to the eye, it was evidently no protection against mischievous stock, nor did it appear capable of being made so. Our red cedar is liable to two incurable diseases, one of which seems on the increase, and is constantly killing thousands of the trees, as they grow naturally in our woods. It is a worm in the roots, that accomplishes its work of death, before the limbs and leaves give any warning of it. The other cause of their destruction is also a worm or insect, which attacks the trees above ground, and soon colonizes them with innumerable cocoons, which are attached to their tenderest branches, and soon kill them.

---

* For the information of those who plant hollies to ornament pleasure grounds, I will here state, that we have several varieties in Virginia, producing, in great profusion, berries of various shades of scarlet, from the brightest and richest, to that of a paler hue. We have two other kinds, whose berries are of a pale orange color, the one being somewhat deeper than the other. These however, I believe to be scarce, as I have never found them, except on my own farm, and one other. The holly with variegated leaves is not a native.

The Osage Orange, of which we have lately seen some very favorable accounts, has not yet, I believe, been tried in the Altantic states; and the non-descript, or evergreen Carolina rose, I know, from personal observation, will not flourish in the latitude of Virginia. There is one remaining objection which is common to all the plants and trees I have enumerated:—that is, the comparatively small portion of our country in which they grow naturally. None can be found but in particular regions, and these are of no great extent, compared with the whole territory of the United States.

My last objection to live fences, as a general system of inclosure, is altogether insuperable, unless, indeed, the old laws of entail and primogeniture were re-established. The existing law of descents, in all the states, I believe, without exception, compel a division of property, in every case of intestacy; and so much is the practice favored by public sentiment, that even where a will is made, the testator himself, in ninety-nine cases, probably, out of a hundred, directs a division. If the property be land, and it be cut up into several parts, this necessarily produces almost an entire change in the inclosures. Some must be pulled down and others put up where none stood before; and should they happen to be live hedges, to *remove*, is to *kill;* whereas either rail or stone fences may be changed, without any other expense than transporting and re-erecting them.

Upon the whole, then, I conclude that live fences, in our country, are no where preferable to those made of rails, or post and rails, unless where timber is very scarce and dear, or near large towns, where inclosures of dead wood are liable to be burned. Even there, I deem it demonstrable, that stone walls would be far cheaper, if the materials could be procured near at hand; and if not, that walls of brick would be vastly preferable, especially if made according to the cheap plan recommended in the third volume of the American Farmer, page 262, by Mr. William Noland, the present superintendent of the public buildings in Washington.* This article is so worthy of public attention, that I would have copied the whole, in this letter, if I had not feared that my communication was already too long. I must take the liberty, however, strongly to recommend it for republication in the Cultivator.

I remain, dear sir, your ob't ser't,
JAMES M. GARNETT.

REMARKS.

We either did not sufficiently explain our object in the publications which we have made upon live fences, or have not been understood by our highly respectable correspondent. We did not intend to recommend the culture of live fences, as a *substitute* for stone walls in stony districts, nor for post and rail, or post and board fences, where these materials abound, nor even for substantial white pine stump fences—for like our correspondent, we think these are to be preferred where the materials are abundant or cheap. But there are large districts of our country, particularly in the west, where there are neither stones nor pine-stumps, and where fencing timber is already scarce, and likely to be more so, from which we have received frequent inquiries in this matter: And although we are disposed to pay the highest deference to the opinions of Mr. Garnett, he will pardon us for persisting in the hope, that we have plants, indigenous to our country, which will make good hedges, and that it will be found practicable and economical, in the long run, to cultivate live fences in the districts to which we have alluded. We adduce our own as a case in point. Common stone costs us two dollars a load. Wooden materials for fence are almost as expensive, and their duration, except the posts are cedar, which cost nearly fifty cents each, does not exceed ten or twelve years. These circumstances induced us to attempt to raise hedges; and to try the English and native thorns, and also the honey locust. Although we cannot confidently assert that we *have been* successful, we can say that we believe we *shall be* successful with both the native thorn and the honey locust. As yet we have experienced no injury from disease or insect, though the ground mice have done us some damage, in our hedge as well as in our fruit and other trees. The comparative expense of dead and live fences never engaged our attention, though we recollected that Caleb Kirk had endeavored to show, and to our mind had done it satisfactorily, that the latter were to be preferred on the score of economy. There are besides considerations in favor of live fences, which apply with some force in the prairie-west, and in the north, which do not apply in Virginia: they are wanted as *shelter*, to protect the crops from the severity of the winter blast.

With this explanation of our motives, we have no reason to regret that we have been misapprehended by our very able correspondent; because it has been the means of procuring us a valuable essay on the subject, which we feel assured will be read with interest and profit by our patrons, whose interest it is our duty to serve.—*Cond. Cult.*

Farm Machinery—Peat Earth.

Wheat-Sheaf Farm, Staten Island,
December 18, 1837.

J. Buel, Esq.—Dear Sir,—I received your esteemed letter of the 20th ult. requesting a communication from me as to my mode of improving and fertilizing my farm, and a *description and drawing of my machinery.* In withholding the latter, *for the present*, I am actuated by an apprehension, that in so far as experience may hereafter suggest *changes*, I may regret having given publicity to it, while yet imperfect. It has much of novelty, and observation upon its practical movements yet continues to suggest guards and alterations, more or less essential to its operations in the most perfect state in which I may be able eventually to put it. Since I had the pleasure of shewing it to you, I have concluded, (as I believe I then suggested I might,) to adapt it to *public*, as well as my private, uses, by adding an eighteen horse *wind* power, with four run of stones, to be applied, at pleasure, independent of, or in connection with, the four horse farming and foddering power I then exhibited to you, and to make it what I call a *Foddering and Grist Mill*, for myself and the vicinity. I become daily more and more convinced it may be made both useful and economical. If it does not prove so in the sequel, I should myself call the further pursuit of it little better than folly. I never yet was disposed to "*flash a shew*," lately so prevalent, and trust not to have begun with this. Of one thing I am sure, that farmers reflecting on it in the quietude of their habits and occupations, would never feel disposed to approve it, if it could not be made both useful and economical, as well as profitable to them to do so.

In Europe, a labor-saving machine, if not a curse, at least is calculated to draw down the imprecations of the suffering poor upon the head of its inventor—while here, where we have more of labor than laborers in the vineyard, such an implement is hailed as a blessing. It, as it were, adds to the laboring *population* of a country yet growing towards its maturity, and the incentive which, as a substitute for labor at a high price, it gives, makes us what, from *local circumstances and exigencies*, we are, the most inventive people on earth.

On referring to Loudon's Agriculture, (in the Supplement, page 1277,) you will find a notice of a threshing machine, said to be one of "the most complete agricultural implements in England," bearing some resemblance in its objects to *a part* of mine, but effected through a medium infinitely more expensive and complicated, and of which I had no knowledge till after mine was constructed. Erected, as that was, specially for and under the patronage and high protection of the Duke of Gloucester, Loudon mentions it "as a singular and melancholy sign of the times, that the parties who had the chief merits of the invention, were *afraid of giving their names to the public*. The agriculturists (says he) of a future, and we trust no distant day, will hardly believe it possible that the destruction of threshing machines should have been *popular* in England in 1830."

I thank heaven my lot was cast where, if I realize my views in this, there will be none to censure them; and where, above all other places, he emphatically does the human family the best service, who makes two blades of grass flourish where but one had previously languished. "If (as you say) there is a pure pleasure to be derived from human actions, it *must* be found in a disinterested endeavor to benefit our generation and our country." If it shall be my lot, in the *busied retirement* to which I have *fled*, to effect such an object, I shall, indeed, not have lived without an end, and will die comfortably.

But in reply to your letter. I can only for the present, on the subject of my machinery, say with you, that "*barring accidents*" and "*in good time*," I shall not fail to comply with your wishes. Its scope and objects, in part at least, are generally explained, if your notice of it in your August number (page 100) is referred to, and taken in connection with this letter.

As to the other part of your request, "my mode of improving and fertilizing my farm," I find *that* too general for *one* communication. I shall, "since you will have it so," on a future occasion, comply cheerfully and more at large; for the present, however, there is one you have adverted to in your last number, (page 157,) which has much interested me, under a perfect conviction I always entertained, that swamp earth might be used with more advantage than usual with us. With "Peat Earth and Peat Ashes" I was wholly unacquainted when I came to my farm; but in the process of clearing and bringing under cultivation its "worse than useless" parts, I sought information through channels similar to those to which your article refers. I have reason to thank you for the account it gives of the Dutch and Flemish practice. Their books I had sought in vain in New-York, but I am pleased to find them consistent with such as I have had access to. Permit me, in return for the advantage I have in this derived from your columns, to refer you and your readers to what I have met with on the same subject. The swamps which furnish peat earth or turf, nine-tenths of the laboring Irish emigrants are familiar with under the local appellation of a "*peat moss*." They generally seem to be so with the burning of it, and practically with the different modes of disengaging from it the acids which check its putrefaction, and consequent adaptation to vegetable nutriment. They have served their apprenticeship to it as agricultural laborers in the noted bogs of Ireland.

The use of peat earth led to much disappointment in Great Britain, until Lord Meadowbank scientifically explained its properties, uses and modes of application, and I believe him to have been the author of the present practice both there and elsewhere in relation to it.

Loudon says, (pages 745 to 747,) "mossy and boggy surfaces occupy a very considerable portion of the British Isles. In Ireland alone there are of flat red bog, capable of being converted to the general purposes of agriculture, 1,576,000 acres, and of peat soil covering mountains, capable of being improved for pasture, or beneficially applied to the purposes of plantations, 1,255,000, making together nearly 3,000,000 of acres. Black mosses, though formerly considered irreclaimable, are now found capable of great amelioration. By cultivation they may be completely changed in their quality and appearance, and from a peaty, become a soft vegetable earth, of great fertility."

I leave you to insert as much further of this reference as you may deem best for the guidance of your readers. It will however serve to shew, in a *great many* districts of both England, Ireland and Scotland, a general practice similar to that you have yourself quoted as to Holland and Belgium, and which I have no doubt prevails in the north of Europe. I had myself seen none but the *Chat* moss, over which the Liverpool and Manchester rail-road lies; but then the idea occurred to me, that it might, by drainage, be similarly applied, and as I find, by the last edition of Loudon, it now is. On draining my swamps, I discovered in the ditch, about three feet below the surface, a compact stratum, say twelve inches thick, exclusively of *leaves* and of minute vegetable fibre, so small as to decay under an *ordinary* exposure to the atmosphere, in a few days or weeks, and which, in this swamp, (as I infer from the superincumbent creation,) must have resisted decay 1,000 years or more. The mossy soil above consists entirely of the imperfect decay of subsequent vegetable growth, and which has probably not so effectually resisted decay, on account of its occasional exposure, superficially, to the influence of the sun and air during the drier seasons of occasional years of great drought.

---

* This article shall be copied into the Cultivator as soon as our limits will permit.

Loudon says, (page 345, No. 2238,) "Marl and even shell sand have been known to act chemically on peat bogs, and to produce astonishing benefits. True and genuine peat bogs contain a considerable quantity of an *acid*, which has some affinity to *gallic* acid, and often yields phosphoric acid to analysis. It appears to be these acids which confer on peat its highly antiseptic qualities, and prevent the complete decay of woody fibre in such situations. When either true marl or shell sand is laid as a manure in such soils, a rapid decomposition of the vegetable matter takes place, owing to the calcareous matter uniting with the acid, which before impregnated the woody fibre, and such land soon becomes very productive, probably also because the carbonic acid of the marl and shell sand is applied to the growth of living vegetables, as it is gradually disengaged by the union of these acids with the lime."

Deane's New-England Farmer, under the head of peat, page 323, refers similarly to it, and the mode of using it.

The Complete Practical Farmer, an American book, very generally possessed, page 30, under the head of peaty substances, also describes the process.

Sir Humphrey Davy says: "Inert peaty matter requires fermentation to render it nutritive to plants. It remains for years exposed to water and air, without undergoing change, and, in this state, yields little or no nutriment to plants. Woody fibre will not ferment unless some substances are mixed with it, which act as the mucillage sugar and extractive or albuminous matters with which it is usually associated in herbs and succulent vegetables. Lord Meadowbank (he says) has judiciously recommended a mixture of common farm yard dung for the purpose of bringing peats into fermentation. Any putrescible or fermentative substance will answer the end, and the more a substance heats, and the more readily it ferments, the better it will be fitted for the purpose. And he states that one part of dung is sufficient to bring three or four parts of peat into a state, in which it is fitted to be applied to land; but of course the quantity must vary according to the nature of the dung and of the peat. In cases in which some living vegetables are mixed with the peat, the fermentation will be more readily effected."

I have occasionally, in the absence of guides, tried these substances and failed, and in some instances have succeeded. Two or three experiments of my own are now in progress, which are, as I apprehend, checked more or less by the counteracting tendency and operation of frost. I shall, for the present, suspend a communication already longer than I intended to have made it, again to resume it, if you wish, when I shall have better tested them. But in so far as your last number has described these substances, they are consistent with my observations, and I think undoubtedly applicable. This, however, should probably be borne in mind: I use *more* of the ashes to the acre, because my swamps contain little or no calcareous marl beneath them, and an analysis I apprehend would therefore not find so much of the sulphate and carbonate of lime as that which professor Brande analyzed. The two which you saw are incumbent on a *clay* marl, little if any embued with calcareous matter, or other than of vegetable impregnation, valuable to ameliorate the texture of a soil too prevalent of sand, or to improve the capacity of upland for holding manure in solution from which alluvial influences have taken an undue proportion of clay. The marl is followed under it, in a distinct stratum, by a stiff pipe or porcelain clay, which, with the marl, made it heretofore so perfectly impervious to water, that although no other than alluvial supplies immersed it, it seldom, if ever, was known, before it was drained, to be dry. The level of the present drain is about nine feet below the former fullest water surface.

Believe me, with great respect and esteem to be, very truly yours, W. A. SEELY.

Entomology, &c.

Bath, *Feb.* 3, 1838.

Judge Buel,—Sir,—I have read your valuable paper with much pleasure for two years, and now send you the subscription price for another year. You have mentioned the Humic Acid in several of your papers as being a substance lately investigated by some of the German chemists. I would inquire if you have seen any chemical analysis of the Humic Acid, either in any work on chemistry, or in any of the journals, foreign or domestic, and if so, if you will publish the analysis, with the physical and chemical properties of the said acid, in the Cultivator.* I made the request, last winter, to have some additional information in regard to the entomology of our country, communicated from some of your many correspondents. A class of animals that exercise so important an influence over the labors of the farmer ought to be better known. The first object ought to be perhaps to distinguish in the innumerable insect tribes between our friends and enemies. It is a well known fact to readers of natural history, that a vast and interminable war of destruction is carried on between the different insect tribes, and therefore it may be for the interest of man to encourage the conqueror in their exterminating conflicts, is an object of much solicitude and of high interest. As an instance, a few years since a remarkable insect, somewhat resembling the black wasp, but longer shaped, somewhat more like the hornet, but of a shining black, and very active, was pointed out to me as the natural enemy of the grub worm. Its evolutions when on the ground were similar to that of the hound upon the track of the hare. Its head was down, as if in the act of smelling, and every few minutes it would dig with its fore feet in the manner of the dog. At length it dug up a worm, stung it to death, and left it. On a succeeding day I saw the same insect engaged in burying the victims of its warfare. A hole was excavated in the soil sufficient to deposite the worm by the use of its fore feet. The dead worm was then seized by the forcep jaws of the insect, who drew it backwards into the hole into which it entered in rear of the worm, and from which it immediately emerged, and scraping the earth together raised a tumulus over the grave. These facts may be familiar to the professed entomologist, together with the name and the habits of the insect, although they were new to me. Another circumstance in natural history I will mention, as I have not seen it noticed by any writer.—Passing a ploughed field, in a meadow free from stumps and stones, one day in the summer of 1819, I was surprised at the notes of what I considered a fine singing bird, which I called into repetition some few times, until I discovered the melodist, which, to my astonishment, was no other than the little brown snake with a yellow ring around its neck. Had it been a bird, I should certainly have complimented it as a very agreeable songster. I have mentioned the remarks on the aforesaid insect, to illustrate the kind of information we want in regard to the insect tribes.

Wishing you every success in your laudable endeavors to enlighten the farmers of our beloved country, I am, sir, sincerely your friend,

MOSES F. MORRISON.

Farming—New Kinds of Wheat.

Galena, Ills. 22d January, 1838.

Jesse Buel,—Dear Sir,—From my youth I have been fond of agriculture. This fact, and a desire to obtain information, are my only excuses for now troubling you; I then thought I would be a farmer, but circumstances led me to other pursuits. I wished to make a fortune before I would turn my mind to agriculture. Why was I not wise enough to say at once, I will become independent by frugality, industry, and farming? It appeared to me to be too slow a way to wealth, although I was aware of the advantages of a farmer's life, viewed physically and morally. Well, sir, after years of trouble in business, my attention was, thank God, again directed to farming, and since three years, my time has been mostly taken to that business on my farm, situate three miles from Galena. Of course, I could not be long a farmer without taking your Cultivator. I have been more than ten, yes, than an hundred times repaid, by the useful information I have received, for the small pittance I have given in return, of 50 cents per year. I see with much pleasure that you intend to increase the size and matter of your useful paper. I shall continue to be a subscriber; I will also subscribe for my brother at the office of the Galena Advertiser. When any of my neighbors call on me for information about farming, I say, do you take the Cultivator? If they answer no, I tell them, go and subscribe for it, and you will hardly need lose time to question your brother farmers about the management of your farms.

My friend, Mr. A. E. Hough, of Gibralter, Wisconsin, gave me a few grains of your Buel corn. I will take great care of it; the pains you took to send those seeds so far, induce me to send you here inclosed a few grains of bald spring wheat, brought, at first from Lord Selkirk's settlements, on North Red River. I sowed the wheat, from which this seed was gathered, on the 15th of May last; you can judge of the quality by the specimen sent; it came to maturity perfectly, without smut or rust, producing at the rate of 30 bushels to the acre. I have, also, a many headed wheat, brought from Santa Fee, in New Mexico. It bears from 9 to 15 heads per straw, counting the centre and side heads. I think it differs much from the Egyptian wheat, the berries are very large, white, and plump; it is said to be a spring wheat. I sowed in a drill, (about half a gill of it) last spring, on the tenth of May. It grew luxuriantly, producing heads of such large size, as I never saw before, but at the approach of its maturity it shrivelled up, the berries being very deficient. I will plant it again, at various periods, so as to ascertain, if I can, the best moment. In the Santa Fee country it produces at the rate of 60 bushels per acre. Can you give me any information about the culture of this wheat?

I am, very respectfully, yours, &c.

JAMES G. SOULARD.

Transplanting—Potatoes—Italian Wheat—Ploughing old Meadows.

Clinton, *Oneida co. Jan. 5th*, 1838.

Mr. Buel,—Sir,—As the earth is composed of atoms, and the ocean of drops, so the columns of the Cultivator may, perhaps, receive an accession of interest from sources comparatively small. A few brief remarks are all I propose to offer.

1st. With respect to transplanting. In the early part of December, 1836, I procured a lot of apple trees, and set them the next day, (roots partially froze during the night;) the ground being naked and clear of frost. The next season witnessed a fine growth in every instance; numbers of them blossomed, and one bore about a dozen apples to maturity. The suggestion I would make is, that late fall, or winter setting when practicable, is preferable to performing that operation in the spring, as the earth becomes adjusted to the roots by the long action of winter, being thereby less exposed to perish by drought or other causes.

2d. As much difference of opinion exists, whether large, small or medium size potatoes are best for seed, I made a trial of the two extremes in the following manner, viz. by planting two rows with one potato of the largest size in each hill; then two with three of the smallest in each hill, placed in a triangular form, four inches apart, soil similar and very rich. Result—the potatoes from the first two rows were generally larger than those from the other two, (though all were large, and the yield about one-sixth greater.) As truth is said to lie between extremes, as a general rule, perhaps this case is not an exception.

3d. Italian wheat. My experience here is limited, having raised but a single patch of forty-eight rods, from which I obtained eight and three-fourths bushels, being at the rate of twenty-nine bushels per acre. The crop was diminished by smut, the straw bright and grain heavy, weighing more than sixty-one pounds to the bushel. I beg leave here to suggest the importance of making all statements of crops for publication, from *actual measurement*, both of land and product. The superiority of this variety of spring wheat is thought by many to consist chiefly in its adaptation to worn out or light soils. My field had been in tillage forty years, with, perhaps, one exception. As far as my observation extended the past season, the growth was abundant, very little injured by rust, and I am not at present willing to abandon its culture. If on further trial some other species shall be found preferable, of course they will supersede it, as improvement is or ought to be the object of every farmer.

4th. In conclusion, I would reiterate your oft-repeated recommendation, to plough up old worn-out meadows, and keep them in tillage two or three seasons. My own experience, though not great, enables me to say that on a piece of meadow thus renovated, I have for several years cut triple the amount of its former product.

I am, sir, with respect, yours, &c,

G. BUTLER.

Relative Value of Ruta Baga for Fattening Oxen.

Scaghticoke, *Feb.* 3, 1838.

Sir,—Believing the turnip culture to be of almost inestimable value to the farmers of this country, and knowing the strong prejudices entertained by the most of them, against any thing like innovations, or deviations, from the good old ways of their fathers, as they term them, I deem it the duty of the few, who have been credulous enough to cultivate a few acres, to say, what they can, from experience, to induce others to give them a fair trial, and a chance to grow upon a few acres of their poor sandy soil, that will hardly grow any thing else, and they will find, when the *summer* is *passed*, and the *harvest ended*, that they have not been imposed upon, except by the large quantity of roots. And, it was my object in commencing this article, to show what I believe to be their value, for feeding, in comparison with other grains and roots, generally used. I will first state that my crop was about 950 bushels per acre, on a light, sandy soil, without manure, ploughed but once, and hoed twice, the whole expense, including interest of land, was less than 3 cts. per bushel, a price which I have frequently paid for digging potatoes, and the same land would not have produced 200 bushels. I fed 2 yoke of cattle on them for 2 months, viz: November and December, feed 5 bushel per day, a yoke. Average gain 115 lbs. a yoke per month. The same cattle were fed through the month of January, on potatoes and meal, corn and oats, ground together in equal quantities, feed 2 bush. potatoes, 1 bush. meal. Gain 60 lbs. Estimate the value of the ruta baga, by the present price of corn, oats and potatoes, and the respective gains, and it makes the ruta baga worth but a fraction less than 48 cts. per bushel; that is, if corn is worth 8*s*., oats 4*s*., potatoes 2*s*., for making beef, we must put the ruta baga at 48 cts. I will only add that the experiment was fairly tried, the cattle were weighed correctly, and eat their allowance every day.

---

* *Humin, humis, humic acid.*—These seem to be but different names for the same substance, and but *new* names for the black carbonaceous matter of dunghills—the fertilizing material of soils. The principal elements are carbon and hydrogen, with more or less of other matters, as oxygen, nitrogen, oxides, and earths. We will speak more at large upon this subject in our next.

Yours, respectfully,
JOHN C. MATHER.

Cure for the Scours in Calves, &c.

Scantick, E. Windsor, Ct. Jan. 17, 1838.

Judge Buel,—Dear Sir,—About ten years ago I happened to observe a young man busy about a sick calf, endeavoring to force it to taken some medicine, and on inquiry I found the disease to be what the farmers here call the white scour, or a drain horn of a light ash color. He was a large well formed bull calf, of the Durham breed, but was apparently near death, being excessively weak, having refused all food for several days. Believing the disease to be caused by acidity, and to depend upon a suppression of the secretions from the liver, I directed five grains of calomel to be given once in four hours, until the evacuations assumed a darker color. This was done. The white purging was checked by the first dose, and in some twelve or fifteen hours after was followed by evacuations much resembling tar in consistence and color. This change was followed by complete relief; the appetite and strength returned, and the calf proved to be a very valuable animal.

Since that time I have almost every year given calomel in this way to calves thus affected by the white scour. I have not known a single instance in which it has failed of effecting a speedy and complete cure. I have commonly advised scalded milk to be given, to prevent a relapse.

Some time last May, being at the residence of my father-in-law, I noticed one of his swine, a fine huge barrow, apparently very much exhausted, and was told that it had had the lockjaw for nearly a week previous, and that during that time, it had not swallowed a particle of food, or a drop of liquid, and that it was impossible by any means to force his jaws open, even in the slightest degree. Suspecting another disease, I directed an examination of the glands back of the angle of the jaw; these proved to be excessively swollen and very hard on each side. A deep incision was immediately made with a sharp knife into the substance of each gland, through a wound in the skin, about three inches long. Half a tea-spoonful of a mixture of calomel and lard was crammed to the bottom of the wound, and the skin being closed by a single stitch, the operation was completed. In less then two hours the hog ate freely, and in a fortnight was apparently perfectly well.

If these facts can be made useful to you in any way, you are at liberty to make what disposition you please of them.

I am, sir, very respectfully, yours, &c.
H. WATSON.

Mode of Planting Cedar Hedges.

Judge Buel,—In looking over number 11 of the present volume of the Cultivator, I notice the method of planting a cedar hedge, as recommended by John Taylor, of Caroline county, Va. and as I should infer, also advised by the Cultivator.

I have at least as handsome a cedar hedge as I have ever seen, and raised with, perhaps, one-twentieth part of the trouble that is required to dig up and tansport each plant, with some fifteen or twenty pounds of earth attached to the roots, as recommended by him.

My plan was this: on the last of the third month, (March,) 1823, a trench was first partially opened to the width of a spade; the remaining earth to the depth of nine inches, was worked to a fine mellow state, and not removed. With the aid of a small boy, in about one day, I obtained the plants from the fields, and nearly finished the planting; a single stroke with a grubbing hoe, near the plant, would loosen the soil, and then removed carefully, *but without any earth attached to the roots.* The plants were from six to eighteen inches high, and the roots of each dipped in water, as planted. They were placed in a single row, from four to six inches apart, requiring from 300 to 350 plants; and out of this number not one dozen failed to grow. The hedge is about forty yards in length, (separating my yard and vineyard,) and so close as entirely to obstruct the view from the opposite side; is about eight feet high, and from four to five feet through at bottom; the average size for eight or nine years past. The annual pruning will soon reduce it to six feet high, and about two and a half feet thick.

A common farm hand will prune it in a few hours, and it then presents a beautiful appearance; the top is clipt with pruning shears, and the sides with a common mowing scythe, very evenly and expeditiously, mowing *perpendicularly.*

No hedge that I have met with, is more ornamental; and few are made with less labor; if care is taken to keep them well pruned, there is no danger of their not being thick enough at bottom.

If the above hasty remarks are considered worth a place in the Cultivator, please make use of them.

I am respect'y, E. S.
Harewood Montg'y co. Md. 1*st mo.* 8*th*, 1838.

Remark.—We thank our anonymous correspondent for the above valuable communication. The red cedar grows upon most of the Atlantic border, and we are *now* satisfied, that with moderate care, red cedar hedges may be made to grow and do well. We did not intend to *recommend* Mr. Taylor's mode of planting; in fact we did not give the matter a thought—considering Mr. Taylor's authority as sufficient. But we *do* recommend the above mode with two slight variations; first, that the roots of the plants be dipped in a thin grout, that is loam and water made of the consistence of porridge, and that the transplanting be delayed *till the spring growth has commenced*—it satisfactorily appearing, from experience as well as philosophy, *that all evergreens are most successfully transplanted while in the progress of growth.* It may be well, after the planting is done, to cover the ground about the roots with straw or litter, to prevent evaporation.—*Cond. Cult.*

Book Farming Considered.

Whalen's Store, 20*th Jan.* 1838.

Dear Sir,—I have been a constant and much gratified reader of the Cultivator, since its first commencement, and have taken much pleasure in introducing it to the notice of my neighbor farmers. In a few cases I have been successful, would that I could say so in all. I consider the money paid for it an investment that will be repaid to the intelligent farmer, with tenfold interest, and that too in most cases before the subscription year expires. The common objection I find, is its being "Book Farming;" to do away this absurd notion, I conceive to be of great importance; remove this film from the eyes of the agricultural community, and you have at once a large and rapidly increasing circulation. The lawyer, physician, divine, and mechanic read; and for what? to get the opinions and experience of those that have travelled the road before them; to get arguments and ideas that a life time of experience might not give. True, practical knowledge is good in all cases, as far as it goes; but how many rocks and quicksands in our journey through life should we not shun, did we but take warning from the many monitors continually issuing from the press, guiding us like beacons of light to the lone mariner in the way to the wished for haven. Agricultural periodicals bring us into an acquaintance with those far distant from us, and of whom we could know nothing, except from their communications. One sits down and gives a long list of failures before a profitable result has been attained; now in half an hour's reading we gain, perhaps, what our informant has spent years of toil and anxiety to obtain. Another gives a description of a building, farm implement, plan of draining, or making, perhaps, a fence or gate, bringing the subject to our mind's eye, in so plain a manner, that we may be said almost to have ocular demonstration of the same. Now, instead of travelling for this information, it is brought to our fire-side, where, during the long winter evenings, we can con it over at our leisure, and judge of the propriety of adopting or rejecting it. I am far from recommending the adoption of every new theory in agriculture; but when a long series of experiments have terminated in continued favorable results, then why not adopt them, particularly if reason and judgment speak to us in their favor. Let us then away with the ill-founded prejudice against "book farming," and let each farmer take an agricultural paper for one year, and my word for it, that ninety-nine in a hundred express themselves more than amply remunerated for the expense. A thought struck me, that the circulation of the Cultivator might, in many cases, be extended by an offer to refund the subscription at the year's end, should the paper fail of giving entire satisfaction; the subscriber returning the papers in order to the office, or its agents; believe me, the drawback would be small. Again, let each subscriber introduce the Cultivator to his neighbor that is without it, and see if he cannot add at least one to the subscription list; would they do so, its circulation could easily be doubled.

I can lay no great claim to either book or practical farming; but were I to be deprived entirely of reading on the subject, I should consider my progress much retarded, and the prospect in the future a cheerless one in the extreme.

With unfeigned wishes for the success of the Cultivator, and all its kindred prints, permit me to subscribe, your ob't serv't.

J. Buel, Esq. SETH WHALEN.

Siberian Wheat.

Stamford, Del. co. Jan'y 19*th*, 1838.

Mr. Buel,—Dear Sir,—I have read with pleasure and profit, the various communications in the Cultivator on the subject of improvements in agriculture, and amongst these, my mind has been led to the introduction and selection of the best kinds of seed, as one which ranks high in value to the farmer.

My object in this communication, is to give to the public, through the medium of your very valuable paper, my experience in the growth of the Siberian spring wheat. About the 6th or 7th of May, I sowed three bushels and four quarts of Siberian seed on three and a half acres of ground, planted the previous season with corn; the soil middling for the ridge land in this county, though never manured. The tillage, owing to unavoidable circumstances, poor, it being ploughed but once, and that poorly and lightly; harrowed one way. About one and one-fourth acres of this was thickly infested with brier roots, which sprouted and grew so luxuriantly as to destroy at least one-fourth of the crop on that part of the field I harvested 1,485 sheaves; have threshed 638, which produce 43½ bushels of first rate wheat. The sheaves threshed being an average of the whole crop, I have no doubt but I shall have 100 bushels.

The above is the result of my first crop under very disadvantageous circumstances. Were I to venture an opinion of a future crop with good tillage and favorable season, it would be much larger; but I find "guess work" meets with a rebuke.

I will, however, venture one comparison, since I have reduced it to matter of fact. In the same field with the Siberian I sowed my common spring wheat, on land equally as good and tillage the same, with the advantage in favor of the common, that it was sowed at the rate of one and one-fourth bushels of seed to the acre, and in consequence of the grain being smaller, I judged that there was twice as many plants on a given quantity of ground of the common, as there was of the Siberian. Both sowed the same time. The common came in about one week before the Siberian. Both kinds full and plump kernel. The straw of the common somewhat rusty, and some smut; the other straw bright and lustrous, and no smut. The common produces eighteen bushels per acre; the Siberian, as you will see, making a fair allowance for damage done by briers, about thirty-three. I saw also, on examination, considerable of the works of the Hessian fly in the common; only two plants in the other.

Thus I have endeavored to give the public a fair and candid statement of my experience in growing the Siberian spring wheat. Whether it will be considered very like a "bed-bug," or another "harbinger of summer," I cannot tell.

Yours respectfully, GEO. STURGESS.

Ruta Baga—Italian Wheat—Crops generally.

Oxford, Jan'y 14*th*, 1838.

Dear Sir,—I made a good crop of ruta baga last year. Not as large crop as others have mentioned, but it was a fair crop, 360 bushels from half an acre, from seed I bought of you, and they were good. I find them excellent food for all kinds of stock. Fat cattle, cows, horses, sheep and hogs, improve well on them. I think them excellent for sheep. They appear to be well calculated for villages, where land is high, and the occupants wish to obtain the most possible feed from a little land. I consider the root culture as of great importance, and increasing rapidly.

The Italian wheat did well, better than any other kind. I sowed two bushels, and some of it lodged, and did not fill so well, as the ground was too rich. However, I got forty-five bushels of excellent clean wheat, weighing upwards of sixty-one pounds to the bushel. It sells freely for three dollars per bushel. I have ground a few bushels, and it makes better flour than I can buy. My son-in-law carried six bushels last spring to Pine Creek, Tioga county, Pennsylvania, and calculates on 150 bushels; and he informs me he could take five dollars per bushel it he would sell it. He means to sow fifty bushels this spring. It has done so well hitherto.

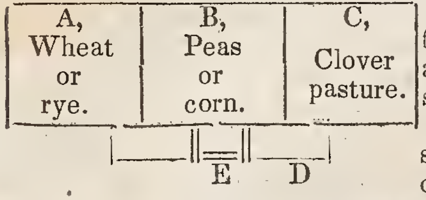
Potatoes, oats, barley, grass, &c. have done well last year. Apples were mostly spoiled before gathered the two last seasons. The winter has been soft so far. Some people have ploughed in January.

Cattle sell well. I sold a pair of four year old steers for 140 dollars, in September, after using them all the spring, and till that time. They were the short horned Durham in part. I think that half bloods of that breed answer our purposes for cows, oxen and for beef as well as any. Those cattle I sold had never eaten a bushel of grain. Last winter the yoke ate about 100 bushels of ruta baga.

Respectfully your humble servant,
J. Buel, Esq. URI TRACY.

Rotary Pig Pasture.

Jesse Buel, Esq.—Dear Sir,—The following is a description of a clover pasture for swine, which, in my opinion, where a situation is convenient for the same, with a warm soil, a portion of the farmers interest cannot be placed in a more profitable manner, than by having each successive year a fresh clover ley for his hogs.



A, represents a field of grain of one acre or more, well stocked with clover. B, a field of the same size of corn or peas. C, a clover pasture for hogs. D, a lane leading from the hog-pen.

The following year the lot A, will be the range for the hogs, and so on by a rotation of crops, the whole is constantly improving with the addition of the manure from the piggery. New improvements in rotation I frequently hear of, such as stoves, steam-boilers, &c. their success has induced me to send you the above plan of a Rotary Hog Pasture.

Yours respectfully. S. W. JEWETT.
Weybridge, Vt. 20th Jan'y. 1838.

EXTRACTS.

Experiments in Feeding Sheep.

[*From the French of Daubenton.*]

I confined, in a small space, two sheep, about twenty inches high, (the height of most woolled animals in France.) By way of experiment I caused the sheep to be fed, during eight days, solely upon grass newly cut, and weighed before placed in their rack. Care was taken to pick up, and place in it back again, all that the sheep let fall, and to weigh that which they would not eat in consequence of its being too tough, or because it possessed some bad quality. From this trial, frequently repeated, it appeared that a sheep of the middle stature eats about eight pounds of grass in a day. The same experiment, conducted with the same preciseness, in regard to the fodders of hay or straw, have proved, that a sheep of middling height likewise eats daily two pounds of hay, or two and a half pounds of straw.

In order to ascertain how many pounds of grass go to one pound of hay, I caused the grass to be weighed as soon as cut; it was then spread on cloths exposed to the sun, so that none might be lost, though at the same time well dried. Being thus converted into hay, I found its weight reduced to one fourth; eight pounds of grass had only given two lbs. of hay.*

Agriculturists know how many cart loads or trusses a field can produce; consequently they can judge how many sheep it can maintain in hay or in grass. They have a rule thence for proportioning the number of their sheep to the quantity of pasture and fodder they can supply them with.

Having determined the quantity of solid food essential to the good regimen of the woolled kind, I made other experiments upon these animals, in order to know at what time they should drink.

It is well known that they seldom drink when they feed upon fresh grass, but stand in want of water when fed on dry meal. Different opinions are pursued as to the proper time for watering them. In some countries they are taken to water once or twice every day; in others, not for one, two, three, four or even five days. By the following experiments I have endeavored to ascertain which of these regimens, so different from each other, is entitled to preference.

I shut up in a stable, in the depth of winter, a small flock, of which all the sheep were marked with a number. They were kept, night and day, without being suffered to quit it, and fed with a mixture of straw and of hay, without any other aliment. Each day a shepherd carried in his arms, successfully, some sheep out of the stable, to let them drink in my presence, out of a vessel guaged at different heights, and then took them back into the stable, when they had either drank or refused to drink.

By this method, I knew how much water the sheep had taken, when presented with it once, twice or thrice each day, or only once in two, three, four or five days. Most of the sheep in this little flock passed a month in the stable without drinking: their appetite was always the same, and they experienced no other inconvenience than that of thirst, of which they gave evident proof by running to lick the moist lips of those carried back to the stable on return from drinking.

The result of these experiments, which I cannot here detail, led me to conclude, that sheep, with no other nourishment than that of dry hay, and within reach of water, could pass days without drinking; but they would take a greater quantity of water the following day than if they had drank the evening before; this quantity increases to a certain degree if they have been deprived of water for many days together. They are then tormented with thirst, for they are then eager to get a drop of water; if they could find it in abundance they would drink too plentifully for their temperament, subject as they are to effusions of serosity, which produce mortal hydatides in the brain, and the rot, a disease no less fatal.

The best plan is to drive the flock every day to the pond, and to make it pass slowly, without stopping there: by this method it will be found that the sheep who really want to drink will be the only ones who will drink.

In countries where water is scarce, it frequently happens that the pond is far distant, and the flock cannot be driven to it without being fatigued; in this case they may pass many days without drinking; but when fed only on dry meal, it must not be delayed too long.

This aliment differs much from fresh grass, in consequence of the loss of moisture by drying; yet sheep take daily the same quantity of solid food, whether in grass or in hay. In the experiments before mentioned, I found their appetite perfectly equal, for they ate eight pounds of grass, or two corresponding pounds of hay, which I found to be the product of eight pounds of grass. The evaporation which is carried on during the making of the hay, takes off three fourths of the grass in fluid particles; thus the sheep which eats two pounds of hay is deprived of six pounds of liquid aliment, which it would have had by eating eight pounds of grass. It supplies a part of this deficiency by drinking about three pounds of water when fed upon hay; but this water is not in sufficient quantity, and posssesses not the same quality, as the liquid of the grass evaporated in drying.

There can be no doubt but this difference in regimen is productive of bad effects. I shall mention some fruits of it, which are indeed too evident and too frequent.

In countries where the snow remains upon the ground for one or two months, the cattle are reduced to dry fodder as long as it lasts; then the weaker sheep, and chiefly the lambs, the sheep of the second year, the pregnant ewes, and those in milk, languish and drop off. Shepherds denote this miserable state by saying, they melt their fat: they certainly grow very lean, and fall off in great numbers.

I have often reflected upon the cause of this evil, and the means of preventing it. After having prosecuted every inquiry I could think of, it appeared to me to arise solely from a change of diet too suddenly effected. In one day the sheep are reduced from eight pounds of grass to two pounds of dry fodder and three pounds of water. They are thus deprived, therefore, all at once, of three-eights of their wonted nourishment, and these three-eights composed the half of the fluid part of it.

According to my experience of the quantity of water taken by sheep, it appears that their drink can only supply one half of the liquid which grass contains more than hay. It would be dangerous to excite them to drink a greater quantity of water, because they are very subject to infiltrations. We must, therefore, endeavor to supply them with at least a small quantity of fresh food every day, in order to correct the bad effects resulting from dry meat.

The most sensible of these bad effects appears in the third stomach, composed in the interior of a great number of membraneous folds, detached from one another, although it is only from eight to ten inches in circumference when filled with air. During rumination the food passes from the throat into this third stomach, and spreads among all the folds. I have there found it very frequently parched, and almost withered, in many sheep which I have dissected.

This aliment, after having been ruminated, receives, in the third stomach of the sheep, and of other animals that chew the cud, a preparation for digestion, which latter takes place only in the fourth stomach. The aliment is dry in the third stomach, not only when the animal is fed on dry meal, which has not furnished sufficient liquid, but also when attacked by some disease causing too great heat, and consequently too great evaporation of the liquids necessary to digestion. In these cases, bad digestion, and the evils attending it, may be prevented by giving some green food at least once a day.

At all times when the ground is not covered with snow, sheep find upon it sufficient fresh food to render it unnecessary to give them any in the rack with their dry meal, in a bad season. I have often stopped in the midst of a flock, in fields half covered with snow, when no grass whatever was to be seen; the sheep, however, having their eyes near the ground, perceived the points of some leaves, and scratched with their feet to find more of the plant; they then seized it with their teeth, and sometimes pulled up the roots along with the leaves. But when the snow entirely covers the ground to a certain thickness, there is no other recourse than in the plants which are high enough to enable the sheep easily to remove the snow which covers them.

[The writer then proceeds to recommend a species of hardy cabbage, which might be raised without sowing or transplanting, to be cultivated for the winter use of sheep. It is to be remarked, that when Daubenton wrote, neither the turnip nor beet culture had been introduced into French agriculture. The latter now furnishes them an abundant and an excellent succulent food for the winter keep of sheep and other farm stock.]

---

* The loss in curing hay depends upon the species of grass, and the time at which it is cut. According to Sinclair's table, clover loses three fourths, timothy, when in flower, less than two thirds; and when cut in seed, but a little more than one half.—*Cond. Cult.*

Moneys received during the last month. Sums under five dollars not noticed.

THE CULTIVATOR--EXTRA.

ALBANY, MARCH, 1838.

N. Y. State Agricultural Society.

The society convened pursuant to adjournment at the City-Hall, in the city of Albany, on the first day of February, 1838. The President took the chair; Henry S. Randall, of Cortland, was appointed Secretary *pro tem.* After some preliminary arrangements, and for the purpose of enabling the State Agricultural Convention to be organized, the society adjourned to meet at the City-Hall on Friday, February 2d, at 10 o'clock, A. M.

City-Hall, Friday, February 2d, 1838.

Mr. Buel, from the Board of Inspectors, appointed at the last annual meeting of the society to examine and test the merits of new farm implements, reported that the board met in July last, and examined various farm implements, which were exhibited for their inspection. [For report see Cultivator Vol. iv. No. 6.]

The Treasurer of the society presented his annual report, which was read, accepted, and ordered to be filed.

Mr. Buel read a letter from Anthony Dey, of New-York, embracing copies of letters from J. W. Glass, of London, in relation to a new and improved process of manufacturing sugar from the beet. A copy of this communication was requested for publication, and is as follows:

New-York, 23d January, 1838.

Judge Buel,—Dear Sir,—I send you copies of four letters I have received from Mr. J. W. Glass, of "Clapton, London," on the subject of making *beet sugar.* I have supposed the best service I could *render the country,* was to transmit the information to you, and perhaps some one or more of the 20,000 subscribers you have, may find it to their advantage to correspond with Mr. Glass on the subject. Please make use of so much of the information conveyed as you may deem best to answer the desired purpose.

With great respect and esteem, I remain, y'r m. ob.

A. DEY, 63 Cedar-st.

—

Clapton, London, 1st Nov. 1837.

Anthony Dey, Esq. New-York:

Dear Sir,—Aware that you are a great promoter of scientific improvements, I beg leave to inform you, that a gentleman of my acquaintance has taken out a patent for a very valuable discovery in the manufacture of sugar from beet root, (and equally applicable to maple,) which, after paying to government the protectory duty of twenty-four shillings per cwt. he can afford to sell at half the price of West India sugars. By his process he can extract the saccharine from the beet all the year through, whilst under the process now employed in France, &c. it can only be extracted about three months in the year. He has been offered £70,000 sterling for his patent for England, but will not take less than £100,000. It has occurred to me, that if the soil of the United States be adapted to the culture of the beet root, a joint stock company might be formed in New-York, which would find favor with the public, and become a profitable speculation.

Your early and candid opinion on the subject will much oblige, dear, sir, respectfully, your most ob't ser't,

J. W. GLASS.

—

Clapton, London, 7th Nov. 1837.

Anthony Dey, Esq. New-York:

Dear Sir,—I refer to my respects of 1st inst. on the subject of the latest new invention for the extraction of sugar from beet root, and now beg leave to hand a few more particulars for your information, calculated, including the enormous duty of 24*s.* per cwt. levied by this government, from which I presume the process in America would be exempt.

The best French works are said to extract from one cwt. beet root six pounds of sugar and three pounds of molasses; by the new patent nine pounds of sugar is extracted, but little or no molasses. The French mode, therefore, gives six pounds of sugar at 6*d.* and three of molasses at 2*d.*: total 3*s.* 6*d.*; the new patent, nine pounds of sugar at 6*d.*: 4*s.* 6*d.* The average price at present, of West India sugar, is 37*s.* per cwt. Supposing the expense of extraction similar, the product would be 1*s.* per cwt. or 20*s.* per ton of beet, more than on the French plan. The raw material, no doubt cheaper with you, would cost 15*s.* per ton, therefore, any improvement causing an extra product of 20*s* per ton, would be 133 per cent on the raw article, besides the profit on the old French plan. The statement is the following:

Cost of 1 ton of sugar beet,	15*s.*
Manufacturing 12*s.* or say,	15*s.*
Cost,	30*s.*
Produce.—180 pounds of sugar, at 6*d.*	90*s.*
Less duty, at 24*s.* per cwt.	38*s.* 6*d.*
	51*s.* 6*d.*
Value of refuse, the pulp being used by paper makers,	2*s.* 6*d.*
	54*s.*
Cost,	30*s.*
Profit,	24*s.*

From these calculations I leave you to judge how far it might prove lucrative speculation, and I request your candid opinion of the best mode to carry it into operation in the United States.

Waiting the favor of your reply, I remain, dear sir, your most ob'nt servant, J. W. GLASS.

—

Clapton, London, 13th November, 1837.

Anthony Dey, Esq. New-York:

Dear Sir,—Referring to my respects of 7th ints. permit me to add a few words more for your consideration, in exemplification of the extract of sugar from beet root by the new process. The cost would not, without duty, exceed 2*d.* (4 *cents*) per pound.

Land in this country, ready for planting, rented at £6 per acre, stands, with cultivation, in not quite £10 per acre; the produce averages fifteen or twenty ton per acre. We can contract with growers in different parts of the country at 15*s.* per ton.

The question is, at what price can it be produced (*delivered*) in America? We have coals in Bristol, Liverpool, &c. at ten shillings per ton. Here we beat you. As to the value of the patent, my Bristol friends say that £100,000 may be too little for it! So much depends on the profit to be made by it, the security from invasion, and the mode of payment, I should think it would be a splendid thing for America; and waiting the pleasure of your advice, I remain, respectfully, dear sir, your most obd't servant, J. W. GLASS.

The invention would be equally applicable to the maple, or even the sugar cane.

—

London, 8th Dec. 1837.

Anthony Dey, Esq. New-York:

Dear Sir,—I am on the point of concluding the formation of a joint stock company, for the extract of sugar from beet root, alluded to in my former letters, with a capital of three hundred thousand pounds, one-third of which goes to the patentee, a part in money, the rest in shares. I have already explained to you that this sugar can be produced here, paying 15*s.* per ton for the beet root, at four cents per pound; and as the raw material may probably be grown cheaper in America, there may be an advantage; and hence the patent of discovery may be found quite as valuable there, as it is here. There appears to be a great many in, as the last quotations from New-York give New-Orleans sugar, wholesale, at 8½ to 9 cents, and lump 14 to 16 cents.

I look with some anxiety for your opinion on the subject; and remain, dear sir, your most obd't servant.

J. W. GLASS.

Mr. Duane, of Schenectady, from the committee to collect statistical facts in relation to the silk business, stated, that the chairman of the committee, Judge Spencer, was absent from the United States, and asked further time to report, which, on motion of Mr. Baldwin, of Onondaga, was granted.

On motion of Mr. Buel, it was

Resolved, That a committee be appointed to confer with the members of the legislature, and particularly with the agricultural committees of the two houses, on the expediency of making an appropriation of public moneys in aid of the improvement of our husbandry.

The chair named, as the above committee, Messrs. J. B. Duane, of Schenectady, A. McIntyre and J. Buel, of Albany, J. J. Viele, of Rensselaer, and A. Van Bergen, of Greene.

On motion of Mr. Allen, of Erie, the president and secretary of the society, were added to the committee.

On motion, Messrs. Duane, Buel, and Van Bergen, were appointed a committee to report to the society names of officers for the ensuing year.

Mr. Duane, from the above committee, reported the names of the following officers, and the report was unanimously adopted, viz:

JOHN P. BEEKMAN, of Columbia,	*President.*
Anthony Van Bergen, of Greene, W. A. S. North, of Schenectady, Archibald McIntyre, of Albany, Alexander Walsh, of Rensselaer, Harvey Baldwin, of Onondaga,	*Vice-Presid'ts.*
J. Buel, *Corresponding Secretary.*	
John Walsh, *Rec. Secretary.*	
Caleb N. Bement, *Treasurer.*	
John Townsend, of Albany, Jesse Buel, of do. Alexander Walsh, of Rensselaer, H. D. Grove, of do. L. F. Allen, of Erie,	*Exe. Committee.*

Mr. North introduced the following preamble and resolutions, which were adopted:

Inasmuch as the object of this society is the improvement of agriculture in all its branches,—and as the speediest way of diffusing agricultural knowledge, is by eliciting from its members, whatever of experience they may have gained in those departments of farming, to which they have particularly turned their attention; therefore,

Resolved, That committees of two be appointed to furnish the society, at its next annual meeting, reports on the following subjects:

1. On farm yard management, as it relates to the wintering of cattle and the augmentation of manures. [Committee, Messrs. North and Duane, of Schenectady.]

2. As regards the feeding and management of sheep in winter. [Committee, Messrs. Rotch, of Otsego, and Grove, of Rensselaer.]

3. On the most approved method of stall feeding oxen and other neat cattle. [Committee, John Sanford and Dan. Brandley, of Onondaga.]

4. On the best vegetable or root crops for feeding cattle, and the best manner of cultivating the same. [Committee, Messrs. Buel and Bullock, of Albany.]

5. On the most profitable mode of fattening hogs and rearing swine. [Committee, Messrs. Bement, of Albany, and McDonald, of Washington.]

6. On converting weeds, green crops, and vegetables into manure, and forming composts, and the application of different kinds of manure to different soils. [Committee, Messrs. Ball and Walsh, of Rensselaer.]

7. On the effects of lime and its application to different soils. [Committee, Messrs. W. Gaylord, of Onondaga, and J. J. Viele, of Rensselaer.]

8. On meadow and pasture lands, and the best modes of renovating them, and of seeding down lands to grass. [Committee, Messrs. L. F. Allen, of Erie, and Matthews, of Cortland.]

9. On the proper time to cut timothy and clover, and the most approved method of curing the same. [Committee, A. Van Bergen, of Greene, and S. Towsley, of Onondaga.]

10. To digest a plan for the improvement of our common roads. [Committee, Messrs. Cheever, Buel and McIntyre, of Albany.]

The society then adjourned to meet at the Assembly Chamber, at 4 P. M.

Assembly Chamber, 4 *P. M. Feb.* 2.

The President delivered the following

Address.

Gentlemen:

Having been selected by your partiality, more than my fitness, to fill the office of president of this society for the last year, it is made my duty at the expiration of the term to address you. In doing so, I could wish to make it more than a simple matter of form. Were my abilities equal to my inclination, I would throw around the great subject we have met to discuss and improve, the most captivating eloquence, and the most convincing argument. But, gentlemen, I make no pretensions to the first; and, being a farmer by choice, if I can impart any interest to my subject, it is in the lessons I have drawn from my own practical observations in husbandry.

On an occasion like this, two years since, we were favored with an address from a most worthy and liberal minded member of this society, but who is now no more, on the necessity of educating our young men for farmers, and thus to make them more fully appreciate the responsibilities they owe to the advancement of their profession, to their country, and to society. On a similar occasion last year, the subject selected for our consideration was, a history of agriculture from the earliest time until that period. Both were topics important and interesing, and peculiarly calculated to awaken our attention, deepen our impressions, and make us better and wiser men. I could wish to impart an equal interest to the subject I have chosen; and that is, what ought to be the next step in the farther improvement of agriculture.

All who hear me will doubtless agree with me, that as husbandry was the first instituted, so it is still the most important pursuit of man, and therefore, whatever tends to its improvement, is another advance towards the attainment of a common blessing. All will likewise concede, that ours has heretofore been more a laboring of the hands, than the head; and that, whilst we have literally fulfilled the command to "earn our bread in the sweat of our brows," we have not opened the sources of knowledge, and called science, which has shed so much light upon other subjects, to the aid of labor, but have been willing to plod on content, in too many instances, with the annually reduced pittance we have gleaned from the soil. But, can it be that science, which affords us so much intellectual gratification, and has opened so many fountains of wealth; which has made us more conversant with the innumerable works of the Deity, and enlarged both our enjoyment and capacity ten thousand fold—can it be that she is forbid by the farmer to enter his domain, lest she should teach him lessons that may mortify his pride, or alarm his prejudice? Or will he assume the ground that agriculture cannot be improved; that we have arrived at a point beyond which the products of the soil cannot be increased, and we must be content with our husbandry as it is; that farther innovation cannot advance it; and that however much the mind has done for other pursuits, ours admits of no deeper research nor clearer investigation? Gentlemen, could I be persuaded to adopt this opinion, I would erase my name from the roll of the members of this society; for to me the great charm of agriculture is the hope of its advancement. I cannot think that a God of infinite wisdom, who gave the immortal mind to man, with powers to look into the world around and above him, and by his intellect to make all in the universe subservient to his interest or his wants—has decreed, that in the cultivation of the soil, which contributes so largely to his support and happiness, man is forever to follow only the dictates of instinct, and not the lights of reflection and reason. No. Our mental faculties are the noblest part of our creation; they give us command over the beasts of the field and the fowls of the air; they enable us to comprehend and know God as the Author of our existence, and the giver of our bounties; and it is the improvement of them only that can make us acceptable in the sight of Him, who is himself both omnipotent and omniscient. The brute may perish, and the works of our hands crumble by time, and be lost in the lapse of ages; but the immortal mind, enlightened by the study of the past, and looking with hope to the future, stretches forth her sleepless energies to understand creation as it is, and ultimately take home with her the sublime pleasure that the acquisition of knowledge has imparted. Cannot then the mind be made to operate upon the stubborn soil, to make her more abundantly yield her increase? Most assuredly it can; if we but call to our aid all the light which science has shed, and is shedding, and diligently and systematically apply it, our callling will not lag behind other avocations in the steady march in improvement.

When we take a view of the works of Deity, we are lost in astonishment at the comprehensiveness of the mind that conceived, the power that created, and as far as we can follow them, the beautiful and exact laws that regulate and control the whole machinery of animate and inanimate nature. We see *order*, the first law, the great law that governs equally the movements of the world, or the formation of the most insignificant insect. If we go farther, we see it is given to finite man, when he makes one branch of the works of the Almighty a subject of study and reflection; if he first looks back and sees how far others have gone, compares their ideas with his own; takes constant advantage of the thousand arguments that nature is beautifully and daily unfolding to his view—if he arranges his materials and gives a systematic operation to all his movements and thoughts, persevering in his plan, and never doubting of ultimate success,—we see him at last bring order out of confusion, and what was before slighted because it was not understood, now becomes of importance as we are made acquainted with its uses. It is to labors like these, that we are indebted for our knowledge of astronomy, chemistry, geology, botany, languages, &c. &c. and all the advances in the sciences and arts that contribute so much to the happiness and intelligence of civilized man. But to an uncultivated intellect, that does not avail itself of the labors of the past; where the mind has not been expanded by reading and reflection; whose notions are of one kind to-day, of another kind to-morrow; where conjecture supplies the place of arranged facts, and prejudice is a bar to a just elucidation of the laws of reason and nature; where all is crude, confused and mixed up—the good with the bad, the useful with the useless, sense with nonsense, and reason with folly—and united, too, as they are, with a boastful desire to give opinions to the world, as the emanation of reason, and the clear results of a long experience; what else must follow, but that darkness will continue to cover the land, and gross darkness the people. These last observations apply with a peculiar force to the past and present state of our farming operations. Although we have cultivated the earth for thousands of years, we have yet no arranged system of action, and the beautiful law of order, which God has stamped upon this as one of his works, we do not yet understand; for we have not yet learned to reason from cause to effect. To be sure we sow in spring and reap in autumn, and gather into barns to supply our wants, and those of our flocks. But did not our father Jacob do so? did not the patient Job do so? and likewise Boaz, the kind-heated husband of Ruth, at least five thousand years ago? And what has been done for the advancement of agriculture, between these generations and ours? It is a fact, gentlemen, that something like improvement in farming has taken place only within the last fifty years. It commenced in England and Scotland, and these countries have for some time experienced the benefits of what they call their improved husbandry. Within that time they have doubled their products, but in one important point they have a manifest advantage over us; that is, they can employ three hands as cheaply as we can one, and have their board in the bargain. Still, although much has been done there to increase the products of the earth, yet, in my humble conception, radically and permanently to improve, they must adopt another and better plan, and instead of raising farmers by instinct, they must be reared by education. Instead of a man of any age turning farmer, and at once ignorantly triumphing in his success, and boasting of his knowledge, he must be taught by a dear-bought experience, that he has undertaken a business he does not understand, because he cannot compete with one who in early youth has had his mind expanded by both scientific and practical culture.

We have all seen the absolute necessity that the lawyer, the physician, the manufacturer, and the artizan, should go through a regular course of study, reflection and practice, to fit them for the proper discharge of their respective duties. Think you that in the noble science of farming—for science I will call it—less of education, study and reflection are necessary? No, gentlemen. Depend upon it, if we are to place husbandry upon a stable basis—if we wish to see this broad and fertile land covered with the habitations of plenty, and containing a happy and prosperous people, we must give an early direction to the human mind, to enable it to comprehend and fully grasp the subject. We must come back to elementary principles, and ascertain the different ingredients of which the earth is composed; we must understand their structure, combination, and uses, and what acts upon each with most effect for the benefit of man. These are studies sufficient to engage the undivided attention from early life to its close; and even if we should fail in our first attempts, still we would ultimately place husbandry upon so firm a basis, that nothing would be wanting to secure the full fruition of our labor, but the smiles of a beneficent Providence. To accomplish these desirable objects, a young man must first have a good school education; he must then be taught chemistry, geology, and botany; have a knowledge of mathematics, and perhaps mineralogy, with so much of entomology as is necessary to guard against the mischievous effects of insects. These are some of the hand-maids to the knowledge of agriculture, which, to insure success, must be carefully cultivated.

To lay the foundation in early life for an agricultural edcuation, what would be so useful as an agricultural school, where not only these, but many other collateral branches would be taught, and from which, if a young man graduated, it would prepare him not only for usefulness in life, but accomplish him as a man of science and a gentleman. It would open his mind to view agriculture in a different light from the generality of farmers. He would understand how cause operated to produce effect, and how he could give most efficiency to his labors. From mathematics, the science which contemplates whatever is capable of being numbered or measured, it would lead him to a correct knowledge of practical mechanics, the application of the principles of power and land mensuration. From chemistry, the science which enables us to discover the peculiar properties of all natural bodies, either in their simple or compound state, he would learn to analyse the different kinds of soil, ascertain wherein they differ—what combinations are the most useful, and, if possible, in what the principles of fertility consist, and what must be added or taken away to make barren or degenerate land more productive. The doctrine of manures cannot be understood without a knowledge of chemistry; and it is a subject so extensive in its application to farming purposes, that it must be the A, B, C, of the farmer's education. Geology, and, if necessary, mineralogy, would teach him to discriminate between the different kinds of substances the earth is composed of, and give him a correct knowledge, not only of what the surface of the soil consists, but what is buried beneath it. Botany, the science of plants, or that part of natural history that relates to vegetables, would teach him to ascertain their different uses—discriminate the exhausting plants from those that are less so—the locations most favorable to their growth—the seasons for their production and reproduction—their laws of generation—the alternation that ought to be observed for the best development of their powers, so that whatever plant was cultivated, it would be the best and most valuable of its kind. These are some few of the studies, upon which we have entered somewhat into detail, that should be taught in such an institution. The mind, however, would not only be regulated and instructed, but habits established quite as useful to the full development of the bodily powers. Would nothing, think you, be gained by instilling principles of virtue, of regularity and order—by forming habits of industry, teaching a correct moral deportment, and discountenancing idleness and vice? Permit me here to particularize and point out in a single instance the benefits that would follow the adoption of one simple rule—that is, keeping farm accounts—entering the debtor and creditor account of the farm, and making out an exact statement of its profit and loss. Or you may go farther, that of each lot and each animal. If you ask what special benefit would flow from the practice, I answer, you can at once calculate the relative value of your farm, either in whole or part—the expenses of its cultivation,—the annual cost of your household—the profit on each lot or animal, and as a general result determine whether you are gaining money or losing it. If making, to continue; if losing, to quit before bankruptcy follows. Besides you may graduate your family expenses by it, and at one glance you may ascertain your exact standing in a pecuniary point of view in the community. Why does a merchant keep his accounts but to regulate his business by striking his balances? Ought not the farmer to be equally particular? The time will come when he too will make his regular daily entries as necessary to the successful prosecution of his business.

We have dwelt on this one item, simply as an elucidation of the general argument in favor of education; but suppose, to quote the language I have used on a former occasion, a State Agricultural School, under a proper course of instruction, to contain two hundred students, and a course of studies to last three years. It would send each year, after the termination of the third, nearly seventy young men, so educated into the different sections of our state. Their knowledge of theoretical and practical farming would be generally diffused; and continue this number for many successive years, it would give thousands of the best farmers, scattering them through every portion of the state. And here let me ask, who is so much of a skeptic as not to believe, that agricultural knowledge would be increased by so great an accession; and, in consequence, agricultural products be prodigiously multiplied? But, this is not all; our school would not only send her missionaries of intelligence and industry through this state, but all her operations—so far as competent professors could discharge their duty of instructing or experimenting—of collecting, comparing and examining all that was most familiar or rare—ornamental, useful, or profitable, in each of their peculiar departments—in a short time we would have a farm and collection, which would vie in extent and appearance, and much exceed in usefulness, the far-famed gardens of London or Paris. Probably at no time in the history of our state, could an agricultural school be founded under as favorable auspices for ultimate success, as at present. By the establishment of agricultural journals, a taste for that kind of reading has been created; our citizens are alive to farther improvements, for they have heretofore felt the want of them. The efforts made and making to give a more thorough school education to our population—the ability of our citizens to contribute whatever may be required to carry the object into effect—the easy transmission of produce through every portion of our state by our rivers, roads, canals and rail-ways—the facility of communication with New-York, one of the best markets in the world, all are so many aids to the successful completion of the plan.

Should this school go into operation, and carry out the great principles of its founders, the time will, must come, when every citizen will be proud of it as a state institution; when those who have been its friends, will gladly come foward and claim the honors to which they will be entitled, and the present state authorities will take a pride to date its commencement as coeval with their administration of power; for, besides being a test farm systematically managed, its manufacture and collection of the various farm implements, its specimens of geology, mineralogy, and botany; the exhibition of its animals; the order and regularity of all its operations in husbandry; the circulation among our farmers of useful intelligence collected there, either from practice or experiment; the aids it will give to our agricultural journals, and above all, the young men it will yearly send out to every portion of our country to vivify by their intelligence, and fructify by their industry, whatever place they settle in; will be so many claims to popular favor, for they will be constant and living evidences of its great usefulness.

On motion of Mr. Fry, of Montgomery,

Resolved, That the thanks of the society be presented to the president, Dr. Beekman, for his very able and highly interesting address, and that a copy be requested for publication.

Mr. A. Walsh, of Rensselaer, from the committee to report on the subject of horticulture, and the household arts, presented the following report, which was read and adopted.

Horticultural Report.

The committee appointed to "inquire into the necessity and importance of an increased attention to Horticulture and the Household Arts, as intimately connected with the improvement of Agriculture," beg leave to report—

That on investigating the subject in pursuance of the duty assigned them, they have become deeply impressed with a sense of its importance; and they regret that the necessary degree of brevity will only permit them to touch the mere outlines of some of the most prominent arguments which present themselves in its favor.

By the term horticulture, they understand that portion of agriculture which embraces the labors of the garden—the cultivation of vegetables, fruits, &c.

It is strange, as well as lamentable, that though this appears especially designed, by the Creator, as the first and most important employment of man, yet while every useful art is improving and perfecting by the light of science, this most valuable art should be left to grope in darkness—its value remaining unknown and unappreciated. All, therefore, that your committee can do is, to endeavor to awaken the public mind from the apathy under which it sleeps on the subject; to remove the strange prejudice which exists against it; and to open a way for the reception of those spontaneous rays of light which present themselves from luminous sources.

And here, at the outset, your committee feel under peculiar embarrassments; for what arguments can be offered, to awaken to understanding the mind of him who can discover no profit, or receive no pleasure, from a well cultivated garden.

It is in vain that Infinite Wisdom has exerted its utmost skill in forming, perfuming and painting flowers to decorate his path, and sweeten the toils of life, if the same power has denied him a mind susceptible of the enjoyment. The depravity of public taste, with respect to gardening, has given currency to a common saying, that "good farmers seldom have good gardens," but never was a sentence more in opposition to the truth. It is so completely so, that if we look on even a remote corner of a farm, and see it well fenced and cultivated, we may almost rest assured that on visiting the dwelling of its owner, we shall find a neat, tasteful and well stocked farm garden. Indeed, so intimately connected are the moral and social virtues, with a taste for admiring and improving the beauties of nature, that we can rarely find one without the other. There is, perhaps, no other earthly subject so well calculated to awaken and expand every faculty of the mind, and fill the soul with pleasing admiration, as a garden of culinary plants, fruits and flowers, where art and science have done their duty in assisting nature.

Horticulture, both as an art and as a science, has undergone great improvements, in several countries in Europe; and it must be painfully mortifying to an American of patriotic feelings, who is acquainted with the subject, to see respectable foreigners, in passing through our country, notice the almost total neglect of this beautifying, and moralizing branch of social economy.

The mode in which agriculture, if it can be so called, has hitherto been conducted, had its origin, no doubt, in the circumstances of the early settlers of our country. Those pioneers were not in situations to indulge refined taste; being only enabled by their utmost exertions to procure what would barely sustain life; and pecuniary necessity compelled them to cultivate such simple articles as they could dispose of, in mass, for immediate relief, and the state of society afforded no market for fruits or garden vegetables. This state of things established a distaste for any thing to gratify the eye or the palate, beyond bare necessity; and this distaste has continued with little improvement to the present time.

But a few, among those engaged in agriculture, have discovered that, by rational improvements in the system, not only the same ground, with the same labor, might be made to double, and even quadruple its former productions; but that horticulture, tastefully and judiciously managed, is calculated to improve the mind, to excite and expand the intellectual faculties; and especially to increase wealth, at least as much as any other branch of agriculture.

The ancient prejudices against horticulture, are now beginning to be overcome, by the convincing evidence of successful results, and some of the more industrious and thinking farmers begin to see that a well selected assortment of choice fruit yields a greater profit, than perhaps any other crop from the same ground; that the choice new garden vegetables cost no more in cultivation than the most coarse and common, while they add comfort and healthy variety to the table, and lessen the heavier expense of animal food. They begin, in a few instances, to find that the value of a farm depends not so much upon the number of acres as upon its judicious mode of culture, and its productiveness. They see that a handsome and convenient, but not a large and extravagant dwelling, surrounded by fruit and ornamental trees, but more particularly a well stocked farm house garden, not only increase their comforts and respectability, and even their wealth while in possession, but if they wish to sell, attracts the notice of purchasers and enhances the price.

Our forests abound with maple, elm, ash, and other elegantly formed ornamental shade trees, which we would recommend our agriculturists to plant along the road side, bordering their homesteads. They will thrive in almost any situation, and add beauty and value to their possessions and improve the general aspect of the country. "We never pass a tree which has been planted and nurtured by man, but we feel gratitude and respect towards the hand that done it." The cultivation of the Mulberry and the growth of timber, particularly live oak, locust and cedar, deserve the highest consideration; such trees being required, and commanding a high price for ship building, and in our growing manufactories.

In short, from the palace to the humblest cottage the business of horticulture, when carried to the perfection of which it is susceptible, appears to your committee, to be calculated, above all other branches of industry, to improve the mind and manners; to increase and multiply the comforts, and promote the wealth and respectability of the community.

We would therefore recommend to all, to use all justifiable exertions to excite a more general taste for horticulture, and to promote a more thorough and generally diffused knowledge of its principles and practice.—To this end, we would recommend, that those who have any knowledge of the subject would communicate it to those who have none, and that more general attention should be paid to the various periodicals which are published and publishing on horticulture, and subjects connected with it—and they would also suggest, that should the honorable legislature think proper to lend their aid to the subject, as they have done in some of the other states, much might be effected by their employing and paying some suitable person to write or compile a text book, as a manual for the use of farmers and mechanics, on horticulture and the household arts, and particularly on the subject of the growing of silk.

With respect to the "necessity and importance of the household arts," your committee are fully convinced, that, in the thriftiness, and good regulations and consequent happiness of society, as much depends on good housewifery as on good husbandry. It is a common saying, that "the man who would thrive must ask his wife." These arts are not only more numerous and complicate, but susceptible of even greater improvements both from the aid of science and the dictates of common sense, than those which belong to the outdoor economy; and they principally belong to the female department. The culinary arts alone embrace a more extensive and complicated system of knowledge than probably appertains to any one trade in the compass of the mechanic arts. On that system depends, not only our comfort and satisfaction in eating and drinking, and our health in the choice and preparation of food, but our prosperity in the economy of its management. The important business of the dairy depends almost entirely upon the skill of the housewife. But a few years ago they were the sole manufacturers of most of our clothing, and still a portion of it depends for its formation on their ingenuity and industry; even in the cottages of the poor, we may often admire the talents of the industrious housewife where

> "The mither, wi' her needle an' her shears,
> Gars ould claes look amaist as weel's the new."

But these important domestic arts, on which our comforts and prosperity so much depends, are too much neglected and despised. It is the duty, and ought to be the pride of every mother in America, to teach her daughters, first the most substantial and all important arts of good housewifery; and next to call forth and excite to action all their surplus ingenuity, diverting it into such channels as will elevate our national character, and by lessening dependence on foreign nations, promote the independence of our own.

It is natural, and perhaps proper, for females to delight in finery; and to this end, nature has invested them with sprightly intellects to invent, and delicate fingers to construct it. But instead of availing themselves of these precious gifts of nature, our females generally appear to have almost wholly lost sight of, or never to have possessed a spark of that national pride which would prompt them to turn those talents to their own advantage. It would be deemed an insult to say that they have not as much inventive talent and refined taste as the females of France, and yet they appear to have cultivated a spirit of emulation to outdo each other in servile dependance on French fashions and French finery; (which fashions and finery do not arrive here, until cast off in France, so that the summer dresses of that country become the unsuitable winter dresses of this,) until by extravagant importations of those articles, added to the immense amount paid for silk beyond our means, we have continued to plunge our country into a state of pecuniary distress, from which it will not soon be extricated. How much more independence should we display if our females would employ their leisure hours, and exert their ingenuity, in constructing ornamental dresses suited to our climate, according with their own refined taste, and let the French follow their own fashions, or servilely copy ours if they please.

Those of our young females who are destined to receive what is considered a polite education, are by the present national public taste, studiously kept ignorant of any thing which can contribute in the slightest degree to the future benefit of their families or themselves. Thus, in most of the more opulent families of the community, those important arts on which domestic comforts so greatly depend are left to the sole possession and management of domestics.

It is, therefore, of the highest importance, that females who are coming on the stage of action, should receive such education as should fit them in a greater degree for the important stations they are destined to fill.—Without rejecting what are justly considered polite accomplishments, every female who is to become the head of a family, ought to have a thorough theoretic and practical knowledge of all the arts which appertain to cookery and systematic household arrangement. This knowledge would be greatly enhanced by an acquaintance with some of the natural sciences, particularly chemistry. Indeed, so important is a smattering of that branch of science, in every part of household economy, especially in the management of a dairy, that no female ought to be considered well educated without it.

But there is one branch of the household arts which your committee would strongly recommend.

By the aid of labor saving inventions, females are relieved from a great and tedious part of their former labors, and they have consequently now a considerable portion of leisure.

There are many little household arts, by which they could manufacture little articles, which would command fair prices in market.

Many of these arts have been introduced by necessity in other countries; and a little attention to the subject would render them sources of profit here.

There is one which we would earnestly recommend, as paramount to, and probably superceding the necessity of any other. This is the growing and reeling of silk. This is, perhaps, as pleasing an employment as the human faculties can be engaged in. It is inseparably connected with a branch of horticulture, and will need some male assistance in cultivating the Mulberry trees, and erecting necessary fixtures. But the growing the silk is the appropriate work of women and children. It is periodical, leaving long intervals of rest; and the reeling is a light, easy and social employment, peculiarly calculated for delicate female fingers.

The profits arising from this business will be equal, if not superior, to those of any other branch connected with agriculture; and will need no other time devoted to it in the female department than is now devoted to leisure. It is now the heaviest item of our importations, and will find a sure market among ourselves, or will command a high price in return for its exportation.

Your committee, therefore, would most fervently urge that a proper attention to horticulture, effecting by art and science all the improvements of which it is susceptible, and similar attention to the household arts, as of the highest national importance, particularly the growing of silk, affording the surest guarantee to the independence and prosperity of our union.

Your committee would also strongly urge the importance of County Fairs, as one of the most efficient means of improving both agriculture and horticulture, and the household arts, by awakening ambition and exciting a spirit of emulation in both sexes. These Fairs would, as they have already done in many places, call forth new displays of ingenuity—choice products of the farm and of the garden, in needle work and miscellaneous subjects; and we think the legislature would do much to exalt the national character by appropriating a small fund to each county, that may have its rural society for the support of such Fairs.

All of which is respectfully submitted.

ALEXANDER WALSH, *Chairman.*

Mr. W. A. S. North, of Schenectady, read the following Report on the subject of Neat Cattle, which was accepted.

Report on Neat Cattle.

In drawing up the following remarks in pursuance of a resolution of the Society, passed at their last meeting, your committee have had some difficulties to encounter, the greatest of which has been the want of that personal communication with each other, which the importance of the subject demanded, and which has compelled them to put off the drawing up of the Report to the last minute. Of the many subjects relating to rural economy which were submitted to the different committees at that meeting, there is none more immediately interesting to the great body of agriculturists, than the one intrusted to your committee, to wit, the present state and future improvement of Neat Cattle. It is a subject which appears to be less understood, and to have received less attention, than any other, "and is most completely identified with our agricultural prosperity and with the comforts, and the very continuance of life."—That this kind of stock constitutes a great proportion of the wealth of the country may be inferred from the fact, that our state alone, according to the census of 1835, contains 1,885,771 cattle. It will hardly be expected that your committee should go into a particular history of all the known breeds of cattle, and of all their peculiar properties. Such a course would do in writing a treatise on cattle, but in the present case would only tend to confuse the mind of the inexperienced breeder. Your committee therefore have thought it advisable to confine themselves in the performance of the duty assigned them, to giving a short general description of the most common kinds of cattle among us, as well, those imported as our native stock, noting their good and bad points, and by stating the disadvantages and losses attending a careless and unskilful course of breeding, rearing, and feeding, endeavor to get up a spirit of reformation and improvement among the agricultural population; thereby increasing their wealth, and adding to the subsistence and comfort of all classes of the community; and if, by means of our report, and those which shall be read here to-day, the farmers could be induced to employ more capital, and to exert more care and skill in all the various branches of agriculture, and particularly to the one under consideration, it would greatly add to the productiveness of their farms, and their wealth. Many books have been published, detailing the great improvements made and still making in England in neat stock, but they cannot be expected to be in the hands of our farmers, and it will be our aim in this report, in some degree, to make up this deficiency, by endeavoring to show wherein our native stock are deficient, and recommending to them a better and more profitable course of breeding. To begin then with the most numerous and least profitable breed, the native cow.—"They are a mixture of every breed, and the intelligent and observing breeder, sees in them traces of almost all the English varieties, such perhaps as they were before science and attention had improved them, such as might offer to the American breeder the original materials of their most improved and valued stock, but requiring more time and perhaps more talent, skill and attention, than the American farmer would be willing to bestow on the subject, and yet necessary to enable him to arrive at the same results. This mixed breed are not very celebrated for any thing; some of them are good milkers as far as quantity is concerned, but as to quality of the milk and aptitude to fatten, they generally fail. Their calves are of diminutive size, rarely giving more than 20 lbs. per qr. when killed, at four weeks old; and if reared, of slow growth, seldom coming in till the third year, and then requiring two or three years more to give them standing and character, such as it is, in the dairy. As to their characteristic marks, they are small, short bodied, thin and coarse haired, steep rumped, slab sided, having little aptitude to fatten, or to lay the fat on the right place. There is another class of the native cow, although distinctively marked, (as the horns are wanting,) yet this want will hardly entitle them to be considered a distinct breed, deserves to be mentioned in the enumeration of the native breed. Descended from the Galloway or Angus cattle, a long while ago, they still retain among all the crosses to which they have been subjected, some of the marks and good points for which their ancestors are still celebrated—that is to say, they are a docile, thrifty, hardy kind of animal, with much the same faults, as to form, of those above described, though perhaps more compact, shorter in the leg, a middling thick hide, and withal easier fattened. They are few in number compared with the horned cattle. There is one other species of the native cow, to which it is only necessary to direct your attention, as they are nearly as much celebrated in the sandy tract of country about Albany and Schenectady as the improved short horns themselves, the one for their beauty and good points, the other for their homeliness and bad points. They are peculiar to the sandy soils of our country, running wild in the woods in the summer, and picking up a miserable subsistence in the barn yard in the winter. They are a long legged, raw boned, narrow hipped, sharp backed, steep rumped, slab sided, coarse haired, worthless race, and exactly answer the description of those kine that came up out of the river of Egypt in the time of Pharoah—"They are poor, ill-flavored and lean fleshed, such as were never seen in all the land of Egypt for badness." It is not likely that any improvement will be made in this kind of animal, the nature of the soil, the habits of growing the coarser kinds of grain, the foddering of straw in the winter, and pasturing in the woods in summer, peculiar to the inhabitants, (they ought not to be called farmers,) of the Pine bush, will for years to come prevent any permanent amelioration of their condition. If at any time, the spirit of improvement should enter into the calculations of these people, they might by judicious crossing, and a plentiful supply of roots and vegetables to their stock for a great part of the year, attain to something more respectable in this branch of business. This then appears to be the character, and these the qualifications of our native stock." Notwithstanding their defects, "most valuable selections might be made from them, and these crossed by bulls of the improved breed, would furnish perhaps the most useful stock for the practical man, who was not prepared to pay the high prices inseparable from imported stock." And it will be advisable to select cows, either from stock feeding in the neighborhood, or from those sorts that are best calculated for the nature and situation of the soil. The grand secret of breeding, is to suit the breed to the soil and climate. It is because this has not been attended to, that those breeds which have been invaluable in certain districts, have proved altogether profitless and utterly unworthy of culture in others. Let that breed then which is most profitable and best suited to the farm be ascertained, and having succeeded in this, strive to improve it to the utmost, by selecting and breeding from those which to beauty of form, unite the more essential qualities of possessing kindly skins, of weighing most in the valuable parts, together with a disposition to lay fat on the best points, as well as to fatten in a short period of time. The term "kindly skin" means a soft mellow skin, yet firm to the touch, and is as different from the hard, dry skin of some cattle, as it is from the loose, flabby skin of others. The sense of touch, or the art of judging of the disposition to fatten, has been brought to such perfection, that any well informed breeder can, on examining lean beasts, tell with tolerable certainty in what parts they will or will not fatten. The improved short horns are in all respects the most profitable species of animal to cross with the native cow in situations where the soil is rich and luxuriant. They are good milkers, quick feeders, arriving at early maturity, and affording the greatest proportion of good meat to its offal, from the thickness and softness of hair with which this breed is covered, they endure without suffering the severity of our weather; but to the full development of all their properties, and to obtain their most valuable returns they should be well cared for and fed upon a full bite of grass. That this valuable breed of cattle have not been more generally sought for as a cross with our native stock is owing in some degree, to their intrinsic value in comparison with others. It is true the first cost of pure bred animals is high, but when it is considered how extensive is the influence of a bull, and how many improved animals may be yearly obtained by his services, the remuneration is most abundant. A very fine pure bred bull may be obtained for from two to three hundred dollars, and such an animal at three years old, may without injury to himself wait upon fifty cows. In those neighborhoods where such an animal is kept, the half bred yearlings bring from ten to twenty dollars, and in some cases thirty dollars. Our farmers only want to believe this fact to act upon it. But how make them believe it? Why let those gentlemen whose tastes, whose consideration for the farmer, whose love of doing good and whose means are sufficient, purchase such an animal, and allow his neighborhood a discriminative use of his services till conviction followed the evidence thus brought home to them. This has been the practice of your committee, who have allowed the industrious and inquiring farmer the use of their bulls for a few years past, without collecting the amount professedly charged for their services, and they now generally pay the service fee cheerfully, and the work of improvement is in our sections of the country rapidly going on. Another reason why the improved short horns are not more eagerly sought for by the great mass of farmers, is the idea that they require more food and will not keep so easy as the native cow. Now, if they pay better, and in proportion to the extra feed they require, and no one will deny that they do, this objection falls to the ground. The truth is, that as long as the slovenly style of farming of the present day prevails, as it does in too many districts of the state, this objection will continue to be urged. There is yet very little good farming or systematic rotation of cropping pursued, either by our large or small farmers. The land is taxed to its utmost as long as it will bear an average crop of any thing, and when completely exhausted, it is seeded down with five or six pounds of Timothy and Clover to the acre, and Oats or Buck Wheat, and if, as is generally the case, the grass is light, it is pastured until it recovers again in some measure by the manure dropped upon it, or till it is covered with a heavy growth of moss, which turned under in the right time will, after a fashion, enable it again to undergo the process of cropping. Until this system is abandoned, and more attention paid to keep pasture lands in better tilth, and the growing of root crops for winter fodder for neat stock, it is almost useless to attempt to improve the breed of cattle, or any thing else. Even the aristocratic race of the short horns in such cases would be compelled to knock under, and in process of time, by hard fare and inattention, would get back to the point from which skill and science, and care and attention first rescued them, and gave them their present elevated station among the brute creation. Let it be remembered, that a good bite of grass in summer, and generous feeding in winter, is necessary to the full development and profitable culture of the short horns. Where this cannot be had, and the land is light and subject to drought, the beautiful little Devon will best find its value, and though not so good a dairy cow, yet she is the source of the finest working oxen, perhaps in the world. The Devons have also a claim to quick feeding, and a maturity much earlier than any unimproved breed. They are said to be the Aboriginal breed of Great Britain, and are there highly valued, and make most delicate beef when fatted. On lands of the above character, the cross between the Devon bull and the native cow would no doubt succeed admirably. These two varieties, the Improved Short Horns and the Devons belong to different soils, and are suited to different purposes, and both are extremely valuable in the situations to which they are adapted. The Galloways are also a breed well fitted, by reason of their hardihood, kindly feeding, and much endurance to the severity of our winters, and the misery of our barn yards. They are a very handsome breed of cattle, straight and broad in the back, round in the barrel, and full in the rib, in which points they will compare with any breed. They lay their fat upon the most valuable parts, and though the feed be short, and the winters long, they will do well and thrive. The Ayreshire breed are also said to feed kindly and profitably, in districts where others could not be made to thrive at all, uniting to a greater degree than any other breed, the supposed incompatible properties of yielding a great deal of milk and beef.—They are new comers, but bring with them a good report, and if they maintain the same excellent character for the dairy in our warmer climate, which they have gained at home, they may become the favorite stock of the country, though it is more than probable that when transplanted from their moist climate and poor soil to our warmer climate and richer soil, they will lose their superiority as milkers, and begin to accumulate flesh. The Hereford and Holstein breeds are partially known, in this country, and what little is known is not much to their credit. The former is no milker, the latter gives abundance of milk, but it is very poor; they are slow to feed, slow to move, and yet slower in attaining maturity. The Alderney, though ill-shaped, is emphatically a better cow than either of the two last mentioned, always poor herself to enrich the milk pail, and though a great feeder yields very little milk; that milk, however, is of an extraordinary excellent quality, and gives more butter than can be obtained from any other cow. The above enumeration contains the description of all the breeds of cattle that we are familiar with, either personally or by reputation, that have been imported into the country for the purpose of crossing with our native stock. Of them all, your committee are of opinion, that the Improved Short Horns, for the rich and fertile valleys, and the North Devons, for the lighter but sweeter feed of the uplands, are the most profitable of all to cross with our native stock. They have been the longest in the country, and experience has proved their worth. The Galloways are probably next in importance, and the day may yet come when the hills of Franklin and Essex, and the whole Northern Frontier, for which they are admirably calculated, may be covered with them. It only remains to conclude this report, and in the words of a Lincolnshire farmer, we would say to those who are, or would be, engaged in the business of rearing stock of any description—"It should be an invariable rule to breed from small boned, straight backed, healthy, clean, kindly skinned, round bodied, and barrel shaped animals, with clean necks and throats, and little or no dew lap, carefully rejecting all those which may have heavy legs and roach backs, together with much appearance of offal."

W. A. S. NORTH,
Chairman of the Committee on Neat Stock.

Mr. H. S. Randall, of Cortland, from the committee on sheep, submitted the following report, which was accepted.

Report on Sheep.

The principal breeds of sheep in the United States are the "native," (so called;) the Spanish and Saxon Merinos, introduced from the countries whose names they bear; and the New-Leicester or Bakewell, the South Down, and some minor importations of Cotswold, Lincolnshire, &c. from England. Chancellor Livingston also speaks of two races as "indigenous" to this country, which we have not enumerated, as it is not known to the committee that they are now bred in any portion of the United States, viz. the Otter and Smith's Island sheep, breeds said to have been discovered on two islands on our Atlantic coast. An almost infinite variety of crosses have taken place between the Spanish, English, and "native" families. To so great an extent indeed has this been carried, that there are, comparatively speaking, few flocks in the United States, that preserve entire the distinctive characteristics of any one breed, or that can lay claim to unmixed purity of blood.

NATIVE SHEEP.

Although this name is popularly applied to the common coarse woolled sheep of the country, which existed here previously to the importation of the improved breeds, there is, properly speaking, no race of sheep "native" to North America. Mr. Livingston, in speaking of a race as "indigenous," only quoted the language of another,[*] and his informant was either mistaken as to the fact, or misapprehended the term. The only animal of the genus *Ovis*, originally inhabiting this country, is the Argali,[†] known to our enterprising travellers and traders who have penetrated to the Rocky Mountains, where the animal is found, as the Big Horn. Though the pelage of the argali approximates but little to the wool of the domestic sheep, they are, as is well known, considered by naturalists, to have belonged originally to the same species; and the changes which have taken place in the form, covering, and habits of the latter, are attributed to his domestication, and the care and skill of man during a long succession of years.

The common sheep of the United States were of foreign, and mostly of English origin. The writer of the volume on sheep in the "Farmer's Series," (Mr. Youatt,) speaks of them as "although somewhat differing in various districts, consisting chiefly of a coarse kind of Leicester, originally of British breed."[‡] Others have seen, or fancied they saw, in some of them a strong resemblance to the South Downs. Mr. Livingston was of this number.[§] But it is far more probable that they can claim a common descent from no one stock. Our ancestors emigrated from different sections of the British dominions, and some portion of them from other parts of Europe. They brought their implements of husbandry, and their domestic animals to fertilize the wilderness. Each, it would be natural to suppose, made choice of the favorite breed of his own immediate district, to transport to the New World, and the admixture of these various races formed the mongrel family now under consideration. Amid the perils of war and the incursions of beasts of prey, they were preserved with sedulous care. As early 1676, Mr. Edward Randolph, in a "Narrative to the Lords of the Privy Seal," speaks of New-England as "abounding with sheep."[‖]

The common sheep yielded a wool only suited to the coarest fabrics, averaging, in the hands of good farmers, from three to three and a half pounds of wool to the fleece. They were slow in arriving to maturity, compared with the improved English breeds, and yielded, when fully grown, from ten to twelve pounds of a middling quality of mutton to the quarter. They were usually long legged, light in the fore quarter, and narrow on the breast and back, although some rare instances might be found of flocks with the short legs, and some approximation to the general form of the improved breeds. The common sheep were excellent breeders, often rearing, almost entirely destitute of care, and without shelter, one hundred per cent of lambs, and in small flocks a still larger proportion. These, too, were usually dropped in March, or the earlier part of April. Restless in their disposition, their impatience of restraint almost equalled that of the untamed argali, from which they were descended, and in many sections of our country it was common to see from twenty to fifty of them roving with little regard to inclosures, over the possessions of their owner and his neighbors, leaving a large portion of their wool adhering to bushes and thorns, and the remainder placed nearly beyond the possibility of carding by the burs of the *Tory bur*, so common on new lands.

The old common stock of sheep, as a distinct family, have nearly disappeared, having been universally crossed, to a greater or less extent, with the foreign breeds of later introduction. The first and second cross with the Merino, resulted in a decided improvement, and produced a variety exceedingly valuable for the farmer, who rears wool only for domestic purposes. The fleeces are of uneven fineness, being hairy on the thighs, dewlap, &c.; but the general quality is much improved; the quantity is considerably augmented; the carcase is more compact and nearer the ground; and they have lost their unquiet and roving propensities. The cross with the Saxon, for reasons which we shall hereafter allude to, has not been generally so successful. With the Leicester and Downs, the improvement, so far as form, size and a propensity to take on fat are concerned, is manifest.

SPANISH MERINO.

The history of this celebrated race of sheep, so far as it is known, has so often been brought before the public, that it is deemed unnecessary here to recapitulate it. The first importation of them into the United States, took place in 1801. Four rams were shipped by Mr. Delessart, a banker of Paris, three of which perished on the passage.[¶] The fourth arrived in safety at Rosendale, a farm owned by that gentleman near Kingston, in this state. In 1802, two pair were sent from France by Mr. Livingston, the American minister, to his estate on the Hudson; and later the same year, Mr. Humphreys, our Spanish minister, shipped one hundred, on his departure from that country, for the United States. But they attracted little notice until our difficulties with England led to a cessation of commercial intercourse with that power in 1808 and 1809. The attention of the country being now directed towards manufacturing and wool growing, the Merino rose into importance. So great indeed was the interest excited, that from a thousand to fourteen hundred dollars a head, was paid for them. Other and numerous importations soon followed, and unfortunately some of the cargoes arrived in the worst condition, bringing with them those scourges of the ovine race, the scab and foot-rot. These evils and the increased supply, soon brought them down to less than a twentieth part of their former price; they could now be bought for twenty dollars a head. When, however, it was established by actual experiment, that their wool did not deteriorate as had been feared by many, in this country, and that they became readily acclimated, they again rose into favor. But the prostration of our manufactories, which soon after ensued, rendered the Merino comparatively of little value, and brought ruin to numbers who had purchased them at their previous high prices. The rise which has since taken place in the value of fine wool, as well as the causes which led to it, are too recent and well understood to require particular notice. With the rise of wool, the valuation of the sheep which bear it, has of course kept pace.

The Merino has been variously described. This arises from the fact, that it is but the general appellation of a species, comprising several varieties, presenting essential points and difference in size, form, quality of quantity of wool. The Escurial flocks stand first in point of fineness. Attached to the convent *El Escurial*, within a short distance of the capital, and being the private property of the kings of Spain, no pains or care have been spared upon these beautiful flocks. They are of a good size, and fine form, "combining excellence," as is remarked by an intelligent writer,* "scarcely admitting of improvement." It is supposed that most of the Escurial sheep which found their way into this country, are but indifferent specimens of this celebrated variety of the Merino. Their fleeces are somewhat lighter than those of the Paulars, Negrettis, &c. and altogether they bear a close resemblance to the *genuine* Saxons, of which they are the parent stock.

According to Mr. Lasteyrie,† the Negretti "are the largest and strongest of all the Spanish travelling sheep." The Gaudaloupe "have the most perfect form, and are likewise celebrated for the quantity and quality of their wool." The Paulars "bear much wool of a fine quality; but they have a more evident enlargement behind the ears, and a greater degree of throatiness."

As the last named was one of the principal varieties introduced into the United States, a more particular description of it may not be unacceptable. The sheep of the Paular Convent are large, with heavy, but compared with the Escurial or Saxon, coarse fleeces. The wool of the pure bloods contains a considerably quantity of jarr or hair, and it abounds in yolk to such a degree, that it catches and retains at its extremities much floating dust, the pollen of hay, &c. This gives it a peculiarly stiff and hard feeling externally. It, however, forms an excellent protection against storms and cold. The form of the Paular is generally good, but an unusually large dewlap, so plated and doubled, as to go by the popular appellation of "the ruffle," extends from the lower jaw to the brisket, presenting a great obstacle to the shearer, and an unseemly and ungraceful appendage in the eye of the refined breeder. On the sides of the neck, and not unfrequently the face, the skin also lies in loose wrinkles. The head is coarse, and in the male, usually surmounted by large horns. The skill of the American breeder has obviated some of those defects, and there are some few (very few) flocks claiming purity of blood, which have little or no jarr, and an almost entire absence of the throatiness, peculiar to this variety. It is to be apprehended, however, that in most such instances, they owe it to a cross with the Saxons.

There are some other varieties of the Merino, which we shall not pause to describe. Taken collectively, the Spanish rams, according to Chancellor Livingston, yield about eight and a half pounds of wool, and the ewes five, which loses half in washing—making four pounds and a quarter the average weight of fleece of the rams, and two and a half the average of the ewes.‡ Some varieties considerably exceed this estimate, and probably it would fall short if applied to the prime sheep of any variety. In the celebrated flock of French Merinos at Rambouillet, the average weight, exclusive of tag and belly wool, is six pounds to the fleece. It must be confessed, however, that both Mr. Livingston and Mr. Humphreys assert, that the Rambouillet sheep carry more wool than any of the Spanish flocks.§ Col. Humphreys, in a letter to the Agricultural Society of Massachusetts, even goes so far as to state, "that the improved stock of France yield *twice* as much wool as those of Spain." Some carefully selected small flocks in this country, which were "salved"‖ after the preceding shearing, have averaged, including the ordinary number of rams, four and a half pounds of wool to the head. The gummy thick wool of the Merino can be but imperfectly cleansed on the back of the animal, where it is the universal custom in the United States to wash it, and probably four pounds of *clean* wool would be as high as the maximum average in the choicest flocks. Few over go three and a half.

The Merino, though the native of a warm climate, becomes readily inured to the greatest extremes of cold, flourishing as far north as Sweden, without degenerating in fleece or form.¶ It is a patient, docile animal, bearing much confinement without injury to health, and we never have been enabled to discover in it that peculiar "voraciousness of appetite," ascribed to it by English writers.* Accurately conducted experiments have shown, that it consumes two pounds of hay per diem, in winter; the Leicester consumes from three and a half to four; and the common wooled American sheep would not probably fall short of three. The mutton of the Merino, in spite of the prejudice which exists on the subject, is short grained, and of good flavor when killed at a proper age, and weighs from eight to ten pounds to the quarter. It is remarkable for its longevity, retaining its teeth and continuing to breed, two or three years longer than the common sheep, or the improved English breeds; but it should be remarked in connexion with this fact, that it is corresponding slowly in arriving at maturity. It does not attain its full growth before three years old, and the ewes in the best managed flocks, are rarely permitted to breed before they reach that age. The Merino is not a good breeder, the bearing ewes giving little milk, and sometimes neglecting their lambs. Eighty per cent would probably be as high as the average number of lambs usually reared.

We have already adverted to the cross between the Merino and the native sheep. On the introduction of the Saxon family of the Merinos, they were universally engrafted on the parent stock—and the cross was continued until the Spanish blood was nearly bred out. When the admixture took place with pure blooded and prime Saxons, it resulted most favorably. A variety was produced superior to the Merino in form, carrying less wool, but this more than compensated by its increased fineness. The excessive throatiness of the Paulars disappeared, or was greatly diminished. But unfortunately these instances of judicious crossing were rare. Our country was flooded by eager speculators, with the grade sheep and refuse Merinos of Germany. Fineness of wool, during the period of this strange excitement, was made the only test of excellence—no matter how scanty its quantity—no matter how diminutive or miserable the carcase. Governed by such views, the holders of most of our Merino flocks purchased these pseudo Saxons, and the consequence was, as might have been foreseen, their flocks were ruined.

SAXON MERINO.

In the year 1765, Augustus Frederick, elector of Saxony, obtained permission from the Spanish court to import 200 Merinos, selected from the choicest flocks of Spain. They were chosen principally from the Escurial flock, and on their arrival in Saxony, were placed on a private estate belonging to the elector, under the care of Spanish shepherds. So much importance was attached to the experiment, as it was then considered, that a commission was appointed to superintend the affairs of the establishment; and it was made its duty to diffuse information in relation to the management of the new breed; to dispose of the surplus rams at prices which would place them within the reach of all holders of sheep; and finally, by explaining the superior value of the Merinos, to induce the Saxon farmers to cross them with their native breeds. Popular prejudice, however, was strong against them, and this was heightened by the ravages of the scab, which had been introduced with them from Spain, and which proved very destructive before it was finally eradicated. But when it became apparent that the Merino, so far from degenerating, had improved in Saxony, and that the Saxon wool exceeded the Spanish in fineness and value, the wise and patriotic efforts of the elector began to reap their merited success, and a revolution took place in popular sentiment. The call for rams became so great that the government resolved on a new importation, to enable them more effectually to meet it, and to improve still further the stock already obtained. For this purpose an individual, considered one of the best judges of sheep in Saxony, was dispatched to Spain in 1777, with orders to select three hundred. For some reason—probably because he experienced difficulty in obtaining a greater number presenting all the qualifications he sought, he returned with but one hundred and ten. They were from nearly all the different flocks of Spain, but principally the Escurial,—and were considered decidedly superior to the first importation. In addition to the establishment at Stolpen, already founded, others were now commenced at Rennersdorf, Lohmew, &c.; schools were established for the education of shepherds; publications were distributed by the commissioners to throw information on the subject before the people; and the crown tenants, it is said, were each required to purchase a certain number of the sheep. When we take into consideration the unwearied pains bestowed on this favorite object by the Saxon government—the fact, that the Saxon variety are descended only from the choicest sheep of Spain—and that a degree of care and attention are bestowed on their breeding in the former country entirely unknown in the latter—it is not a subject of suprise, that the emigrant Merino in Saxony excels the parent stock, in the quality of his fleece, and that roundness of form and fineness of bone, which indicate better feeding properties. The Spanish shepherd is little changed from what he was in the days of Cardinal Zimenes, or Pedro IV.—with much practical knowledge of his business, but never dreaming of improvement; and his knowledge strangely blended with prejudices as ancient as the pedigrees of his sheep—running back to a period when Spain was a Roman province. He is *not the owner of the sheep under his care*, but the ill-paid servant of a titled family; or a religious order, who in nine cases out of ten, are no more disposed, or more competent to carry out a system for the improvement of their flocks, than himself. And finally, the Spanish custom of pasturing their sheep during the entire season in large flocks, without inclosures* to render the necessary divisions practicable, entirely prevents that nice adaptation to each other of the male and female selected for breeding—that counterbalancing of the defects of one parent by the marked excellence of the other in the same points, which exhibits the skill of the modern breeder. In Saxony, and the other states of Germany, the case is far otherwise. The electoral flocks, the parent stem, are under the direction of commissioners appointed for their intelligence and knowledge of the subject; and the noted private flocks employ the first agricultural skill of the Saxon land-holders. The low price of labor, too, admits of a degree of attention and constant care over their flocks, unknown in other countries. The attention bestowed upon breeding, may be inferred from the fact, that in many of the largest flocks, every individual sheep is numbered and registered—its pedigree known, and its offspring recorded! The number and age of the sheep is expressed by an ingenious method of marking on the ear, invented by Mr. Thaer, which causes little mutilation, and which effectually distinguishes any number of sheep. "When lambs are weaned, (says Mr. Charles Howard, in a letter to the author of the volume on sheep in the "Farmer's Series,") each is placed upon a table that his wool and form may be minutely observed. The finest are selected for breeding, and receive a *first* mark. When they are one year old, and prior to shearing them, another close examination of those previously marked takes place: those in which no defect can be found receive a *second* mark, and the rest are condemned. A few months afterwards, a third and last scrutiny is made; the prime rams and ewes receive a *third* and final mark, but the slightest blemish is sufficient to cause the rejection of the animal."

Considerable attention has also been bestowed in Germany on the breeding of grade sheep—a cross between the Merino and the native sheep of the country. These native sheep were of two varieties, and they bore a strong resemblance to the old common stock of the United States,—those which were fed on the uplands being smaller and of finer fleece, and the lowland sheep carrying more flesh and coarser wool. The sheep holders, who were unable to purchase pure bloods, resorted to this cross. The wool of some of these flocks, after a few generations, has rivalled even the electoral in fineness; but it loses in quantity, as the native German carried much lighter fleeces than the Spanish sheep, The sheep themselves are much less perfect in form, the means of the common breeder not permitting, and indeed there being no prospect for an adequate return, should he bestow the same labor that the breeder of pure bloods does—sacrifice for the least defect, and, in short, incur the same expenses—when at best, his sheep will not sell for more than one-eighth or tenth of the price of pure bloods.

In 1834, the best Spanish wool sold in the English markets at 2*s.* 6*d.*, to 4*s.*; the Saxon at the same time commanded from 4*s.* 9*d.* to 5*s.* 3*d.* per pound.† In the United States, where less difference, and very unjustly, is usually made, the full blooded Saxon sells for about one-third more per pound than the Merino. The fleece in good flocks averages about two and a half pounds, and often, if grown sheep were only included, would rise as high as three. But this is far from the standard of many flocks in the United States, called, and doubtless believed by their owners, to be genuine Saxons. This brings us to a most painful part of our subject, and and which we would willingly pass over in silence, were not our obligations to the public paramount to any considerations for the feelings of individuals. In disclosing the frauds practised on the American public, we are compelled for the purpose of doing justice to the innocent and the guilty, and also for the information of those who have been the purchasers of the imported sheep, to go into a minuteness of detail, which would otherwise be uninteresting, and perhaps be deemed censurable.

The following statement was submitted to the committee by Mr. Grove:

"The first importation of Saxony sheep into the United States was made by Mr. ——— ———, a merchant of Boston, at the instance of Col. James Shepherd, of Northampton. They were but six or seven in number. In 1824, Messrs. G. and T. Searle, of Boston, imported seventy-seven Saxon sheep. They were selected and purchased by a Mr. Kretchman, a correspondent of the above firm, residing in Lepzig, and shipped at Bremen on board the American schooner Velocity. I was engaged to take charge of the sheep on the passage, and I also shipped six on my own account. I am sorry to say, that as many as one-third of the sheep purchased by Kretchman (who shared profit and loss in the undertaking,) were not pure blooded sheep. The cargo were sold at auction at Brookline, as 'pure blooded electoral Saxons,' and thus unfortunately in the very outset the pure and impure became irrevocably mixed. But I feel the greatest certainty that the Messrs. Searle intended to import none but the pure stock—the fault lay with Kretchman. In the fall of 1824, I entered into an arrangement with the Messrs. Searle to return to Saxony, and purchase, in connexion with Kretchman, from 160 to 200 electoral sheep. I was detained at sea seven weeks, which gave rise to the belief, that I was shipwrecked and lost. When I finally arrived, the sheep had been already bought by Kretchman. On being informed of what the purchase consisted, I protested against taking them to America, and insisted on a better selection—but to no purpose. A quarrel ensued between us, and Kretchman even went so far as to engage another to take charge of the sheep on their passage. My friends interposing, I was finally induced to take charge of them. The number shipped was 167, fifteen of which perished on the passage. They were sold at Brighton, some of them going as high as from $400 to $450. A portion of this importation consisted of grade sheep, which sold as high as the pure bloods, for the American purchaser *could not* know the difference. It may be readily imagined what an inducement the Brighton sale held out to speculation, both in this country and Saxony. The German newspapers teemed with advertisements of sheep for sale, headed '*Good for the American market;*' and these sheep in many instances were actually bought up for the American market at five, eight, or ten dollars a head, when the pure bloods could not be purchased at from less than $30 to $40. In 1826, Messrs. Scarle imported three cargoes, amounting in the aggregate to 513 sheep. They were of about the same character with their prior importations—in the main good, but mixed with some grade sheep. On the same year, a cargo of 221 arrived, on German account, Emil Bach, of Lepzig, supercargo. A *few* were good sheep, and of pure blood; but taken as a lot, they were miserable. The owners sunk about $3,000. Next came a cargo of 210, on German account; Wasmuss and Multer owners. The whole cost of these was about $1,125, in Germany. With the exception of a small number, procured to make a flourish on, in their advertisements of sale they were sheep having no pretentions to purity of blood. In 1827, the same individuals brought out another cargo. These were selected exclusively from grade flocks of low character. On the same year the Messrs. Searle made their last importation, consisting of 182 sheep. Of these I know little. My friends in Germany wrote me, that they were like their other importations, a mixture of pure and impure blooded sheep. It is due, however, to the Messrs. Searle to say, that as a whole, their importations were much better than any other made into Boston.

* Neither are there inclosures in Saxony; but the division is effected by the bucks being placed in pairs, and the ewes classified and marked. The ewes are from time to time driven in the yard around the pens, and when the teaser has selected one, it is placed in the pen of the buck for which it is marked.

† "Farmer's Series."

"I will now turn your attention to the importations made into other ports. In 1825, thirteen Saxons arrived in Portsmouth. They were miserable creatures. In 1826, 191 sheep arrived in New-York, per brig William, on German account. A portion of these were well descended and valuable animals; the rest were grade sheep. In June the same year, the brig Louisa brought out 173, also on German account. Not more than one-third of them had the least pretensions to purity of blood. Next we find 158, shipped at Bremen, on German account. Some were diseased before they left Bremen, and I am happy to state that twenty-two died before their arrival in New-York. All I intend to say of them is, that they were a most curious and motley mess of wretched animals. The next cargo imported, arrived in the brig Maria Elizabeth, under my own care. They were 165 in number, belonging to myself and F. Gebhard, of New-York. These sheep cost me $65 a head when landed in New-York. They sold at an average of $50 a head, thus sinking about $2,400! I need not say that they were exclusively of pure blood. A cargo of 81 arrived soon after, but I know nothing of their quality. The next importation consisted of 184, on German account per brig Warren. With a few exceptions they were pure blooded and good sheep. We next have an importation of 200, by the Bremen ship Louisa. They are commonly called the '*stop sale sheep.*' They were of the most miserable character, some of them being hardly half grade sheep. The ship Phoebe Ann brought 120 sheep, of which I know little, and 60 were landed at Philadelphia, with the character of which I am unacquainted. Having determined to settle in America, I returned to Saxony, and spent the winter of 1826–7 in visiting and examining many celebrated flocks. I selected 115 from the celebrated Machern, embarked on board the ship Albion, and landed in New-York June 27, 1827. In 1828, I received 80 more from the same flock, selected by a friend of mine, an excellent judge of sheep. I first drove them to Shaftsbury, adjoining the town of Hosic, where I now reside. On their arrival they stood me in $70 a head, and the lambs half that sum."

It should be remarked that the above statements were made by Mr. Grove with the greatest reluctance, and only at the earnest solicitation, or rather *requisition* of the committee, who conceived it their duty to place the whole circumstances before the public.

It will be inferred from the facts above stated, that there are few Saxon flocks in the United States, that have not been reduced to the quality of *grade* sheep, by the promiscuous admixture of the pure and impure, which were imported together, and *all* sold to our breeders as pure stock. This accounts in a satisfactory manner for the different estimation in which this breed of sheep are held in Germany and this country,—and for the degeneracy of the pseudo Saxon of the United States.

In its general habits and characteristics—its docility and patience under confinement—as well as its deficiency as a breeder, and its slowness in arriving at maturity, the Saxon bears a close resemblance to the Merino. It consumes about the same amount of food, and is equally remarkable for its longevity. Its mutton, however, is considered of better color, and rather superior in quality.

THE NEW LEICESTER OR BAKEWELL SHEEP.

The unimproved Leicester was a "large, heavy, coarse woolled breed" of sheep, inhabiting the midland counties of England. It is described also as having been "a slow feeder, and its flesh coarse grained, and with little flavor." The breeders of that period regarded only size, and weight of fleece. The celebrated Mr. Bakewell, of Dishley, was the first who adopted a system more in accordance with the true principles of breeding. He selected from the flocks about him those sheep "whose shape possessed the peculiarities which he considered would produce the largest proportion of valuable meat, and the smallest quantity of bone and offal," and having observed that animals of medium size possess a greater aptitude to take on flesh, and consume less than those which are larger, and that prime fattening qualities are rarely found in sheep carrying a great weight of wool, he gave the preference to those of smaller size, and was satisfied with lighter fleeces. To reach the wonderful results obtained by Mr. Bakewell, it was supposed that he resorted to a cross with some other varieties, but it seems now to be well established that he owed his success only to a judicious principle of selection, and a steady adherence to certain principles of breeding.

The improved Leicester is of large size, but somewhat smaller than the original stock, and in this respect falls considerably below the coarser varieties of Cotswold, Lincoln, &c. Where there is a sufficiency of feed, the New Leicester is unrivalled for its fattening properties, but it will not bear hard stocking, nor must it be compelled to travel far in search of its food. It is in fact properly and exclusively a lowland sheep. In its appropriate situation, on the luxuriant herbage of our highly cultivated lands, it possesses unrivalled earliness of maturity, and its mutton when not too fat is of a good quality, but is usually coarse and comparatively deficient in flavor, owing to that unnatural state of fatness which it so readily assumes, and which the breeder, to gain weight, so generally feeds for. The wethers having reached their second year are turned off in the succeeding February or March, and weigh at that age from thirty to thirty-five pounds to the quarter. The wool of the New Leicester is long, averaging, after the first shearing, about six inches, and the fleece weighs six pounds. It is of coarse quality, and little used in the manufacture of cloths, on account of its length, and that deficiency of felting properties, common in a greater or less extent, to all the English breeds. As a combing wool, however, it stands first, and is used in the manufacture of the finest bombazines.

The high bred Leicesters of Mr. Bakewell's stock became shy breeders, and poor nurses, but crosses subsequently adopted, have obviated these defects. In England, where mutton is generally eaten by the laboring classes, the meat of this variety is in very great demand, and the consequent return which a sheep possessing such fine feeding properties is enabled to make, renders it a general favorite with the breeder. Instances are recorded of the most extraordinary prices having been paid for these animals, and Mr. Bakewell's celebrated buck "Two-Pounder" was let for the enormous price of four hundred guineas for a single season! The New Leicester has spread into all parts of the British dominions, and been imported into the other countries of Europe and the United States. They were first introduced into our own country by the late Christopher Dunn, Esq. of Albany, about twenty-five years since. Subsequent importations have been made by Mr. Powel, of Philadelphia, and various other gentlemen.

We conclude this notice of the Leicester, with the following description of what should constitute a perfect animal of this breed, from the "Farmer's Series":

"The head should be hornless, long, small, tapering towards the muzzle, and projecting horizontally forward. The eyes prominent, but with a quiet expression. The ears thin, rather long, and directed backwards. The neck full and broad at its base, where it proceeds from the chest, but gradually tapering towards the head, and being particularly fine at the junction of the head and neck; the neck seeming to project straight from the chest, so that there is, with the slightest possible deviation, one continued horizontal line from the rump to the poll. The breast broad and full; the shoulders also broad and round, and no uneven or angular formation where the shoulders join either the neck or the back, particularly no rising of the withers, or hollow behind the situation of these bones. The arm fleshy through its whole extent, and even down to the knee. The bones of the leg small, standing wide apart, no looseness of skin about them, and comparatively bare of wool. The chest and barrel at once deep and round; the ribs forming a considerable arch from the spine, so as in some cases, and especially when the animal is in good condition, to make the apparent width of the chest even greater than the depth. The barrel ribbed well home, no irregularity of line on the back or the belly, but, on the sides, the carcase very gradually diminishing in width towards the rump. The quarters long and full, and, as with the fore legs, the muscles extending down to the hock; the thighs also wide and full. The legs of a moderate length, the pelt also moderately thin, but soft and elastic, and covered with a good quantity of white wool, not so long as in some breeds, but considerably finer."*

THE SOUTH DOWN.

This breed of sheep has existed for several centuries in England, on a range of chalky hills called the South Downs. They were as recently as 1776, small in size, and of a form not superior to the common woolled sheep of the United States. Since that period a course of judicious breeding, pursued by one man, (Mr. Ellman, of Gluyde,) has mainly contributed to raise this variety to its present high degree of perfection, and that too, without the admixture of the slightest degree of foreign blood. In our remarks on this breed of sheep, it will be understood that we speak of the pure *improved family*, as the original stock, presenting with trifling modifications, the same characteristics which they exhibited sixty years since, are yet to be found in England—and as the middle space is occupied by a variety of grades, rising or falling in value, as they approximate to, or recede from, the pure blood.

The South Down is an upland sheep, of medium size, and its wool, which in point of length belongs to the middle class, is estimated to rank with half grade merino. The average weight of fleece in the hill fed sheep is three pounds, and in the lowland, four pounds. But the Down is cultivated more particularly for its mutton, which for quality takes precedence of all other in the English markets. Its early maturity, and extreme aptitude to lay on flesh, render it peculiarly valuable for this purpose. The Down is turned off at two* years old, and its weight at that age is from 80 to 100 pounds. High fed wethers in England, have reached from thirty-two to even forty pounds a quarter! Notwithstanding its great weight, the Down has, in the language of Mr. Youatt, a patience of occasional short keep, and an endurance of hard stocking, equal to any other sheep. This gives it a decided advantage over the bulkier Leicester, Lincolns, &c. as a mutton sheep in hilly districts, and those producing short and scanty herbage. It is hardy and healthy, though in common with the other English varieties much subject to the catarrh or "snuffles," and no sheep better withstands our American winters. The Ewes are prolific breeders and good nurses. The Down is quiet and docile in its habits, and though an industrious feeder, exhibiting little disposition to rove.

A sheep possessing such qualities, must of course be exceedingly valuable in upland districts in the vicinity of markets. Accordingly, they have been introduced into every part of the British dominions, and imported into various other countries. The Emperor of Russia, paid Mr. Ellman, three hundred guineas for two rams, and in 1800 "a ram belonging to the Duke of Bedford, was let for one season at eighty guineas, two others at forty guineas each, and four more at twenty-eight guineas each."† These valuable sheep were introduced into the United States a few years since by Col. J. H. Powell, of Philadelphia, and a small number was imported by one of the members of this committee in 1834. The last were from the flock of Mr. Ellman, at a cost of $60 a head. Several other importations have since taken place.

The following is the description of the perfect South Down by Mr. Ellman, the founder of the improved breed:—

"The head small and hornless; the face speckled or gray and neither too long or too short. The lips thin, and the space between the nose and the eyes narrow. The under jaw, or chap, fine and thin; the ears tolerably wide and well covered with wool, and the forehead also, and the whole space between the ears well protected by it, as a defence against the fly.

"The eye full and bright, but not prominent. The orbits of the eye, the eye cap, or bone, not too projecting, that it may not form a fatal obstacle in lambing.

"The neck of a medium length, thin towards the head, but enlarging towards the shoulders, where it should be broad and high, and straight in its whole course above and below. The breast should be wide, deep and projecting forwards between the fore legs, indicating a good constitution and a disposition to thrive. Corresponding with this, the shoulders should be on a level with the back, and not too wide above, they should bow outward from the top to the breast, indicating a springing rib beneath, and leaving room for it.

"The ribs coming out horizontally from the spine, and extending far backward, and the last rib projecting more than others, the back flat from the shoulders to the setting on of the tail; the loin broad and flat; the rump long and broad, and the tail set on high, and nearly on a level with the spine. The hips wide; the space between them and the last rib on either side as narrow as possible, and the ribs generally presenting a circular form like a barrel.

"The belly as straight as the back.

"The legs neither too long nor too short. The fore legs straight from the breast to the foot; not bending inward at the knee, and standing far apart both before and behind; the hock having a direction rather outward, and the twist, or the meeting of the thighs behind, being particularly full, the bones fine, yet having no appearance of meekness, and of a speckled or dark color.

"The belly well defended with wool, and the wool coming down before and behind to the knee, and to the hock; the wool short, close, curled and fine, and free from spiry projecting fibres."

Mr. Allen, from the committee on horses asked further time to report. Granted, and directed to report at the next annual meeting of the society.

Mr. Buel, from the committee on swine, read the following report, which was accepted.

---

* Sheep Husbandry, p. 110.

* Among breeders the sheep is termed a two year old or a two shear sheep until three years old. In this case the sheep is between two and a half and three years old.

† "Farmer's Series."

Report on Swine.

The committee appointed at the last annual meeting of the society, to inquire into the progress made in the improvement of swine, submit the following report :

All the breeds of hogs known among us are supposed to have sprung from the Wild Boar *(Sus aper)* of the old continent. The varieties are numerous, and are annually increasing by new crosses. They differ in size, color, propensities to fatten, and in the quality of their pork—the smaller breeds affording the more fine and delicate meat, and the larger ones giving the most meat. The names of breeds indicate their origin, or some peculiar property.

There are good points in the hog, which are similiar to what they are in other domestic animals ; they indicate a disposition to fatten readily, and constitute beauty, because they are the criteria of utility. The chest of the hog should be deep and broad; the ribs largely arched; the neck short, and the head and limbs small; the bristles should be short, approaching to hair, and the skin soft and elastic.

The breeds in highest repute in Great Britain, are stated by Low to be the Chinese, Berkshire and Hampshire; the first admired for the whiteness and delicacy of its flesh; the second for its hardiness, quick fattening properties, and the excellence of its flesh for pork or bacon; the latter for the great weight which it is made to attain.

The Chinese hog is distinguished by having the upper part of the body almost bare; its belly hanging nearly to the ground; its legs very short, and its tail still more proportionably short. The color is commonly a dark grey, but often of other shades. This breed has been advantageously crossed with several other varieties.

The Berkshire hog, is generally of a tawney, white, or reddish color, spotted with black, according to Loudon, though with us the black color seems to preponderate; thick, close and well made in the body; legs short; small in the bone, and has a disposition to fatten quickly.

The Hampshire hogs are large, long in the body and neck, but not so compact as the Berkshire; generally white or spotted, and well disposed to fatten, coming up to a great weight. Lawrence adds that they are generally dark spotted, and sometimes black.

This reference is made to foreign breeds, because most of our improved varieties consist of one or the other of them, or of their crosses. Little attention has yet been paid, among us, to rearing new breeds; yet, from the spirit of improvement which is diffusing itself over our country, we may expect soon to see such improvements successfully gone into. The difference, in the return of meat for the quantity of food consumed, is very great between different varieties—there being some that can scarcely be made fat, even at an advanced age, with abundance of food.—There is no domestic animal which can be more readily improved in its form, from the facility with which it receives the character of its parents, and none more capable of a rapid increase.

There is a breed which abounds in our country, denominated the *Tonewanta,* from the writer having seen some pure unmixed individuals of the breed in that quarter, though they yet abound in other parts of the state. They are a long-legged, long-necked, long-snouted, long-tailed, long-bristled, razor-backed species, of a roaming mischievous disposition. A friend had kindly made a drawing of one of these animals, which we designed to have exhibited here in *terrorem,* and as a caution against their further propagation among us. But we have mislaid the pencil sketch.

So little attention has been paid to the improvement of the hog, until within a few years, among us, that it is difficult to particularize or describe our best breeds. The grass breed was long in deservedly high repute; but as little care was had to preserve its purity and excellence, it has mingled and been almost lost in our innumerable sub-varieties. The Chinese has had its day with some, the Mackay is still a favorite at the east; and there are other varieties in equal repute in other districts of our country. The Berkshire, however, seems now to be ascendant generally. These have been in most demand during the last two years, have commanded high prices, and have been sent, in considerable numbers, from this city, to almost every part of the union. The stock from which the Berkshire breed has been propogated, was selected in England, and imported some five years ago, by Mr. Siday Hawes, who at that time emigrated and settled in this neighborhood. The stock was subsequently transferred to C. N. Bement, who became Mr. Hawes successor upon what is denominated the *Three Hills Farm.*

The committee are happy to state, that an increased interest is now given to the fattening of pork as constituting a profitable staple of our husbandry; that the advantages of improved breeds, in beauty of form, facility of fattening, and profit of feeding, are becoming daily more apparent; that our general stock has been greatly improved —and that the improvement promises to progress. The new facilities of making pork upon the farm, by the aid of the apple orchard, and the increased culture of roots; and from the excellent practice, now becoming general, of grinding or cooking the provender and roots upon which our hogs are fed, added to the uniform fair demand for this meat in the market—all these considerations combine to give an importance to this branch of rural economy, which is worthy the special notice of the farmer.

Respectfully submitted.
J. BUEL, *Chairman.*

On Motion of Mr. Randall of Cortland,

Resolved, That Messrs Buel and Randall be a committee to prepare the proceedings of the society for publication and that said committee furnish copies to the editors of The Cultivator and Genesee Farmer for publication.

On motion of Mr. Buel,

Resolved, That this society adjourn to meet at the City-Hall on the first Tuesday in Feb. 1839.

JOHN P. BEEKMAN, *Prest.*
H. S. RANDALL, *Sec.*

N. Y. St. Agricultural Convention.

The Convention assembled agreeably to public notice, in the Mayor's Room, in the City-Hall of the city of Albany, on the 1st day of February, 1838. W. A. S. North of Schenectady, was called temporarily to the chair, and Henry S. Randall, of Cortland, was chosen secretary, p. t.

On motion of J. Buel, it was

Resolved, That Messrs. J. P. Beekman, of Columbia, L. F. Allen, of Erie, J. Buel, of Albany, H. Baldwin, of Onondaga, and J. B. Duane, of Schenectady, be a committee to report suitable names for officers of the convention.

On motion of J. P. Beekman, it was

Resolved, That Messrs. H. Baldwin, J. Buel, A. Van Bergen, of Greene, F. Rotch, of Otsego, and H. S. Randall, be a committee to report subjects that ought to be brought before the convention, and the order of proceedings thereon.

The convention then adjourned to meet at the Assembly Chamber at 3 o'clock P. M.

Assembly Chamber, Feb. 1. 3. P. M.

The convention met pursuant to adjournment.

Mr. Beekman, from the committee to nominate officers for the convention, reported the following, which was accepted by the convention,

JAMES R. LAWRENCE, of Onondaga, *President.*

AVERY SKINNER, of Otsego,
DANIEL WARDWELL, of Jefferson,
D. S. DICKERSON, of Broome,
A. VAN BERGEN, of Greene,
F. ROTCH, of Otsego,
G. W. PATTERSON, of Livingston,
E. HALL, of Oneida,
R. SWARTWOUT, of Tompkins,
C. DUBOIS, of Dutchess,
C. BERGEN, of Kings,
J. J. VIELE, of Rensselaer,
J. S. SPENCER, of Madison,
V. Presidents.

HENRY S. RANDALL, of Cortland,
R. L. ALLEN, of Erie,
JOHN FRY, of Montgomery,
SAMUEL HOAG, of Rensselaer,
Secretaries.

The following delegates appeared and took seats in the convention.

Albany—Jesse Buel, John Townsend, William Thorburn, John Willard, James D. Wasson, J. K. Paige, C. N. Bement, Samuel Cheever, Charles Smith.

Allegany—Seth H. Pratt.

Cattaraugus—Nelson Green, S. A. Goodwin.

Chautauque—Geo. A. French, Abner Lewis.

Chenango—Henry Balcom, D. Hubbbard, jr, Justus Pearce.

Clinton—Percival Morse.

Columbia—S. Van Buren, P. I. Storrs, John VanSlyck, Wm. Bain, J. P. Beekman, A. B. Ludlow, Joab Center, Wm. H. Wilson, Adam L. Shaver, I. Crocker.

Cortland—D. Matthews, I. Osgood, E. W. Edgecomb H. S. Randall, N. Gillet.

Dutchess—Freeborn Garretson, Cornelius Dubois.

Erie—Richard L. Allen, Cyrenus Wilbur, A. Warner, L. F. Allen.

Essex—Gideon Hammond.

Franklin—Luther Bradish.

Genesee—A. H. Green, John Head.

Greene—Seth Hawley, J. P. Hawley, A. T. Van Slyck, A. Van Bergen, Martin G. Van Bergen.

Herkimer—Abijah Mann, jr, Volney Owen, Aaron Petrie.

Jefferson—D. Wardwell, Chancey Baker.

Kings—Cornelius Bergen.

Livingston—N. Scott.

Madison—Mr. Lord, Mr. Bostwick, Mr. Spencer. Derick Sibley, W. C. Bloss.

Montgomery-John Fry, G. Gortner, jr, A. V. Putnam, E. W. Prindle, J. L. Bevins, A. A. Nestall, A. W. Sebor.

New-York—John Harris, H. W. Childs.

Oneida—W. C, Noyes, F. C. White, R. Fuller, J. H. Ostrom, E. Mart, E. Elmer, H. Hearsey.

Onondaga—S. L. Edwards, E. Lynds, H. Baldwin, G. Lawrence, A. Smith, P. Gould, Victory Birdseye, James R. Lawrence, Wm. Gibbs, Henry Lawrence.

Ontario—Jonathan Buell.

Orange—Hudson McFarlan.

Oswego—Saml. Freeman, Jno. M. Richardson, A. Rice, L. Babcock, T. S. Morgan, Jos. E. Bloomfield.

Otsego—L. Beardsley, Saml. Betts, jr, Jacob K. Snell, John Drake, Francis Rotch.

Orleans—Horatio Reid.

Putnam—Saxton Smith.

Queens—John A. King.

Rensselaer—H. D. Grove, L. C, Ball, Jas. Wallace, Alex. Walsh, Hezekiah Hull, Wm. A. McCullock, A. D. Spoor, Jacob Ten Eyck, Cornelius Lansing, jr, John J. Viele, Joseph Hastings, Wm. S. Clapp.

Saratoga—H. C. Foster.

St. Lawrence—M. G. Peck.

Schenectady—Jno. B. Duane, John Ferguson, W. A. North, J. H. Strang, Wm. B. Walton, J. A. Tower, S. G. Tower.

Sullivan-J. H. Bowers, Jno. Maynard, Nathan Wakeman.

Tioga—John Coryell.

Tompkins—E. Curtiss.

Washington—Martin Lee, L. Gibbs, E. D. Culver, E. Smith, J. W. Richards, Jas. Martin, Jno. Crary, L. B. Armstrong, Jno. McDonald, Thos. Whiteside, Jno. Rost, Nathan Wilson.

Wayne—A. L. Beaumont.

Yates—Miles Benham.

Mr. Buel, from the committee on the subject of the Grain worm, presented the following report.

The committee appointed at the last Agricultural Convention, "to collect facts in regard to the history and habits of the Grain worm, to its ravages upon our farm crops, and to the means, if any are known, of preventing its depredations," offer the following report.—

The habits of the Grain worm, believed to be the *Tipuli,* or *Cecidomia tritici* of entomologists, are yet but imperfectly known among us. We find in Kirby & Spence's Entomology, one of our best authorities upon insects, but an incidental notice of one insect that can be considered identical with this. The following is the passage:

"When the wheat blossoms, another marauder, to which Mr. Marsham first called the attention of the public, takes its turn to make an attack upon it, under the form of an orange colored gnat, which, introducing its long retractile ovipositor into the centre of the corolla, there deposites its eggs. These being hatched, the larvae, perhaps by eating the pollen, prevent the impregnation of the grain, and so in some seasons destroy the twentieth part of the crop." Vol. 1. p. 172-3.

Professor Low, in his Elements of Practical Agriculture, p. 236, has the following notice of the insect:

"The *Cecidomia Tritici,* is a fly with an orange colored body and white wings. About the month of June the female ascends the ears of wheat, and deposites her eggs in these, by means of a fine trunk, and in a few days she perishes. The progeny being hatched in the ear, feed upon the grain. They are very small, from two to fourteen being sometimes found in one grain, and are distinguished by being of a bright orange color. They do not extend beyond the grain in which they had been born; but several grains being thus consumed in each ear, the damage done is often considerable. The larvae, after a period, fall down to the earth, in which they burrow, and remain there till the following summer, when they ascend from the earth in the form of the beautiful fly which has been mentioned."

Practical farmers have been able to add to our knowledge in regard to the habits of this insect. When wheat sown at the ordinary season, is developing its head, a species of fly is seen in great numbers, principally about sunset, attaching themselves to the ears, where they deposite their eggs, which in about ten days after become maggots, or catapillars. These destroy the young pickle, by sucking up the milky juice which swells the grain, and thus depriving it in part, and in some cases perhaps of the whole of the moisture, cause it to shrink up, and become an abortion. In about three weeks after, when it has exhausted this substance the insect falls from the head, either upon the leaves or ground, and if upon the latter it shelters itself about half an inch below the surface, where it remains dormant, until the mean temperature of about 50 degrees in the spring, brings forth the perfect fly, about the time the wheat comes in the ear. Such seems to be the most accurate account of the habits of the insect which we have been able to obtain.

Mr. Henry Green, of Washington County, has cited two instances, one in his own practice, of the insects emerging from the chrysalis to the perfect fly in autumn, in immense numbers; but this was caused as he well supposes, by the heating of the grain in the barn, the chrysalis being carried to the barn with the straw and chaff, in consequence of the grain having been housed in a greenish damp state.

We find no notice of the ravages of this insect till the year 1820. During the subsequent ten years it caused immense damage in some districts of Scotland, sometimes destroying, as it has done here, a fourth, a third, or half the crop, and in many instances the grain was so badly injured as not to be worth harvesting. In 1829, in the district denominated the carse of Gowry, the damage which the grain worm did to the wheat crop, was estimated at nearly two hundred thousand dollars. It has been known in the northern parts of this state and Vermont for the last ten years. It seems to have been first noticed upon the borders of Vermont and Lower Canada, and thence to have extended north and south. Its progress has been from 40 to 60 miles a year, east, west and south. It has now extended through Maine on the east, to Dutchess on the south, and to the Valley of the Genesee, partially, on the west. It will probably continue to enlarge the sphere of its operations, until it embraces the entire wheat growing districts of the union.

The depredations of the grain worm have tended greatly to lessen the culture of wheat where it has shown itself, and to reduce the product of that which has been sown, The product, from these causes, has been reduced four fifths in some districts. A like diminution in the wheat districts of the west, which may be feared, when like causes operate there, will be truly calamitous, not only to the farmer, but to the state at large. We cannot shut our eyes to what has happened, nor should we disregard the admonition which it conveys, to provide against the evil in due time.

No certain preventive is known for the evil. It would seem, that the most probable means of averting it, is to sow winter wheat early, say the beginning of September, and spring wheat late, perhaps after the tenth of May, in this latitude. The grain of the first may become indurated and hard, before the worm is hatched, and will of course escape injury. The latter will come into head after the fly has disappeared, and that too will escape. We are not prepared to say, however, that these rules will prove infallible. It is stated in the Maine Farmer, by Mr. Norcross, that he sowed on the last Friday of April, and on the 5th May. The fly appeared in great abundance on the first sowing, but as most of the grain was then past the blossom the injury was only in the late heads, and the damage to the crop did not exceed a twelfth. That sowed on the 5th of May was reduced in produce one half by the worm. We sowed on the 5th May, and although we saw flies upon the grain for five or six evenings after it had come into head, the injury did not probably exceed one fourth of the crop. We examined several fields of wheat sown from the 10th to the 22d May, and was not able to discover in them the least indication of the worm. These facts would seem to indicate, that if wheat is sown very early in autumn, or to late in the spring, the crop may escape the grain worm, or be but partially injured by it. Yet we want further experience—more facts—before we can lay down any certain rules.

The observations of practical men have led to this further conclusion, that good culture tends to lessen the evils of the grain worm, inasmuch as it imparts health and vigor to the crop, and accelerates the early developement of the blossom in the winter varieties before the fly appears. We have had cases cited to us, where parts of fields, being low, wet, badly cultivated, or affected with rust, were almost wholy destroyed by the worm; while other parts of the same field, upon dry, well cultivated ground, and the straw unaffected by rust, were but partially, or not at all attacked—the kernel having become indurated, before the worm was in a condition to prey upon it.

It is proper we should here remark, that a complete preventative has been announced as having been discovered by S. W. Jewett, of Weybridge, Vt. We know Mr. Jewett to be highly respectable farmer; he has confided to us his secret; and we have no doubt it has proved efficacious with him But the difficulty is in applying the preventive on a large scale, and the still greater difficulty of applying it in some districts at all. Mr. Jewett asks but a moderate compensation for his secret.

Kirby and Spence remark, in their work which we have quoted, with no little force, that among the various instruments which the Almighty ordains for the punishment of offending nations, and the more to manifest and glorify his power—

"He employs means, at first sight apparently the most insignificant and inadequate to effect their ruin: the numerous tribes of *insects* are his armies, marshalled by him, and by his irresistable command impelled to the work of destruction; where he directs them, they lay waste the earth, and famine and pestilence often follow in their train. The generality of mankind, say they, overlook or disregard these powerful, because minute, dispensers of judgement; seldom considering in how many ways their welfare is affected by them; but the fact is certain, that should it please God to give them a general commission against us, and should he excite them to attack, at the same time, our bodies, our clothing, our houses, our cattle, and the produce of our fields and gardens, we should be reduced, in every possible respect, to a state of extreme wretchedness; the prey of the most filthy and disgusting diseases, divested of a covering, unsheltered except by caves and dungeons, from the inclemency of the seasons, exposed to all the extremities of want and famine, and in the end, as Sir Joseph Banks, speaking on this subject, has well observed, driven with all the larger animals from the face of the earth."

The afflicting dispensations of Providence, are not only designed to punish men for their transgressions, but to awaken in them a constant and active vigilance, essential to their health and happiness; and under this view, the injuries which we now suffer from the insect enemy which is the subject of this report, may lead to renewed exertions in the performance of the great duties of life.

The committee will close their report with recommending, that the legislature of our state be requested by this convention, to offer a liberal bounty for the discovery of a preventive of the ravages of the grain worm.

Mr. Buel also read the following most able and interesting paper,—

On the Necessity and Means of Improving our Husbandry.

We cannot be too often reminded of the contrast which exists between good and bad husbandry,—nor too often admonished to search into the causes of this difference, and to apply the needful remedies. The difference does not consist alone in a single crop, or a single season: The soil in one case is becoming more and more exhausted of fertility, and losing its intrinsic value, while in the other its relative worth is on the increase, and the difference in product is consequently annually increasing.

We will illustrate our proposition by a comparison between American and Scotch husbandry, now and sixty years ago. Sixty years ago, the agriculture of Scotland, was in a wretchedly low and unproductive condition; while the products of our yet unexhausted soil were abundant. But sixty years ago the spirit of improvement fell upon Scotland, her agricultural society was instituted, and commenced its useful labors, and was soon after greatly aided by the organization of a national board of agriculture; agricultural surveys were made and published of every county—the best practices of every district thus became known to the whole nation—men of fortune and science turned their attention to the encouragement and improvement of this parent art;—and the consequence has been, that a wonderful and salutary change has come over that land, fraught with abundance and with blessings. The value of land has in consequence been enhanced three and four fold, and its products have been increased in a proportionate ratio. "In fertile districts," says Sir John Sinclair, "and in propitious seasons, the farmer may confidently expect to reap, from 32 to 40 bushels of wheat; from 42 to 50 bushels of barley; from 52 to 64 bushels of oats, and from 28 to 32 bushels of beans, per statute acre. As to green crops, 30 tons of turnips, three tons of clover, and from 8 to 10 tons of potatoes, per statute acre, may confidently be relied on. In favorable seasons the crops are still more abundant."

Now, what has been our progress during the last sixty years? Has it not been retrograde in agriculture? We have, to be sure, obtained abundant crops from our rich virgin soils, and when these have become exhausted, under bad management, we have occupied and exhausted others in their turn. But what is the condition *now* of the lands that were cultivated by our fathers half a century ago? Do *they* produce the average crops which are given above as the products of Scotch husbandry?—under all our favorable circumstances of climate and of civil liberty. Are our crops *half* as large? Nay, are they more than a *third* as large? Do we get from our old districts, an average of more than 10 to 13 bushels of wheat, of 14 to 17 of barley, or of 17 to 21 bushels of oats per acre? At the close of the last, and in the beginning of the present century, the surplus products of northern agriculture were *exported*, to an immense amount. Now we *import* the agricultural products of Europe, to avert the evils of famine! The cause of this remarkable difference, in the surplus products of the soil, may be partially owing to unpropitious seasons, but is mainly to be sought for in the neglect of our agriculture—both by the people and the governments. In Europe, the governments, and influential individuals, have bestowed spirited attention upon the improvement of agriculture, as constituting the basis of national prosperity and independence. While with us, improvement in husbandry has been considered a minor concern,—it at least has not received the consideration of the statesman or the political economist. Party politics, and local or personal schemes of aggrandizement, have so much engrossed the attention of the men who *ought* to lead in these matters, and who *do* lead in every other public improvement, that the humble claims of agriculture have failed to attract their notice, or engage their attention, although it constitutes the base which supports the whole superstructure of civilized society.—If we would preserve the superstructure, with its embellishments, we must take care to make strong and permanent this foundation. Our farmers, too, seem generally indifferent, or spiritless, in regard to the general improvement of our agriculture, either because they mistake their duty and true interest, or that, under the influence of a strange fatuity, they fear they shall sink as others rise.

We should consider our soil as we do our free institutions—*a patrimonial trust--to be handed down*, UNIMPAIRED, *to posterity;* to be *used*, but not *abused*.—Both are more easily impaired than they are restored—both belong, in their pristine vigor and purity, as much to our children, as they do to us. In some of the once populous and fertile districts of the old continent, the fertility of the soil has been recklessly wasted by men, whose descendants have, consequently, become poor and wretched, and their country almost virtually a desert. In other portions, where the fertility of the soil has been sedulously preserved for ages, or centuries, the population has continued prosperous, wealthy and happy.

It is undeniably true, that our general system of farming is bad; that in most parts of our country the natural fertility of the soil has been gradually diminishing, and its products becoming less; that the evil is increasing; and, that without a radical reform, we shall, in the north, not only cease to have surplus products to pay for the foreign commodities which long habit has rendered necessary to our convenience, but lack a supply of bread stuffs for our own population. To what degrading dependence will this course of things in a few years reduce us—unless prompt and efficient means are adopted to check our down-hill course in the products of agricultural labor!—With the finest country in the world, a population almost entirely agricultural,—exempt from the enormous burthens, as tithes, rents and poor rates, which press like an incubus upon the agricultural labor of Europe,—and dependant on foreign supplies for the means of subsistence!! The idea is humiliating—is alarming—to all who look to the ultimate prosperity and happiness of our country. Our maritime commerce depends upon contingencies which we can neither foresee nor control. Venice and Genoa, and Portugal and Spain, have each in turn, had their "days of commercial prosperity"—they successively rose to opulence—to power—and successively sunk, the victims of corruption, into effeminacy, vice, and despotism. Manufactures too, as we have had abundant cause to know, are but a precarious dependence for national greatness. Commerce and manufactures are the shaft and capital of the social column, of which agriculture constitutes the base; and without this base, they can no more withstand the shocks and revolutions of time, than could the short lived glory of the nations we have named. Great Britain now wields the trident, and the world is made tributary to her workshops. But great as she is in commerce, and in manufactures, these are considered secondary and auxiliary to her agricultural greatness. Land is the basis of her national wealth,—it is the surplus marketable produce of her soil, says Sir John Sinclair, that is the source of all her political power, and of the personal enjoyment of her citizens; and there is no source of domestic industry, or of foreign commerce, he adds, that can in any respect be put in competition with the improved cultivation of her soil. The agriculture of Great Britain employs but two-thirds of her population; and yet the surplus products of her soil, suffice to feed and support the other third, and to assist in supplying our deficiencies. Our population is at least five-sixths agricultural; yet during the two last years we have had to import about ten millions worth of bread stuffs to supply our deficiency in this first element of life; and even in the most favorable seasons, the exports of the surplus products of our northern soil, have been merely nominal.

We will state one fact, derived from official documents, which will demonstrate beyond the power of refutation, our down hill course in this great branch of national industry. It is this: the average increase of bread stuffs, passing from our canals to tide waters, from the great grain district of the west—from the Flanders of America,—has amounted to three and three quarters per cent; while our population has increased in the ratio of six per cent per annum! If such has been the deficiency, in our grain growing, new and fertile districts, to meet the wants of our increasing population—how much greater must that deficiency have been in the exhausted soils of old settled districts? Many portions of our country, which once exported grain, have, by bad husbandry, become dependent upon the comparatively new settlements, or upon foreign supplies, for this indispensable necessary of life. This remark will apply to almost our entire Atlantic border.—Will any mathematician tell us, how long it will require, according to the disproportionate ratio of increase, between our population and our means of subsistence, to reduce us to a state of absolute dependance? or, to a state of national want and famine.

It is apparent, from the examples of improvement which are witnessed in many districts of our country, that we CAN improve the general condition of our agriculture, if we will adopt a wise and energetic policy. Nay, we have a demonstration of the practicability of doing it, in the now palpable benefits of the law to improve our agriculture, passed in 1819. That law involved an expenditure of 40 or 50,000 dollars, and expired in 1824. It was found fault with by many from political motives, and by more from a spirit of envy, in those who either had not the enterprise or the talent to compete successfully for the rewards which it gave to industry and skill. And besides, the law, in some instances, was badly, we may almost say corruptly, executed Yet under all the disadvantages of want of organization, of inexperience and abuse, has not that expenditure been like manure spread upon our soil? Did not that law excite a laudable emulation among the whole farming community, and bring into action more skill, more industry, and more improvement? Has it not been instrumental in greatly improving our farm stock, our farm implements, and modes of culture? Has it failed to increase the farm products of any one county, of a respectable population, to the amount of the total expenditure? Or, has it failed to return into the treasury, every year, the gross amount of that expenditure, in the form of canal tolls upon the increased productions of the soil? We do not put these questions because *we* have any doubts in the matter, but to bring the subject home to the calm and deliberate consideration of those reflecting men, whose duty and interest is to scan, to judge, and to act wisely, upon a question of momentous importance to our country. If these men think with us, that the law of 1819 has amply remunerated the state, for its expenditure, on the increased tolls on our canals, and that it has added millions to the value of our annual agricultural products, they will not hesitate to renew that policy which has been productive of so much public good. The improvements of the last eighteen years might have been respectable without the aid of that law; but it was *that* which gave a new impetus to improvement. The fairs and exhibitions which it produced, taught our farmers, that there was yet much to learn in their business;—that they could improve, in their farm stock, in their farm implements, in their seeds, and in their modes of culture—and many of them resolutely determined to profit, and did profit, by the lessons of instruction which they then imbibed. And when the spirit of improvement has begun, it is like civil revolution,—it seldom retrogrades. One improvement leads to others, as naturally as the active mind, having attained to one branch of knowledge, soars to other and higher branches. Our southern brethren say, we are in advance of them greatly in agricultural improvement. If this is so, we owe this distinction in rural improvement to the law that was passed, upon Gov. Clinton's recommendation, in 1819.

It requires no science, and very little art, to wear out and exhaust the most fertile soil. The process is simple: take from it all you can, by close cropping, for a few continuous years, and return to it nothing in the form of manure, and the work is done, or far advanced. In this business we have shewn ourselves to be no mean adepts. But it does require science, and art, and perseverance and capital, to restore fertility to a soil which has become exhausted. This we have not yet sufficiently learned; but it should be our next lesson; and the sooner we begin, the sooner shall we profit by it.

Agricultural improvement is slowly developed, at least to superficial observers. It requires years to renovate the fertility of an exhausted soil—to improve the stock of a farm; or to realize the benefits which result from draining, from alternating crops, and from root culture. We are much in the habit of calculating upon *immediate* gains, without looking to remote and ultimate benefits. We saw not the change, when the law of 1819 was in force, because its benefits were but partially developed. But we now hear the remark from hundreds, that the appropriation of 1819, was one of the most beneficial to the state that has ever been made by the legislature. The popular vote of the state would never have sanctioned the construction of the Erie and Champlain canals; and yet the wisdom of the measure is now sanctioned by an enlightened world. Although the construction of these canals, may have operated prejudicially to some individuals and districts, yet the benefits which have resulted to the whole state have amply compensated for any personal inconvenience or injury they may have caused. So with the law to encourage agriculture; many did not foresee its benefits, who now acknowledge that they are palpable and important. We must judge of public measures by their fruits; and before we are competent to do this, the seed must germinate, the plant grow and blossom, and the fruit mature. This is particularly the case in all measures to improve agriculture. It is the province of wisdom to look ahead—to sow the useful seed, and to wait the coming harvest for the recompense. We must sow in the spring—and cultivate well in the summer, if we would gather an abundant harvest, in autumn.

We may almost lay it down as a maxim, that THE MENTAL AND MORAL CONDITION OF AN AGRICULTURAL DISTRICT, IS IN THE RATIO OF ITS IMPROVEMENT IN HUSBANDRY. To borrow the spirit of a political saying—*as goes agriculture, so goes the state.* There is certainly much truth in the remark, that where the farming is slovenly and bad, ignorance, indolence, and vice, most generally abound; and that where agricultural improvement is most advanced, the population are most industrious, most intelligent and most moral. Knowledge begets a love of knowledge; and when a man has acquired enough of it to convince him of its utility in his business, he considers it a part of his farming capital, and he is anxious to increase his stock of it, as the readiest means of improving his condition in life, independant of the mental pleasures which it imparts. But not having acquired the requisite degree to enable him to appreciate its value, or to show him the defects of his system of management, he plods on, with listless indifference, in the ways of his fathers; and as great success, now-a-days, seldom rewards such labors, he too often becomes spiritless and dissatisfied, and relaxes into indolence, of which vice is too frequently the concomitant.

Under the existing state of things, how does it become us to act? What are we to do? Shall we fold our arms, leave agriculture to decline further, or to shift for itself, and depend upon more propitious seasons, and other Providential interpositions, to supply our wants? Shall we depend upon the cotton, rice and tobacco of the south, which constitute our almost entire exports, to pay for the foreign commodities which we consume in the north? Or shall we, animated by the enterprise and love of independence which were wont to animate our fathers—take in hand resolutely to provide abundantly for ourselves, by encouraging and enlightening agriculture, elevating its character, and stimulating it to new efforts, by suitable honors and rewards?

As regards the means of improvement, much has been done, and much is doing, by the agricultural periodicals of the day. The first of these was established at Baltimore, by John S. Skinner, in 1819; and we can now enumerate nearly twenty, that are diffusing light, awakening enterprise, and inciting to industry, in every section of our country —Probably one hundred thousand farmers, are now deriving instruction, and improving their practice, by the perusal of these journals; and it is not extravagant to say, that the benefits they are dispensing to the nation are equivalent to millions of dollars every year. But what is one hundred thousand compared to the gross agricultural population of the union?—and how much greater would be their benefits if these Journals had access to every farm house, or even to every school-house, in the state? Besides giving much that is useful in the science, or the first principles of husbandry, they are continually advertising their readers of every improvement which is being made in the practical operations of the farm—of new seeds, and plants, and the mode of cultivating them, and of every improvement in labor-saving machines. In twelve numbers of the Cultivator may be noticed more than a hundred and twenty communications, mostly from practical farmers, residing in the different states, detailing their practice in different departments of husbandry, thus making their improvements known, in a short time, to its twenty thousand patrons.

By thus concentrating, as it were in a focus, the practical knowledge of the country, and then scattering it, like the solar rays, into every corner of the land, to fructify the earth, and by thus rendering it subservient to the benefit of all, some individuals have been enabled to obtain a clear profit of fifty, one hundred, and even one hundred and fifty dollars, on an acre of corn, or an acre of Swedish turnips, who had never before obtained a profit of thirty dollars an acre from either. And the benefits of these splendid results are not confined to the individuals who effected them: they are heralded in the agricultural journals; become known all over the country; and every new and successful effort at improvement, soon has its fifty, its hundred, and its thousand imitators. Suppose, for instance, what we hope will yet prove true, that an individual should discover an effectual preventive of the ravages of the Hessian fly, or grain worm—instead of benefitting him and a few neighbors, or becoming gradually known, as in olden times, the knowledge of it would now be spread in a few days, by the agricultural periodicals, into every corner of the land, and the advantages of the discovery would thus amount to millions in a single year. So with every other improvement in husbandry. It is not the province, nor is it the study of news journals and literary editors to deal extensively in agricultural concerns. They seldom publish even the incidental notices which are designed to subserve the interests of husbandry, without a special request, and a fee in the bargain, as though *they* had no personal interest in the progress of agricultural improvement. We would infer from these premises, that every man will promote his interest, and benefit the public, by patronising and endeavoring to extend the circulation of our agricultural papers. They tend to no possible evil, while they are certainly calculated to do much public good.

Another means of facilitating agricultural improvement, is to introduce class books, into our common schools, for the senior boys, which shall teach those elementary principles of science which are indispensable to the successful practice of agriculture. A boy may be almost as easily taught to analyze soils, and to comprehend the leading principles of animal and vegetable physiology, as he can to commit to memory pages of matter, the knowledge of which seldom serves him any useful purpose in manhood. We must begin in youth, if we would bring about any material improvement in the habits of society. The good seed that is sown in the spring time of life is never lost,—it will ultimately sprout, and grow, and give its increase, as surely as the grain which we deposite in a fertile soil. The tree *will* grow as the twig is bent. Youth is the season to get instruction in the principles of the business which is to constitute the employment of life; and the more the knowledge which boys acquire in these principles, before they start in life for themselves, the more likely they are to prosper and become useful to society. The time that the senior boys in school devote to the business of the farm, will give to studies which are connected with their present and future business, an interest and an influence which will be as abiding as life.

But we would go farther in the business of agricultural instruction;—we would establish schools to teach simultaneously, both the theory and practice of agriculture. We would carry something of the theory into the primary schools, and much of the practice into the schools of science. Veterinary schools, to instruct in the anatomy and management of domestic animals, have long been established in Europe; their usefulness has been highly extolled, and their numbers are increasing. Switzerland, Prussia and France have also their schools, in which the science and practice of agriculture are taught to hundreds of young men, who are thereby enabled to manage their estates, with greater benefit to themselves and the public, or to obtain honorable and lucrative situations as managers for others. We give bounties on our fisheries, to make them a nursery of seamen; but we give none upon agriculture, which is the best nursery of freemen.—We spend millions annually to protect our commerce; but we give nothing to improve agriculture, which is the basis and support of that commerce. We protect our manufactures by a heavy tariff; yet agriculture, which furnishes the raw materials, and buys the fabricks, which the manufacturer consumes and vends, is left to protect itself. We have expended nearly three millions in this state, to aid in educating almost exclusively professional and other gentlemen; and yet we have given nothing exclusively to educate our agriculturists, who constitute the great mass of our population. And yet there is probably no employment in life capable of being more benefitted by a professional education—none in which a professional education would conduce more to the public prosperity—than that of managing our farms. A proper knowledge of soils, manures, vegetables and animals—of the agency of caloric, of moisture, of the atmosphere, and of light, in the economy of vegetable and animal growth—are all of great use to the farmer, and yet in what existing school can he acquire this knowledge, during the period of life in which he ought to obtain his practical knowledge?

All impressions of general reform, to be successful, must be first made upon the ductile minds of the younger population. The old are apt to be too obstinately wedded to their juvenile habits and prejudices. Men are apt to grow up in the creeds in which they are instructed—be they Christian, Mahomedan or Pagan—be they of good or bad husbandry. And if our youth are early instructed in the first elements of agriculture, and taught to consider it, what it truly is, an employment eminently calculated, above all others, to promote individual and national prosperity and happiness, they will aspire to honor and distinction in its labors—and will not so generally press to the cities—to the bar and the counter,—for the means of gratifying a laudable ambition. And society will reap an abundant reward from the change. We will illustrate this by an historical fact. Ernest, former Duke of Saxe Gotha, had his people instructed by compendiums of every kind of useful knowledge, including music and drawing, that were put into the hands of youth in all country schools; and which in a few years entirely changed the face of his principality; and "it is amazing," adds our author, who wrote some years afterwards, "to observe the different irradiations of genius, in this and the adjacent circles." The effect was alike beneficial in the improvement of the soil and the mind. And the example of Saxe Gotha, probably led to the excellent system of school instruction in agriculture which has since been introduced by Prussia, and most of the German states.

It has been stated, as an objection to the establishment of agricultural schools, that they would be only accessible to the rich. This objection, even if well founded, would not go to lessen their value to the state : For if we could convert a few hundred drones, as the sons of rich men may generally be termed, into working bees, the public, as well as the young men themselves, would certainly be gainers by the transformation. The complaint is that we have too many consumers, and too few producers. This would tend to restore an equilibrium: For the examples of the rich, be they good or bad, have an imposing influence on the middling and lower classes; and thus to improve the habits and morals of the rich, would be the surest way to improve the condition of society. Hence, therefore, if agricultural schools can be instrumental in annually converting a few hundred of the idle and dissipated sons of wealth—or rather in preserving them from these habits—into wholesome industrious farmers, agricultural pursuits will be more respectable and more followed; and we venture to predict, that then we shall not long continue to do, what we have done—import potatoes from Ireland and Germany, hay and oats from Scotland, eggs from France, and bread stuffs from all the countries of Europe, including the dominions of the autocrat of Russia and of the Grand Turk.

But it is not exactly true that the rich alone would find access into agricultural schools, were such established.—The rich rely upon their paternal wealth, and have not often the ambition to become useful, at least by the habits of manual labor, which would be rigidly required in such schools. The schools would be filled with the youth from all classes of society, who aspired to fortune and independence, by a manly exercise of their mental and physical powers—the young men of this description, even from the poorer classes, do obtain admission into literary institutions, and they would into agricultural ones with greater facility,—because the terms of admission here would be more reasonable—and with equal prospect of distinction and usefulness in after life. But whether these schools should be filled from the rich or poorer classes, or, as we have supposed, from all classes indiscriminately, a certain and great public good would result from their establishment: the pupils would go to swell the producing classes of society, with habits of application and usefulness, minds imbued with scientific knowledge, bodies hale and robust, and hands practiced in all the manual operations of the farm.

It verily seems to us certain, that if the importance of the subjects which we have discussed, could be justly appreciated by the community at large, every class of our citizens would concur in the propriety of a united effort to improve the condition of our husbandry, and of speedily adopting the measures we have suggested, or others equally availing, to produce the desired result.

On motion of Mr. Beekman,

Resolved, That the thanks of this convention be presented to Judge Buel, for his communication on the subject of the improvement of agriculture, and that a copy be asked for publication.

On motion of L. F. Allen, it was

Resolved, That a committee of five be appointed for the purpose of considering the propriety of introducing into our common schools, books which treat on agriculture.

The resolution was advocated by Messrs. Allen, Mann, Viele, Cheever, Bradish, Owen, Patterson, and Sibley, and opposed by Messrs. Culver and Crary. Before the question was taken, Mr. Buel offered the following substitute.

Resolved, That the introduction of elementary books upon agriculture and rural economy, into our common school libraries, as occasional class-books for boys, is considered by this convention as eminently calculated to advance agricultural improvement, to encourage industry, and to promote the moral health of society.

The substitute was supported by the mover, Mr. Crary and Mr. Patterson, and opposed by Messrs. Richards, Allen and Baldwin.

Mr. Culver offered an amendment to the substitute, which was lost; and the question being then taken on the substitute, it was lost also. The original resolution was then adopted.

The chair named the following committee: Judge E. Cowen, of Saratoga, Messrs. Allen, of Erie, Wardwell, of Jefferson, Mann, of Herkimer, and Baldwin, of Onondaga.

The following resolution was submitted by Mr Wardwell, of Jefferson, and laid on the table.

Resolved, That a committee on the culture of the sugar beet, and the manufacture of sugar therefrom, be appointed, whose duty it shall be to examine into the subject generally, and give the result of such examination at the next annual meeting of this convention.

The following resolution was submitted by Mr. Richards, of Washington, and laid on the table.

Resolved, That a committee be appointed to report to the next convention, any further information which may be collected on the subject of the grain worm.

Mr. Baldwin, of Onondaga, submitted the following, which was laid on the table.

Resolved, That in the opinion of this convention, the existing laws relating to highways in this state, are defective, and require revision by the legislature.

The convention then adjourned to meet at 4 o'clock tomorrow.

Friday, Feb. 2. 4 P. M.

On motion of Mr. Beardsley, of Otsego, it was

Resolved, That a committee of three practical and scientific agriculturists be appointed, whose duty it shall be to report to the next convention, upon the possibility and best practical method of extirpating the *Canada Thistle*, one of the most formidable enemies to successful agriculture.

Messrs. Beardsley, of Otsego, Duane, of Schenectady, and Fry, of Montgomery, were appointed said committee.

The consideration of the resolution submitted by Mr. Wardwell, on the subject of the culture of the *Sugar Beet*, &c. being called up, it was discussed, and adopted, and the following gentlemen appointed to report thereon, viz. Messrs. Wardwell, of Jefferson, Jonah T. Marshall, of St. Lawrence, and S. Cheever, of Albany,

On motion of Mr. Buel, it was

Resolved, That inasmuch as most of our wealth is derived from the cultivation of the soil, it is politic and just that a portion of our revenue should be applied to the *improvement* of the soil, and that, therefore, in the opinion of this convention, a part of the interest accruing from the investment of the surplus revenue, ought to be specially appropriated, by the legislature, to the improvement of the agriculture of the state.

Mr. Viele, from the committee appointed at the last annual state convention, under the resolution "to inquire whether in the distribution of public monies in aid of agriculture, a better mode can be devised than that of giving it to county agricultural societies to be awarded in premiums," reported to the convention,

That by reason of their being located in different parts of the state, the members of the committee had not the opportunity for meeting and consultation, but they nevertheless brought their individual minds to bear upon this important subject, and are highly gratified in being able to find on coming together at this time, that the result of their reflections had brought them all to the same conclusion. They would however express their regret that the occupation of the short time allotted them, by their duties in the State Society and Convention, have precluded them from doing the subject that justice its importance demands.

The policy of appropriating public moneys to stimulate to exertion the laboring and producing classes, and also to elicit the inventive genius of our country, has of late received much of the attention of the most enlightened and patriotic minds in this community; and as far as the committee have been able to ascertain, such attentions and reflections have almost invariably brought them to the conclusion, that the adoption of such a policy, would in its practical results be productive of the greatest benefits to the community.

That it would elevate and ennoble the character of our agricultural community—that it would rescue from ignorance, (we had almost said ignominy) this most useful class of our citizens—that would equalize in point of honor and respect the different occupations and professions—that it would improve not only the soil but the mind—that it would vastly increase the products of the earth, and by calling forth the inventive talent of the country, lessen the expense of production and manufacture—that it would enhance the value of our real estate by doubling its productions—that it would be productive in a degree, of a spirit of contentment, which would arrest the tide of emigration, that is abstracting our population, our labor and our wealth—that instead of impoverishing, it would enrich the public treasure, by increasing the taxable property of our state, and increasing those productions which require transportation, and consequently the revenue derived from our public works—in a word, that it would redound to the honor and promote the prosperity of all and every interest in this great state, the committee cannot entertain a doubt.

In coming to this conclusion, they do not rely upon what has perhaps too justly been termed "vain theory and idle speculation," but they have consulted the experience and practical results of those countries and states, who (with "shame and confusion of face" we acknowledge) have gone ahead and taken the lead of our boasted "empire" in this march of improvement.

Improvement in this branch of domestic industry is a distinguishing feature between civilization and barbarism, liberty and despotism—wealth and poverty—moral and intellectual advancement and mental degradation. Thus we see the more liberal and enlightened nations of the eastern continent encouraging and patronising this great interest, which lies at the foundation of all true national greatness, and under proper attention is the prolific source of a nation's prosperity and wealth. Most of the governments of Europe have set apart a portion of the public bounty, and adopted some system, to increase the productiveness and enhance the value of well applied labor.

In France great encouragement is given to the cultivation of the vine and the sugar beet—two objects to them, of great national importance. Germany has proved the wisdom of her councils, by the establishment and patronage of schools, devoted to scientific and practical agriculture. Prussia, too, has shown that she is not asleep to her interest, by the introduction at the public expense, of the science and practice of this invaluable art into all her public schools. On the other hand, the despotism of Russia, neglecting alike the improvement of her agriculture and her semi-barbarous population, labors studiously to keep her boors and serfs in a state of vassalage and mental degradation; and chooses rather to expend the treasure which legitimately belongs to the people, in a forty years war with the Georgians and Circassians, with a view ultimately to wrest from Great Britain her most profitable trade with the East Indies. Great Britain, always alive to what promotes her interests, has adopted an enlightened policy on this subject, and Scotland, by means of her societies and premiums, has brought that romantic country,

> "Where wild woods grow and rivers ro'
> Wi' mony a hill between,"

into a state of improvement and cultivation that challenges the admiration of the world.

While these efforts have been making abroad, and while this improvement has been going on, our own country, favored of Providence above all others, in the richness of her soil and the enterprize of her citizens, has been retrograding, or at all events, remaining stationary, in the condition of her agriculture.

The consequence has been, that with all our boasted *independence*, and with all our natural advantages of soil, climate, and the industry of our citizens, we have been *dependent* upon these foreign despotisms for the means of subsistence. To say nothing of luxuries—in a time of almost universal peace and prosperity, even the "staff of life" has been suffered to fall from under us, and we obliged to trust to one, "that while we lean upon it, it pierces us." We allude to the most astonishing and humiliating fact, that our country, the most fertile and productive of "Gods heritage to man," has been under the necessity—and is even at this time importing her bread-stuffs, forage &c. to support a population essentially agricultural, in a country the best adapted by nature to the growing of grain of any in the world.

The committee however congratulate themselves and the community, that public attention is being more directed to this subject. The people generally are arousing from their stupor, and public opinion, that mighty engine of all moral and civil reform, the resistance of whose breath is as fatal as the deadly Simoon of Africa, is beginning to move, and we have good reason to believe it will advance until its influence shall reach our legislative halls, and induce those entrusted with the public weal, to see to it—to protect, encourage, and advance it—instead of spending the people's time and money in useless political manouvreing; in making political harangues for out-door effect.

Among the evidences we have that "the people are a coming" on this subject is, that in many of the states of the union, legislative action has been already had, and an enlightened policy adopted, which has already been production of much good.

Among the first to advance in this matter was the state of Massachusetts. She encouraged some years since the establishment of County Societies, and sustained them by liberal appropriations. The law under which they organized expired not long since, and she has proved her devotion to this cause by a renewal of the same. This is conclusive evidence to her, that the policy is sound and salutary, and in perfect accordance with the views and wishes of her enterprising and thrifty population. The State of Maine has also given an example of great wisdom and liberality in recent efforts to improve her agriculture. The bounty which she this year pays to her citizens, to encourage the culture of wheat alone, will draw from the treasury more than all the expenditures which the "Empire State" has ever made directly in aid of agriculture.

Several of the other states have taken measures for the establishment of agricultural schools, and others have offered liberal bounties to encourage various useful and lucrative branches of home industry, as the cultivation of the sugar beet, the mulberry, and the production of silk.

The indications of public sentiment in our own state, we are happy in stating, are as far as we have been able to ascertain, in favor of a judicious and liberal appropriation by the state, to promote and advance the condition of her languishing agriculture.

As to the question raised by the resolution under which the committee act, we would remark; that although the establishment of schools, especially devoted to the education of young men in scientific and practical agriculture, is a matter of very great importance, demanding upon every principle of justice and expediency, the attention and patronage of the state, still they believe that more *immediate* and more general benefit would be derived from the establishment of a state board of agriculture, with branch societies in the several counties of this state; each having the power and authority, under proper regulations and restrictions, of awarding premiums for the production of the greatest results with the least expense in tillage; and also for the invention of useful and labor-saving implements for production, or machinery for manufacturing.

By this mode of distribution an immediate advantage would be reaped by the present generation of farmers, which perhaps no other means would reach. There is a class, we regret to say, in this community, so "wise in their own conceit" as to be above all improvement, in this most complicated and imperfectly understood art. So riveted are they to their old practices, that every improvement is denounced as an innovation. Even the most palpable errors in practical husbandry, having the sanction of ages, and having been handed down from sire to son for "time the memory of man runneth not to the contrary," they are loth to acknowledge, and slow to correct. This class composing the most illiterate of the community, and having passed the meridian of life without cultivating their minds, would derive little or no advantage from the slow but sure process of diffusing knowledge by means of schools. But by means of societies, distributing premiums, the whole community would be excited and vie with each other to excel in all that relates to their occupation. The effect woud be to improve this class, not by reason of themselves, but in spite of themselves. Every step in improvement would add not only to individual but to national wealth.

The law of 1819, "to improve the agriculture of the state," although limited in its operation and duration, was productive of a vast amount of good to the people of this state. Although imperfectly, and in many cases, badly administered, as all new undertakings are liable to be, it gave an impulse to useful enterprize and improvement, which is felt and acknowledged up to this day. It improved our farm stock—farm implements—farm crops and modes of culture. That law involved a public expenditure of about thirty thousand dollars, and the committee are induced to believe that no like sum has ever been expended from the public treasury with greater public advantage. The advantages derived from it are now palpable, and acknowledged by all intelligent men who have reflected on the subject. It is the opinion of men whose judgment is entitled to the greatest respect, that the expenditure has been more than thrice returned to the treasury, in the form of canal tolls upon extra products of the soil, which it virtually created.

While, therefore, we are unwilling to say that any *better* mode can be devised, in the distribution of public monies than that of awarding it in premiums, still we confidently hope that something also will be done for the rising agricultural generation, by the endowment of schools, where the sons of farmers can be educated in a manner suitable to their occupation, and taught those branches of science which are applicable to those arts and that business, which they are destined to pursue through life. It is only through schools that we can ever hope to elevate the intellectual character of our yeomanry. It is to the youth of the country that we must look, for a simultaneous improvement of the soil and the mind. They will soon be our Legislators, our Judges and our Jurors. They are to be the future guardians of our liberties, and all those invaluable privileges which we enjoy.—Is it not important then that they should be properly qualified by education, for the discharge of these sacred trusts? Five-sixths of the population of the country are engaged in agriculture, and in a measure deprived of the means of a suitable education. In view of these facts the committee believe that it would be the dictate of wisdom, to make suitable provision for the education and diffusion of knowledge among this class of our citizens. On the score of justice, they have a right to demand it. As a matter of expediency, it does not seem to admit of a question.

In conclusion the committee would respond to the language of the resolution which created them, that in their opinion, there is no way that public money can be appropriated *more* beneficial to the cause of agriculture than by awarding it in premiums, and they confidently hope that the legislature will adopt a policy worthy of our great state, and discard that "penny wise and pound foolish" system which has hitherto rejected all applications on this subject.

They, therefore, recommended to the convention the adoption of the following resolution,—

Resolved, That in the opinion of this convention, an appropriation ought to be made from the public treasury—

1. For the purpose of establishing a State Board of Agriculture;
2. For the improvement of agriculture through agricultural societies to be established in the several counties;
3. For the endowment of a state agricultural school or schools.

The report was accepted, and the resolution being under consideration, it was, on motion of Mr. Crary, of Washington, divided; and the first numbers thereof, recommending an appropriation of public monies for establishing a central board of agriculture, and county societies, was passed unanimously. On the last number of the resolution, recommending the appropriation of monies towards the establishment of schools of agriculture, considerable debate ensued, in which Mr. Crary opposed, and Messrs. Mann, Allen, Buel, Baldwin, and Gen. Root, of Delaware, supported the proposition; and the entire resolution was finally adopted by an almost unanimous vote.

On motion of Mr. Beekman, the president was desired to read a letter addressed to him by Willis Gaylord, which having been read, a copy thereof was requested for publication, and is as follows:

Otisco, Onondaga County, Jany. 29, 1838.

J. R. Lawrence, Esq.—

Dear Sir,—I last evening received the Evening Journal of the 24th, and have only one apology to make in answer to the query it contained. Though I knew, at the time of receiving your last kind letter requesting the draft of a bill and report, that there were multitudes who could perform the service as well, and perhaps better than I could, yet as it was a subject in which I believed the public was deeply interested, I determined to do what I could, and had commenced throwing my ideas on the matter together with the intention of reducing them to form thereafter, when I was taken with a weakness and partial inflamation of the eyes, which has effectually prevented any further progress. Even this is written with difficulty, and must be finished at intervals, and probably contrary to what might be deemed prudence where the eyes are concerned.

Soon after I received yours, I addressed a letter to Col. Voorhees, and received an answer, going into the details of his plan somewhat at length, which, with some remarks on the system proposed, I presume, will appear in the Genesee Farmer, of this week. I can see no reason why the plan of experimental farms may not be connected with County Societies, or why such farms should have any influence in preventing aid from the treasury of the state, to such societies, and the Col. I think is of the same mind. I have been looking over the law of 1819, and think it might be safely adopted as the base of a new one with one or two exceptions. My ideas on the subject are about these—

I would have a sum of money appropriated for this purpose from the treasury; say for form sake, 100 dollars for each member of assembly; or 400 to this county. This money should be at the service of the county society on condition that the society raised by voluntary subscription one half that sum, (the old law allowed only as much as was raised by the subscription) or in the same proportion for any smaller sum subscribed; so that if $200 was raised by subscription, the sum to distribute would be $600; and so in proportion. *I would not have the choice of officers confined to practical farmers;* and this I think was one of the most fatal features of the old law; for experience proves that they are not the most fit persons to manage concerns of that kind. In superintending the ploughing; in estimating the qualities of stock, or the productions of the soil, the practical farmer is at home; but in conducting the affairs of such societies they usually fail. The choice of officers of the society should therefore be unfettered. I would have no money taken from the treasury unless societies were formed and in actual operation, and the certificate of the treasurer of the society should state that the money subscribed was actually in his possession before he could draw from the treasury. The state therefore would have every security that the money granted would be carefully appropriated, and whatever the sum granted might be, if no societies were formed under the law, no money of course could be taken from the treasury.

The act as amended in 1822, authorised the supervisors to raise and expend money as they pleased for the benefit of agriculture and domestic industry. This I think was preposterous. The society should have the expenditure of all the moneys raised; for if there is not spirit enough in any county to form a society, it is idle, and worse than idle, to levy a tax on the inhabitants for distribution by supervisors.

The societies must embrace the plan of *annual shows*, and the *distribution of premiums*, or no legislation will be productive of benefit. These constitute the springs that must move the whole machinery, without these nothing can or will be done.

A general law embracing the formation of associations for experimental farms, might also be passed, either in connection with, or independent of the county societies. If such farms were established near the centre of the county, they might serve as places where the annual fairs might be held as well as farms on which the most improved systems of husbandry could be exhibited. I have no doubt that such a farm properly conducted might be a profitable speculation to the stockholders, as well as beneficial to the community; witness the sales of improved animals, made by Bement and others, at prices which would justify the greatest care and attention.

You have undoubtedly seen by this county papers, that a meeting is to be held this day at Syracuse, for the formation of a County Agricultural Society. I trust it will be well attended, and only regret that I could not have been present. This county should have a society, whether aided by the state or not, that will be active and efficient. We have the means, and we must have the spirit. But I think it can be demonstrated, that every dollar the state pays out, to promote agriculture, will be returned to the treasury eventually fourfold.

From the Governor's not introducing the subject into his message as he usually has done, I was apprehensive the whole matter would fall through, and no committee be appointed; and even now I do not know who the members of the committee are, except that L. F. Allen is chairman. I think this a most fortunate selection, as there are few men more thoroughly acquainted with the subject in all its bearings, and more capable of taking enlarged and liberal views of the matter, than he. With your aid I am confident justice will be done; and whether we get such a law passed, or whether old prejudices will operate so far as to defeat the object, the friends of the best interests of the state will at least have the consciousness that they have done their duty.

I remain yours respectfully,
WILLIS GAYLORD.

On motion of Mr. Baldwin, it was

Resolved, That this convention memorialize the present legislature for an appropriation for the objects enumerated in the resolution just adopted.

Messrs. S. Cheever, F. Rotch and J. P. Beekman were appointed a committee to draw up said memorial.

On motion of Mr. Randall, it was

Resolved, That a committee of three be appointed to prepare the proceedings of this convention for publication; and that said committee furnish the publishers of The Cultivator and Genesee Farmer with copies of the same for publication.

Messrs. Randall, Buel and Baldwin were appointed said committee.

The following resolutions were submitted by Mr. Buel, and adopted.

Resolved, That the introduction of foreign seeds and plants, through our consuls, public ships and merchant vessels, and the establishment of an office at the seat of the general government, for the reception and distribution of such seeds and plants, would conduce to the improvement of our farms and gardens; therefore,

Resolved further, that this convention respectfully request the Senators and Representatives of this state, in the Congress of the United States, to use their exertions for the passage of a law for procuring such seeds and plants, and the establishment of such office, to be under the supervison of the commissioner of the patent office, or of such other responsible officer as congress in its wisdom may designate.

Copies of these resolutions were directed to be signed by the presiding officer of the convention, and forwarded to our senators and representatives in congress.

The convention then took up the resolution offered by Mr. Baldwin yesterday, "to petition the legislature to alter the existing laws in relation to highways," and adopted the same.

On motion of Mr. Richards, the committee appointed last year on the subject of the grain worm, were requested to continue their investigations, and to report thereon at the next convention.

On motion of Mr. Baldwin,

Resolved, That the thanks of this convention be presented to the Hon. the Assembly, for the use of their chamber for this convention.

On motion of Mr. Baldwin,

Resolved, That the thanks of this convention be presented to the president and vice-presidents, for the able and dignified manner in which they have presided over its deliberations, and to the secretaries thereof, for the performance of their duty.

On motion of Mr. Grove,

Resolved, That a state agricultural convention be appointed to be held at the City Hall in the city of Albany, on the first Wednesday in Feb. next.

The convention then adjourned without day.

JAMES R. LAWRENCE, *President*.
HENRY S. RANDALL, *Secretary*.

Gen. Root's Remarks.

In the agricultural convention, a resolution being under consideration for memorializing the legislature, *to appropriate a part of the interest of the surplus fund towards an agricultural school or schools*, Gen. Root, of Delaware, rose in support of the resolution, and offered the following, among other reasons, in support of the propiety of such an appropriation.

Gen. Root proceeded to state, that the fund in question originated in a surplus revenue, which had grown out of proceeds of the sales of the public lands. It had appeared by the treasury reports, that the customs and other sources of revenue, exclusive of the public lands, had been, for the last four or five years, just about enough to complete the extinction of the public debt, and meet the ordinary expenses of government. The avails of the public lands, for the last five years, very nearly gave the exact amount of the surplus, directed by the act of congress to be distributed among the several states, to be deposited with them, and to be redrawn, when needed, by the secretary of the treasury. By the late act, postponing the payment of the fourth instalment, it is provided, that the secretary shall not draw upon the states, until directed so to do by act of congress. This act will virtually give to the states the absolute dominion over this money. The only question that remains is, how the interest arising from this fund shall be appropriated. By the bill, commonly called Mr. Clay's land bill, which some years ago passed both houses of congress, and by a large majority in each house, it was provided, that the nett proceeds of the public lands, for five years, should be distributed among the several states, for the purposes of EDUCATION AND INTERNAL IMPROVEMENTS. This bill did not become a law, as it was withheld by the president, and not returned with his objections, till the meeting of a new congress. The people, however, had expressed their will in regard to the disposition of this fund, in the only way the constitution of their own choice had provided for the expression of that will,—that is, through and by their representatives. That national domain, which was constituted by cessions of the several states having claims to unseated or crown lands, as they were then called, and lying within the limits of their respective charters, belonged to all the states then existing, or thereafter to be admitted into the union. It belonged to the whole, as a fund pledged for the redemption of the debt incurred by the war of the revolution; and after the extinguishment of that debt, its proceeds rightfully belonged to the states, to be divided among them, according to their federal numbers. The people, through and by their representations, have declared, that the interest arising from this fund, so distributed, ought to be applied to purposes of education and internal improvement, and we have it from very high authority, that the will of the people is the supreme law.

This state has additional reasons, and stronger perhaps than any other state in the union, to apply the whole of this fund to the purposes of education. We have already our system of internal improvements, with an accumulating fund for their onward and progressive march. The legislature may, therefore, be spared any pressing importunities for such objects. And further, the people of this state have solemnly declared in their constitution ratified by them, that the proceeds of its own public lands shall be permanently devoted to the support of common schools. As the people of this state have, by solemn constitutional enactment, thus proclaimed their will in regard to their exclusive domain, we have reason to believe that their representatives, in the state legislature, will feel, that they are acting in obedience to the will of their constituents, by appropriating the whole of this fund to the various branches and schools of education.

The only remaining question to be examined, said Gen. Root, is whether an agricultural school, including, of course, the art as well as the science of horticulture, would come within the provision of common schools, or of academic schools, in which are taught the higher branches of an English education. The education of the rising generation, he said, had always been held by him as a matter of public concern and public care. The whole people—the political community, were deeply interested in educating its children, and fitting them for the various duties and avocations they may be required to perform. The training and development of the moral and intellectual powers are all-important,—so are the exercise, guidance and discipline of the physical powers. If it is the part of a common school education "to teach the young idea how to shoot," it is no less so to direct the tender limbs and muscles how to exercise. By exercise, a vigorous exercise of the muscular powers, the mental are undoubtedly improved. The exercise of the one, imparts a vigor not only to itself, but to the other. And are not the rural exercises pertaining to the field, or the garden, better calculated to give strength to both, than the playful sports usual with school boys?

Gen. Root then adverted to the propriety of annexing to our academies, or to some of them where it could be conveniently obtained, a piece of ground, if not sufficient for extensive agricultural, yet ample for horticultural pursuits. Chemistry, geology, mineralogy and botany, are among the higher branches of an English education, which entitle an institution to draw for its student a distributive share from the literature fund. Is not a practical application of these sciences necessary to fix them upon the understanding, and make them enduring upon the memory? Not more necessary are maps and globes to the young students in geography and astronomy, than a practical observation of the soil, the seeds, and the growth of plants, and the use of the various implements of husbandry and gardening, are to the student in rural labor. Natural philosophy, too, cannot attain its highest elevation, cloistered within academic walls. Let its votaries learn to guide the plough, and till the furrowed glebe, and they may vie in vigorous and manly thought and action with the peripatetic and gymnastic youth of ancient Greece.

Gen. Root concluded by expressing a hope, that the resolution would meet the decided approbation of the convention—that a respectful petition be prepared and presented to the legislature, and that its prayer would be granted by that honorable body.

In Assembly, February 10, 1838.

Report,

Of the committee on agriculture, on the memorial of the State Agricultural Convention assembled in Albany on the first day of February, instant.

Mr. L. F. Allen, from the committee on agriculture, to whom was referred the memorial of the State Agricultural Convention assembled in Albany on the first day of February, instant, reports:

Although the duties of the committee on agriculture have oftentimes been considered rather nominal than active, yet your committee, on a review of past years, and a careful examination of the present condition of the state, have come to the conclusion that a serious responsibility, at this time, rests upon them; that they are charged with some of the highest duties which devolve upon the legislature of a state—the guardianship of that primary branch of industry which is the source of our prosperity and greatness, and our sure dependence in times of public peril and and misfortune. Politicians may speculate upon the influence which free institutions, or a partizan administration, may have upon the prosperity of a country; commercial men may extol the advantages of an extended foreign commerce; manufacturers may claim pre-eminence in conferring independence upon their country; and literature may arrogate the exclusive credit of rendering a community enlightened and polished; yet, after all, agriculture constitutes the broad base upon which the whole superstructure of society depends for support. If that languishes, either for want of the protection and patronage of the constituted authorities, or from the inattention and lack of intelligence in its rural population, the government becomes embarrassed, commerce crippled, and manufactures paralyzed. A maritime war may sweep our commerce from the ocean; our manufactures may sink for want of a market for their fabrics, as they have done; but agriculture never disappoints our hopes, while we continue to enjoy the blessings of a kind Providence, whose favor it is alike our duty and our interest to propitiate, by prudent forethought and dutiful submission to all his requirements. The soil, under judicious management, never withholds the tribute of reward to those who humbly devote themselves to its culture, and place upon it their only sure reliance. Upon this, then, we ought to bestow our special attention, our protecting care. These truths have been amply illustrated and established in the experience of the two last years. Your committee are persuaded that the condition of the agriculture of any country affords a safe criterion whereby to judge, not only of its general prosperity, but of the social and moral condition of its population.

The recollections of the age will serve to show, that the relative condition of our agriculture and that of many of the countries of Europe has undergone a remarkable change within the last forty years. While the latter has been increasing, ours has been diminishing in its products. About the commencement of the present century the exportation of bread stuffs and other provisions, from the northern and middle states, amounted, annually, to twelve or fourteen millions of dollars, principally to the continent of Europe. In the two last years, instead of exporting provisions to Europe, as formerly, we have imported from thence bread stuffs to the amount of seven or eight millions of dollars. These facts conclusively show, that the agricultural products of Europe have greatly increased, while ours have been diminishing, in proportion to our population, notwithstanding the vast accession of fertile virgin soil which has been constantly enlarging our borders. Whence this great change but from a neglect, on our part, to nurture this great branch of national industry; and a diligent and constant endeavor, on the part of the governments and people of Europe, to improve it? We have the most ample evidence that the efforts of our cotemporaries on the old continent have been crowned with abundant success. France and Germany have made great advances in agricultural improvement. The once barren sands of Brandenburgh, and the no less unproductive heaths of Prussia, are now covered, through the active efforts of the Prussian government, with plentiful harvests of the finest grain in the world. The soil of England has been made to more than double its products within the last sixty years; and Scotland has quadrupled her agricultural products since the termination of our revolutionary war.

While such has been the recent progress of agricultural improvement in Europe, what has been our progress in husbandry? Has it not been retrograde? Have not our cultivated lands been generally deteriorating, under an exhausting system of husbandry? and have not large tracts, once fertile, on the Atlantic border of our country, been absolutely abandoned, as unprofitable for culture, on account of the sterility produced by our bad husbandry?

Under the view of the subject which these facts present, the committee feel it their duty to press upon the consideration of the legislature, who are delegated to take care of the public weal, an investigation into the the causes which have led to this great, this alarming change, in the relative condition of the two continents; and to urge them to adopt prompt and efficient means, not to repress the European spirit, which has done so much good to the human family, but to transfuse a portion of that spirit into our own population, and to raise the character of our agri culture, as we can and ought to do, to the level of that of any country on the globe. Fortunately, we are not left in doubt as to the prominent means of effecting this desirable object. Other governments have made the experiment for us; have set us the example, and in a measure demonstrated the certainty of success. Those governments have patronized and aided this noble art, by protection and rewards; by instruction, in the primary schools, in the elementary principles of husbandry; by national boards of agriculture; by agricultural surveys, and by schools of scientific and practical instruction in the diseases and management of domestic animals, and in the business of agriculture generally.

The state of Massachusetts was among the first to encourage the establishment of agricultural societies, and to dispense to them the public bounty. Her continuing to persevere in this policy to the present time, by a renewal of the law making an annual and liberal appropriation to this object, is at once an evidence that she has found such expenditure salutary, and in perfect unison with the feelings and wishes of her enlightened population.

The state of Maine has also given an example of great liberality and wisdom, in recent efforts to improve her agriculture. The bounty which she this year pays to her citizens, to encourage the culture of wheat alone, will draw from the treasury a greater sum, than all the expenditures, which the " empire state " has made *directly* in aid of *her* agriculture, put together.

Several of the states have likewise, with a view to encourage a useful and lucrative branch of home industry, offered liberal bounties for the cultivation of the mulberry, and the production of silk. A slight reference to the proceedings of the current legislatures of several of our sister states, at this moment, may show the position which our own proud state should assume on this important subject.

A bill is now before the legislature of Massachusetts for giving a bounty to her citizens for the production of wheat.

A bill is in discussion in the legislature of Kentucky to establish a board of agriculture, and state and county societies.

A bill is before the legislature of Maryland to establish and patronize agricultural schools, &c.

A bill is under consideration in the young and enterprising state of Michigan, for the establishment of state and county agricultural societies, with appropriations from the state funds for their support.

And even Wisconsin, that wild, though fertile and rapidly increasing territory of the great west, is engaged in the same laudable work.

Nor do we lack a useful lesson of instruction at home. The law passed in 1819, " to improve the agriculture of this state," did do what its title purported; it did IMPROVE the agriculture of this state. It improved our farm stock, our farm implements, our farm crops, and modes of culture; and it gave a new impulse to useful enterprize and improvement. And although the manner of its execution was in many cases faulty, as all new experiments are liable to be in the outset; yet it effected a great public good. That law involved a public expenditure of twenty-five or thirty thousand dollars, and no like sum, your committee are induced to believe, has been expended from the state treasury with greater public advantage. Its benefits are now palpable, and are acknowledged by all intelligent men. Indeed, it has been stated, upon no slight grounds, that the expenditure has been more than thrice returned to the treasury, in the form of canal tolls upon the extra products of the soil, which it virtually created.

There is another subject to which the committee deem it proper to call the attention of the legislature. The insect denominated the grain worm, has, for several years, been greatly destructive to the wheat crop in the northern and north-eastern counties of the state. It is progressing south and west, and threatens to cut off, or at least seriously to diminish, the great staple of our soil, and the source of much of our wealth. If the attention of naturalists, and the critical observation of practical farmers, were directed to the character and habits of this insect, by offers of a liberal bounty for the discovery of an efficient preventive of its depredations, it is believed that great public benefit might result from the measure, while it seems certain that no injury could ensue from it.

Your committee believe that in all the arts of productive labor, and particularly in agriculture, it is highly important, to the attainment of excellence, to commence instruction in the primary schools. And as we now have published, in our state, agricultural journals of as high and useful character as are published in the world, and at a price less than one-fourth the cost of an equal quantity of matter in a book form, they consider their introduction into our common schools as occasional class books for our youth, a cheap and efficient means of improving both the mind and the soil.

From the best consideration which the committee have been able to give to the important matters which come within the purview of their duties, they have come to the unanimous conclusion, that the time has arrived, when the public interest, and the popular will alike require the exercise of legislative wisdom, and legislative bounty, to improve the condition of our agriculture; the business, as has been already remarked, which gives employment to the mass of our population, and which is the main source of prosperity to all the other classes of society. The committee, therefore, recommend that, with a view of promoting the desired improvement, a law be enacted to organize a state board of agriculture, and to establish agricultural societies in the several counties of this state; and that an annual expenditure of 25,000 dollars be authorized, for five years, with suitable provisions and under proper restrictions, to improve the agriculture of this state. The committee have prepared a bill in accordance with their views upon this subject, and have directed their chairman to ask leave to present the same.

An Act

TO IMPROVE THE AGRICULTURE OF THIS STATE.

The People of the State of New-York, represented in Senate and Assembly, do enact as follows:

§ 1. That the sum of twenty thousand dollars per annum shall be, and hereby is appropriated, for the term of five years, for the promotion of agriculture and household manufactures, in the several counties of this state, in the manner following, to wit: To the county of Albany five hundred and twenty-one dollars; to the county of Allegany, three hundred and forty-eight dollars; to the county of Broome, one hundred and seventy-four dollars; to the county of Cattaraugus, three hundred and forty-eight dollars; to the county of Cayuga, five hundred and twenty-one dollars; to the county of Chautauque, five hundred and twenty-one dollars; to the county of Chemung, one hundred and seventy-four dollars; to the county of Chenango, five hundred and twenty-one dollars; to the county of Clinton, one hundred and seventy-four dollars; to the county of Columbia, five hundred and twenty-one dollars; to the county of Cortland, three hundred and forty-eight dollars; to the county of Delaware, three hundred and forty-eight dollars; to the county of Dutchess, five hundred and twenty-one dollars; to the county of Erie, five hundred and twenty-one dollars; to the county of Essex, one hundred and seventy-four dollars; to the county of Franklin, one hundred and seventy-four dollars; to the county of Genesee, six hundred and ninety-five dollars; to the county of Greene, three hundred and forty-eight dollars; to the county of Herkimer, three hundred and forty-eight dollars; to the county of Jefferson, five hundred and twenty-one dollars; to the county of Kings, three hundred and forty-eight dollars; to the county of Lewis, one hundred and seventy-four dollars; to the county of Livingston, three hundred and forty-eight dollars; to the county of Madison, five hundred and twenty-one dollars; to the county of Monroe, five hundred and twenty-one dollars; to the county of Montgomery, five hundred and twenty-one dollars; to the county of Niagara, three hundred and forty-eight dollars; to the county of Oneida, six hundred and ninety-five dollars; to the county of Onondaga, six hundred and ninety-five dollars; to the county of Ontario, five hundred and twenty-one dollars; to the county of Orange, five hundred and twenty-one dollars; to the county of Orleans, one hundred and seventy-four dollars; to the county of Oswego, three hundred and forty-eight dollars; to the county of Otsego, five hundred and twenty-one dollars; to the county of Putnam, one hundred and seventy-four dollars; to the county of Queens, one hundred and seventy-four dollars; to the county of Rensselaer, five hundred and twenty-one dollars; to the county of Richmond, one hundred and seventy-four dollars; to the county of Rockland, one hundred and seventy-four dollars; to the county of St. Lawrence, three hundred and forty-eight dollars; to the county of Saratoga, three hundred and forty-eight dollars; to the county of Schenectady, one hundred and seventy-four dollars; to the county of Schoharie, three hundred and forty-eight dollars; to the county of Seneca, one hundred and seventy-four dollars; to the county of Steuben, five hundred and twenty-one dollars; to the county of Suffolk, three hundred and forty-eight dollars; to the county of Sullivan, one hundred and seventy-four dollars; to the county of Tioga, one hundred and seventy-four dollars; to the county of Tompkins, three hundred and forty-eight dollars; to the county of Ulster, three hundred and fifty dollars; to the county of Warren, one hundred and seventy-five dollars; to the county of Washington, three hundred and fifty dollars; to the county of Wayne, three hundred and fifty dollars; to the county of Westchester, three hundred and fifty dollars; to the county of Yates, one hundred and seventy-four dollars.

§ 2. That when an agricultural society shall be formed in any county, or in two contiguous counties, and the members thereof shall annually procure, or raise by voluntary subscription, any sum of money, the president and treasurer shall make and subscribe an affidavit of the facts of the formation of such society, and of their having raised a certain sum, specifying the amount thereof, which affidavit shall be filed with the comptroller of this state, who shall draw his warrant on the treasurer for a sum equal to double the amount of such voluntary subscription, not, however, exceeding the amount to which such county or counties would be entitled, according to the apportionment aforesaid.

§ 3. That the several agricultural societies which shall be formed in this state, during the continuance of this act, shall annually elect such and so many officers as they shall deem proper, all of whom shall be actually engaged in carrying on the business of farming; none of whom, however, shall receive any emolument from his office; and it shall be the duty of such officers annually to regulate and award premiums on such articles, productions and improvements, as they may deem best calculated to promote the agricultural and household manufacturing interests of this state; having especial reference to the nett profits which accrue, or are likely to accrue, from the mode of raising the crop or stock, or the fabrication of the article thus offered, with the intention that the reward shall be given for the most economical or profitable mode of competition: Provided always, that no individual shall receive more than two premiums at any anniversary meeting, nor more than one first and one second premium at any subsequent time upon the same animal, and that no person shall receive any premium from an awarding committee of which he is a member thereof: And provided further, that before any premium shall be delivered, the person claiming the same, or to whom the same may be awarded, shall deliver in writing to the president of the society, as accurate a description of the process in preparing the soil, including the quantity and quality of manure applied, and in raising the crop, or feeding the animal, as may be; and also of the expense and product of the crop, or of increase in value of the animal, with the view of showing accurately the profit of cultivating the crop, or of feeding or fattening the animal.

§ 4. That if an agricultural society shall not be organized in any county, or shall neglect to raise by voluntary subscription, a sum which shall entitle them to the apportionment made to said county by this act, the board of supervisors of said county are hereby empowered, at their pleasure, during the continuance of this act, to raise annually, in the manner the contingent charges of said county are required to be raised, a sum equal to one half the amount hereby appropriated to said county. And whenever the president of said board of supervisors shall certify to the comptroller that such board of supervisors have resolved to raise such sum, it shall be the duty of the comptroller to draw his warrant on the treasurer of the state, in favor of the treasurer of such county, for the sum appropriated for said county by the first section of this act.

§ 5. That it shall be the duty of the supervisors of every such county, to cause all the money so raised and received for agricultural improvement, to be paid and expended at an annual agricultural exhibition, to be held in such county, at such time as they shall appoint, in such manner as shall in their judgment best promote the legitimate object of this act, and subject to all the provisions contained in the third section hereof.

§ 6. That the several presidents of the said societies, and of the boards of supervisors, who shall receive or expend any of the moneys hereby appropriated, shall annually, in the month of December, transmit all such reports or returns as they are required to demand and receive, to the secretary of the state board of agriculture, hereafter named and organized, together with an abstract of their proceedings, exhibiting a detailed account of the expenditure of all the moneys which shall come into their hands under this act, and stating to whom and for what purpose paid, with the vouchers thereof.

§ 7. There shall be organized a state board of agriculture to consist of five members, who shall hold their offices for five years from the second Tuesday of February, one thousand eight hundred and thirty-eight, and shall receive while necessarily employed in the duties enjoined by this act, the same compensation as members of the legislature. They may choose such officers as they may deem necessary, and shall hold quarter-yearly meetings in the city of Albany on the first Tuesdays in February, May, August and November; and may also meet at such other times as may be found expedient to fulfil the duties hereafter enjoined upon them.

§ 8. There shall be assigned for the meetings of the state board of agriculture, and as a museum for models, geological specimens, and agricultural productions, a suitable apartment in the state buildings now erecting; which room and museum shall be kept in order by the secretary, or by some person to be appointed by the board, and shall at all reasonable hours be open and accessible to the public without charge.

§ 9. It shall be the duty of the state board of agriculture to examine all reports and returns made by the presidents of the county agricultural societies, and boards of agriculture; to select, for publication, such of them, and such other essays as they may judge advisable; and shall annually publish a volume, to be distributed in the several counties of this state, by the county agricultural societies, or by the boards of supervisors thereof: And they shall examine, when in session, and determine by practical experiment on the merits of all new farm implements or machinery offered for their examination, and may award discretionary premiums, upon such as may be found truly meritorious and deserving of public patronage, provided the whole amount expended in any one year shall not exceed the sum of one thousand dollars for that purpose; and provided further, that no such premium shall be delivered to the person claiming the same, until he has deposited with the board a model of his implement, machine or improvement.

§ 10. There shall be deposited in the room assigned to the board, a complete set of mineralogical and geological specimens, properly arranged and labelled, from the collections now being made by the geological corps in the public employ; specimens of choice or rare agricultural productions, models of implements, drawings of choice animals, books, and other articles which may be presented to the museum, a registry of all which shall be made by the secretary, and open to the public inspection.

§ 11. The said state board of agriculture shall report annually to the legislature, in the month of January, a statement of their expenditures and of their proceedings during the previous year; and also all matters that they may deem calculated to promote the improvement of agriculture and of household industry.

§ 12. A reward of five hundred dollars shall be and is hereby offered to any person who shall discover and will communicate to the state board of agriculture, for the public benefit, a sure and efficient preventive of the depredations of the insect denominated the Grain Worm; the efficacy of the said preventive to be tested by the said board during at least one year, and satisfactorily confirmed before the said award shall be given; and if the discovery shall prove but a partial remedy of the evil, it is made discretionary with the said board, or a majority of them, to award such part of the sum hereby appropriated as its importance may seem to justify.

§ 13. That the treasurer of the state shall annually pay on the warrant of the comptroller to the said state board of agriculture, the sum of five thousand dollars, to enable them to pay the aforesaid premium; to purchase and distribute such useful seeds as they may deem proper; to publish an annual volume, and to defray such other necessary expenses to promote the object of this act, as are not otherwise provided for; and the said board shall annually account with the comptroller for the expenditure of this money.

§ 14. That the presidents of the several county societies, or delegates to be chosen by them annually for the purpose, shall be ex-officio members of the New-York State Agricultural Society.

§ 15. The board of agriculture, constituted as aforesaid, shall have the authority in their discretion, to award premiums for the production of extraordinary and valuable crops of grain; beet root, and sugar manufactured from the same; mulberry orchards, and silk manufactured therefrom; or any other agricultural or horticultural productions or household manufactures, which in their view shall by such encouragement add to the productive wealth of the country, not exceeding, however, in amount, the sum of five thousand dollars hereby placed in their hands.

§ 16. The collectors of taxes in the several towns in the state of New-York are hereby required, while collecting, the same, to ascertain, as near as may be in their power, the number of bushels of grain of different kinds, of esculent roots, and of hay produced during the current year in their respective towns, and the number of horses, cattle, sheep and swine then in existence, and report such amount to the board of agriculture in the city of Albany, on or before the first day of January in each and every year hereafter. Such report to be directed to "The State Board of Agriculture, Albany."

§ 17. The sum of twenty-five thousand dollars appropriated by this act, shall be taken from the income of the surplus fund deposited with the state of New-York by the United States.

§ 18. The first board of agriculture shall consist of
who are hereby appointed for the term of five years aforesaid, and all vacancies that may occur in said board shall be filled by joint ballot of both houses of the legislature at their annual session, to be held by the incumbents for the same period of time.

§ 19. The State board of agriculture shall procure of the agricultural periodicals entitled "The Cultivator," and "The Monthly Genesee Farmer," as many copies of each, commencing with the current volumes, as there are common school districts in the state, and shall cause ss many copies of each to be addressed to the school commissioners of each town as there shall be school districts in the same; and it shall be the duty of such school commissioners to cause the said papers to be promptly distributed, one copy of each to the several schools, and of the trustees of said school districts to have the same properly taken care of, and to be used as occasional class books in said schools.

§ 20. The comptroller shall, on the requisition of the said board of agriculture, draw his warrant on the treasury of the state for the payment to each of the proprietors of the said agricultural papers for the number of copies so delivered, estimating each of them at fifty cents per copy; such payment to be made from the common school fund.

EXTRACTS.

Agricultural Convention.

At a meeting of the citizens of the county of Onondaga, convened pursuant to public notice at the Mansion House, in Syracuse, for the purpose of adopting measures for the incorporation of a County Agricultural Society, ASA EASTWOOD, Esq., was temporarily called to the Chair, and MILES W. BENNETT, Esq. appointed Secretary. Whereupon it was

Resolved, That a committee of five persons be appointed by the Chair to report officers for the Convention.—The following persons were thereupon appointed said committee, viz: *Harvey Baldwin*, *James L. Voorhees*, ——— *Doane*, *H. Moses*, and *Rufus Cossit*.

The committee reported the following gentlemen as Officers of the Convention, viz: JAMES L. VOORHEES, President; GABRIEL TAPPAN, and ASA EASTWOOD, Vice-Presidents; *John B. Brown*, and *H. N. Howe*, Secretaries.

The report of the committee being adopted by the Convention, it was thereupon, on motion of Mr. *H. Baldwin*,

Resolved, That a committee of five be appointed by the President to draft resolutions expressive of the sense of this Convention on the subject of forming a Board of Agriculture for the county of Onondaga, and also to devise measures for procuring the incorporation of a County Agricultural Society,—whereupon, the President appointed the following gentlemen on said committee, viz: *H. Baldwin*, *B. F. Stone*, *E. F. Wallace*, *D. S. Earll*, and *R. Cossit*.

The committee, after a short recess, reported by their Chairman, *Mr. Baldwin*, the following resolutions, which were adopted by the Convention, together with the petition also reported by the committee.

Resolved, That we regard agriculture as the first and best pursuit of man, as a science more ancient in its origin, more useful in practice, and more important in its results to the whole human family, than any other art or science, and which therefore commends itself to the attention of every philanthropist and true patriot.

Resolved, That a science so intimately connected with the best interests of society, is entitled to our warmest approbation, and cordial, vigorous, individual, and united support, and that we will henceforth exert every means in our power to improve and elevate its character, disseminate its principles, and extend its blessings.

Resolved, That we regard as among the most efficient means for advancing these great objects, the establishment of State and County Agricultural Societies—the establishment of Agricultural Schools, in conjunction with pattern or experimental farms, and the periodical publication of Agricultural Papers, and that to establish, foster, sustain and protect these, is an imperative duty which every well regulated government owes to itself and to its citizens, and should at all times be regarded as an object of primary and paramount importance.

Resolved, That in view of the immense interests involved in the science of rural economy, as connected with the natural, physical, moral, political and religious wants of man, we, with deep humiliation confess, as well in our individual as in our corporate capacity, that we have hitherto come far short of our duty as men, as citizens, as philanthropists, as patriots, and as christians, and now offer, as the best atonement we can make, a dedication of our time and means to the advancement of this work, so far as it is consistent with other duties and other obligations.

Resolved, That the policy hitherto pursued by this state in refusing to grant pecuniary aid from the surplus revenue, for the promotion of this great object, is, in our opinion, unwise, illiberal and unfair—*unwise*, because her wealth consists in the wealth of her citizens, and whatever promotes the one, increases the other in the same ratio—*illiberal*, because the appropriation of that money to this object, was but to return it to hands from which most of it was directly or indirectly drawn, and because if returned it would have been again reinvested in a manner most beneficial to the state and the country—*unfair*, because the aid was solicited by a class composing seven-eighths of the whole community, and which, as such, has never to any considerable extent partaken of the bounties of the government.

Resolved, That the warmest thanks of this Convention, of this state, and of this nation, are due to those few individuals who have long been toiling with unabated zeal and perseverance in the cause of Agriculture—who have freely devoted to it their time, talents and money, and whose able and well conducted periodical publications have done much, and indeed, have mainly contributed to awaken public interest and inquiry on this all important subject; and in the foremost ranks of whose works, we, with pride and pleasure, recognize '*The Genesee Farmer*,' and '*The Cultivator*.'

Resolved, That a committee be apppointed for the purpose of circulating a petition to the present Legislature for the incorporation of a County Agricultural Society, with a capital of $50,000, with power to increase it to $100,000, to be divided into shares of $20 each, and to be employed, or so much thereof as may be necessary, in the purchase of an experimental farm—preparing and stocking the same, and in the establishment, in conjunction therewith, of an Agricultural School, and in such other objects as are calculated to advance the great and permanent interests of the institution.

Resolved, That Victory Birdseye, Azariah Smith, Phares Gould, James R. Lawrence, Samuel L. Edwards, Harvey Baldwin, James L. Voorhees, John Stevens and George Geddes be appointed delegates to represent this county in the next meeting of the State Agricultural Society, to be held in Albany on the first day of February next.

Resolved, That the proceedings of this Convention be signed by the officers thereof, and published in the county and village papers, the Albany Argus, Evening Journal, Gazette and Daily Advertiser, the Cultivator and Genesee Farmer.

To the Honorable the Legislature of the State of New-York, in Senate and Assembly convened:

Your memorialists, inhabitants of the county of Onondaga, beg leave respectfully to represent,

That from the benefits resulting to the farming interests in this county, from the law of 1819, establishing Agricultural Societies, your memorialists are satisfied that all the interests pertaining to rural economy would be largely promoted by the re-enactment of that law, or of some similar law on that subject.

Your memorialists are also satisfied that the cultivation of an experimental farm, and the establishment in connection therewith of an Agricultural School, would also have an important bearing on the same interests, and should be provided for, and protected by the future enactments of the State in relation to that subject.

Your memorialists, therefore, respectfully solicit your Honorable body to pass a general law for the incorporation of County Agricultural Societies, securing the aforesaid objects, or a law for the incorporation of an Agricultural Society of this County, incorporating therein provisions on the above subjects, with a capital of fifty thousand dollars, to be divided into shares of twenty dollars each, and for such other and further enactments and aid in reference to the subject matter, as to your Honorable body shall seem right and proper—all of which is respectfully submitted.

Syracuse, January 29, 1838.

JAMES L. VOORHEES, *Pres't.*
GABRIEL TAPPEN, } *Vice-Pres'ts.*
ASA EASTWOOD, }
John C. Brown, } *Sec'rys.*
H. N. Howe, }

Massachusetts Agricultural Society.

We have great pleasure in announcing some of the Premiums of the Massachusetts Agricultural Society. The society offered two most liberal premiums for the best and second best managed farm, which might be offered, requiring that the entry of these farms for premium should be made early in October, and that a full account of the whole condition and management should be given in detail. The first premium was 150 dollars, the second 100 dollars. It was hoped that these would have presented a sufficient inducement for many applications. The offer of premiums made by the society, though the trustees took great pains in extending it, did not reach all parts of the State; and in this matter it is to be feared great neglect is to be attributed to some persons in whose hands their prospectus was placed, and by which neglect the liberal and excellent intentions of the society have been in a measure defeated. The conditions were as liberal as they could with any propriety be made; and we have many farms in the state, which might have honorably entered into the competition. Only three claimants appeared, and two of those not having been seasonably entered, the trustees did not consider themselves at liberty to bestow on them either of the premiums; but bestowed liberal gratuities only. The claim seasonably entered was, for reasons detailed in their report, not deemed entitled to either of the premiums; but at the same time deserving of an honorable notice. We shall give the reports in full in our next paper, at this time we announce only the rewards.

To Joshua R. Lawton, of Great Barrington, in Berkshire Co., a gratuity of seventy-five dollars, ...	$75 00
To Joseph Howe, of Methuen, in the county of Essex, a gratuity of fifty dollars, ...	$50 00
To William Buckminster, of Framingham, in the county of Middlesex, a gratuity of fifty dollars,	$50 00

The statements of these several claimants, with their particular accounts of their management and crops will be given, in due season with the report. We presume that these premiums on the management of farms will be continued, and we hope they will excite that attention among our farmers, which they deserve. If the pecuniary value of these rewards is not sufficient to rouse them, yet have they no public spirit? have they no interest in the improvement of that great art, to which they have devoted their lives? and what can more directly contribute to its advancement than an animated and public competition? When we come to present the detailed reports to the public, we shall take occasion to extend our remarks. We have only to add that Mr. Howe, of Methuen, Essex Co., who appears here honored by a liberal gratuity, obtained a premium on his farm, of thirty dollars, from the Essex agricultural society, the current year. This returning home with two medals will, we hope, make his neighbors sufficiently envious to induce them to go and do likewise. If they choose to say, as we know they will say, there is nothing in Mr. Howe's farming which any body cannot do, we only say then in reply, let any body do it. That is the very thing we desire.

We subjoin the report of the committee on vegetable and grain crops.

The committee of the trustees of the Massachusetts agricultural society, on vegetable and grain crops, respectfully submit the following report.

Premiums they recommend as follows—

To Eldad Post, of Lenox, for the largest quantity of Spring Wheat, being 40 bushels to the acre, ...	$20 00
To Maxwell Lowry, of Marshfield, for his crop of carrots on an acre, being the only claim for that article, 472 32-56 bushels, ...	$30 00
To S. D. Colt, and Robert Colt, of Pittsfield, for the greatest quantity of vegetables for home consumption and not for sale, ...	$30 00
Also for the greatest quantity of Ruta Baga, being 1,080 bushels on 1 acre and 2 rods, ...	$30 00

The following claim was sent in too late to be admitted according to an indispensable rule of the trustees, but as the crop was uncommonly good, the committee recommend half the amount of the premium as a gratuity.

To Peleg S. Gardner, of Somerset, for his crop of Rye, on one acre, being 35 1-2 bushels, ...	$10 00

The committee notice with pleasure the following claims which, though not entitled to premiums deserve to be mentioned, as evidence of the increasing attention of our agriculturists to the raising of wheat, and as showing the practicability of growing to advantage this essential article of bread stuff, in Massachusetts.

Payson Williams, of Fitchburg, had to the acre of wheat, ...	38 1-2	bush.
Jos. S. Leland, of Sherburne, ...	32 14-32	"
Frederick Knight, of Newbury, ...	32 14-32	"

All these were Spring Wheat.

Mr. Benj. Cleveland, of Somerset, had 79 1-2 bushels of oats. No premium was offered on oats.

Mr. Peleg S. Gardner, had 40 1-2 bushels of barley on one acre. The quantity required was 45 bushels.

(Signed,) P. C. BROOKS,
Chairman.

The crops of wheat rewarded and noticed are excellent. Samples of some of them have been sent here; and present a beautiful grain. These are most important results, in various points of view. It is desirable that we should understand our capacity of raising our own bread. For some years past we have been rather too much engaged in making pictures, beautiful engravings on silk paper; and have been as much pleased with them as if we were all children. It would be well, if a large part of our population would go to producing something else, apply their ingenuity and industry to something more substantial, and see if they cannot induce the earth to make liberal dividends upon fair investments of manure and labor. The above results show what she can be made, or to speak more gratefully, what she is willing to do; or rather what she can be persuaded to do; and where shall we find any better investment than that which returns sometimes thirty, sometimes sixty, often a hundred fold for one.

The crops from Somerset are the effects of liberal manuring with fish. The effects of this manure, which is well known on many of the maritime parts of our state, are very powerful. But the farmers complain that is soon over; so is every thing else in human life soon over. I think, said a person to President Daggett of Yale College, on his introduction to him, you are President *pro tempore*—yes said he with some tartness of reply, would you have me President pro *eternitate?*—Every thing with us is for a *time*. Use it for that time and be thankful that it does well; but do not complain that its effects do not last forever. They were not meant to last forever. The pretence, that it impoverishes the land, is idle; and amounts to this, that the land will not produce so much without the manure as it did with it. The complaints of its being so transient, when its liberal returns are admitted whenever it is applied, are the complaints of selfishness and indolence.

The crop of carrots upon which a premium has been awarded is only an ordinary one; and we think the Board must have stretched their liberality as wide as the mantle of christian charity to have honored it as they have done. We presume however that they were bound by their rules, this being the only claimant. At any rate, we have no doubt they judged uprightly and well. It will, or it ought to make some men ashamed of their own neglect. We know several who have raised their six hundred, and eight hundred bushels of carrots to the acre, and we know some who have grown a thousand, who will say on reading this award, "Well I might have got that premium, if I had tried." Why did you not try then? Try next time, and try until you do get it; and then keep a trying, until you get it for a larger crop than was ever raised before. This is what farmers ought to do; and not be laying down in despair at the foot of every small hill, which they come to, which are often not higher than a tall man can look over, and crying out in despair, ah! I never can get over. Move on, Mr. Faintheart! Wake up, wake up! you sluggard!

Mr. Payson Williams, of Fitchburg, one of the most successful farmers in Massachusetts, who knocks every year at the door of the Massachusetts society, and whom they are obliged to admit because he shows his sufficient warrant to come in and take the best they have, has we believe been formerly honored with a premium for raising 55 bushels of Black Sea wheat on an acre. We have known in Massachusetts two hundred bushels of wheat gathered from four acres; and seventy bushels of rye grown on an acre; and ninety bushels of oats. What may not industry and skill effect. Barley is a crop, which ought to be much more cultivated than it is. The insect, which for some time, made fatal depredations upon it, has disappeared in a great measure. It was brought to this country in some importations of barley from Holland, made some years since by a large brewer in Newburyport.—The farmers for two or three years in that vicinity gave up the cultivation of barley, as they were advised and indeed obliged to do, and it became extinct. It ordinarily, to good cultivation, yields well. It does not mind a cold season, and for fatting swine, when intermixed with other feed, it is probably as good, pound for pound, as any other grain.

Caleb Kirk on Hedging.

Having preferred plashing to any other mode that I had seen made use of in training a hedge, I began the process when the stalks were about an inch in diameter near the root, and from that to an inch and a half; if well attended to in their previous growth, they will attain that size in six or seven years after they are planted, but if neglected they may require double that period. It may be observed that no advantage is gained by plashing before a good *root* is formed, for that is the future support and basis of the superstructure; by having a good strong root, the cutting or wounding the top or body of the stalk will soon recover any injury received in the necessary work of plashing, which is done by cutting the body of each stalk with a hedge knife or pruning hook, bending the stalk with one hand, in the direction it is to be laid, at same time by a stroke of the knife by the other, about four inches from the surface of the ground; if one stroke should not prove sufficient, a second or third may be applied, being careful to leave as much of the wood uncut as to afford the sap to flow into the top, and yet to bend easy into an inclined position of about forty-five degrees elevation from the base or bank on which it stands; one-third or one-fourth of uncut wood is sufficient to supply sap to the plashing, which must bend easy, otherwise it would incline to rise out of the proper degree of inclination. Much depends on this circumstance in forming a good and uniform hedge—the plashings should not press one upon another so much as to prevent a free and unobstructed circulation of air and the sun's rays also, as the health and vigor of the plashing is much promoted thereby. If there should be more wood in the hedge, by planting too close or any other cause, it must be cut away, leaving no more than what is really necessary to form the basis of a good and lasting live fence. One of my errors was, suffering too much brush wood to be crowded into my first live hedges, both living and dead—brush wood, such as was cut away, in some places where too thick, and filled in where too thin; in order to make a *present* fence I was induced to suffer it done in this way, from the recommendation of my hedger, who was from the west of England, and had been in that practice; for the immediate making a fence of such materials as he had to do with, I readily gave *his* judgment the preference, he having had experience in the business.

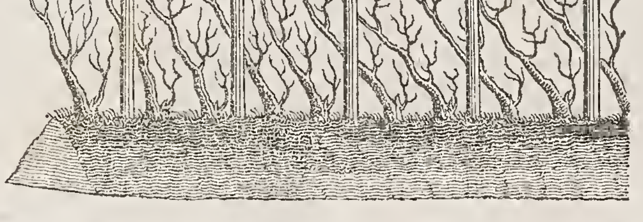
But my observations in two or three years more, convinced me of the impropriety of introducing dead wood to fill every vacancy, as well as crowding too much of that which was living. I had much of it to remove in places where a want of health demonstrated the present evil. After this was done, the remaining part became more healthy, but remains thin, and never will overcome the injury. There seems to be no inclination to put out shoots from the old wood in those vacancies—which would have put forth shoots when newly laid, if no obstruction had been present.

I find it is best to trim off the branches, especially the large ones, though not very close to the body of the stalk. It shoots young sprouts more abundantly from the plashing, which rise in an upright form, as well as those from the stumps shooting up through the plashing; interlocks the whole together, holding the plashing in their place as cross bars, and forms a kind of lattice work. On the contrary, if the plashing is too crowded, the shoots rising from the stump will evade the thicket and push out in a lateral direction, endeavoring to gain the benefit of sun and air, and rise on the outside, where they are injurious instead of beneficial; by secluding the plashing from the benefit of sun and air, the sap no longer inclines to the plashing, but flows freely into the suckers on the outside.

I have been more particular on this point, having seen errors in others, as well as my own, on that head.

Previous to laying a hedge, a quantity of stakes are to be provided about four feet and a half long, if it stands on a bank, or a little longer if the ground is not elevated, and split as small as they will bear to drive about one foot in the ground; they are to be driven through the plashing occasionally, as the work progresses, in a straight line two feet and a half, or three feet distant from each other, as seen in figure 18; those stakes are driven through the plashing, so as to keep the part laid directly over the stumps, for reasons before given, (the shoots raising immediately through the plash;) these stakes are bound in their place by wattles or poles, prepared of alder or willow, or any thing that will not in future make useful timber, as their use is only temporary, until the hedge becomes set by growth.

Fig. 18.



This binding has the appearance of a twisted rope; if rightly done it steadies the head of the stakes, and keeps them in a direct line, and serves the purpose of holding straggling shoots, that may be directed under its confinement, and confines the top of the hedge, holding it steady for trimming until its own growth gives it stability.

The next year after being laid it should be examined, and any shoot that inclines to leave the right direction should be cut away, unless there is a vacant spot to receive it; then it ought to be introduced into such vacuum; by frequently trimming the superfluous branches off, the body becomes more dense and impenetrable.

About five years past, I adopted the summer trimming about the middle of June, and found it much easier to accomplish while the shoot was in a tender state, and have regularly done the trimming in that and the following month ever since, finding the labor much easier performed, and no bad effect on the hedges, though warned by some to the contrary, apprehending bad consequences to arise from cutting at that season.

The present season having been excessively dry and warm, yet I have not discovered the least injury—though they have held their foliage as well as usual.

My conclusion has been, that by cutting when the sap is in full flow, and taking away the small shoots that were carrying off a considerable portion for their support, that portion must diffuse and spread through the whole body of the hedge, and add strength to every remaining part.

The foregoing remarks will apply to either kind of thorn as it regards the treatment of them, but the Virginia kind has advantages, though not so rugged in appearance, as the Delaware—they are more uniform in their growth, and give that regularity and uniformity to the hedge. But what is very important, is their inclination to send out an abundance of shoots or suckers, when cut not only from the stump, but from the plash also; the latter is not the case in the Delaware thorn; they seldom afford shoots out of the plash; except where the top end is cut off, the suckers will rise.

To attain a regular distribution of shoots from the plashing, we must be mindful to give every stalk laid a proper degree of slope or inclined plane, as before observed; by that means they are likely to rise on the body of the plash; if too much elevated the sap flows to the head, and produces a cluster at that point; and if laid too much in a horizontal position, the sap is not encouraged to follow that direction, and will produce succors from the stump only, leaving the plash without sufficient nourishment to become useful, and must consequently decline.

It will be readily understood, that the more general we can direct the flow of sap through the whole body of the hedge, the strength and uniformity is thereby promoted, becoming healthy in all its parts. After that object is obtained, all that is necessary, is the keeping it in proper limits by trimming.

The drawing represented by figure 18, is a view of a section of newly plashed hedge, divested of foliage, after having formed the first shoots from the old stalks, making the first effort to fill the vacancies, and seven years old before it was cut. The figure 19, represents a section of one that has been laid seven years, and annually trimmed, being in full foliage at the time the drawing was taken. The former showing the skeleton of a hedge, that may be useful to demonstrate the subject in that stage of its progress to maturity. Figure 20, represent an end view of section 19, showing a correct view of the shape, which I preferred for the forming a hedge the most impenetrable at the bottom; those views are elevated on a bank from a foot to eighteen inches high, which was formed from repeated dressing, as they required fresh earth to cover the grass about the roots, which retards their growth in a young state remarkably, if not kept down. This elevation gives the hedge a much more forbidden appearance to ungovernable animals.

Fig. 19.

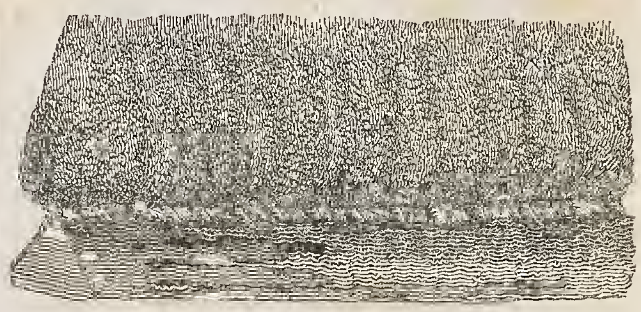


Fig. 20.

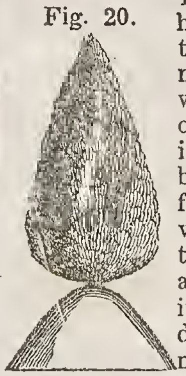

The trimming may be done with a hedge knife, about eighteen inches long, with a hooked point, used with one hand, or with any other sharp light tool that may best suit the operator, making the stroke upwards rather than downwards; the root being secure in the ground it will not give way before the stroke, as it would in making the stroke downwards. The last trimmings made on those specimens, were done with a common grass scythe, as the mowers were cutting the grass inclosed in the field. I found by applying the scythe to the hedge it was an expeditious mode, though rather unhandy to strike upwards, but a little practice overcame the difficulty.

After viewing those specimens of hedges produced by the foregoing mode of management and in a given time, it will be information to some, I have no doubt, sufficient to determine their choice, whether a dead or living fence is to be preferred.

I made the choice upon an imaginary view, without having advantage of ocular demonstration, and without any idea of the comparative expense, or even attempting to make any calculation on the subject, as I had made up my determination prefering a live fence.

There is now some data to form an estimate upon; and the subject is of such a nature as to require a series of years to gain the desired object; yet I have a confidence in believing it can be ascertained with much correctness.

The last number on this subject being more fully demonstrated by a drawing, not only to assist the young husbandman in the best mode of forming his live fences, but to give a view, of what may be considered a specimen of a *finished hedge*, or one that has attained maturity, being thirteen years old from the time of planting, and needs no further care but that of *annual* trimmings, shearing or clipping the extra shoots, that incline to enlarge it beyond proper limits. The mode has been heretofore treated of.

It now becomes the next inquiry *what is the cost* of obtaining such a desirable inclosure, to protect and secure the labors of the farmer, and, at the same time, ornament his farm. The following is a correct estimate, as near as the nature of the case will admit, calculated for the latitude or neighborhood of the writer of these notes, being done from actual experiments, made by himself, and some of his neighboring farmers pursuing the same plan of hedging; taking a given quantity or distance, say one hundred pannels of post and rail fence, measuring ten feet to the pannel, which is the usual length, makes *sixty perches* and ten feet over.

One thousand quicks will plant that distance, cost from nursery,		$5 00
Planting them by a man and boy each two days, man's wages and board at 75 cts.		1 50
boy's do. 50 cts.		1 00
One dressing the first year by running a furrow or two with the plough,		25
And then a light dressing with the hoe, (same hand)		75
Expense of first year,		8 50
2d. year dressing as above,	$1 00	
3d. year do.	1 00	
4th. year do.	1 00	
5th. year do.	1 00	
6th. year do.	1 00	
5 years dressing,	——	$5 00
7th. year trenching to prepare for plashing, plough and horse,	$0 50	
And three days' work, at 75 cts. throwing up a ditch,	2 25	
500 stakes, counting labor as above, including timber,	3 50	
Wattles and cutting them,	2 00	
One hand three days at plashing, at $1*	3 00	
Expense of 7th year,	——	11 25

---

* The wages of a hand to plash is at $1, being an artist at the business, but that will, when generally in practice, be done by common laborers as readily as any other labor on a farm, with a little attention of the owner.

8th. year 1 day's work trimming and cleaning,	$0 75	
9th. do. do.	75	
10th. do. do.	75	
11th. do. do.	75	
12th. do. do.	75	
13th. do. do.	75	
Expense of six years,		$4 50
		$29 25

The foregoing process has produced such a hedge as is exhibited in the drawing, taken from a section of one thirteen years old, now in good condition and improving, becoming more dense every year; and, so far as I am able to form a judgment, I am of the opinion, that seventy-five cents annually applied to the trimming, will keep it in that form perpetually, not being yet able to discover any thing to form an idea of dissolution upon, in any reasonable time, therefore sufficient to ground a confidence of durability.

The calculation on this section of sixty perches, will afford data to apply to any quantity of greater extention; and the annual expense on this, after the seventh year, is uniform, and may be considered to continue so, for as long a time as they are regularly attended to, which will apply to any extent, at one cent and a quarter per rod or perch of sixteen and a half feet.

If the writer of those observations had commenced hedging with the knowledge now obtained by experience, one-half his labor would have been saved.

The expense of a fence made of timber, say post and rail, which is the most common in the vicinity of this place, is seventy-five cents for each pannel of a four rail fence, to those who have their fencing to purchase and the labor to pay; that is, seventy-five dollars for one hundred pannels, that, compared with the same length of hedging, places the case, for a perishable material, with thirteen

years of the time gone,	$75 00
And for a hedge growing better every year,	29 50
Leaving,	$45 50

as a balance in favor of sixty perches and ten feet distance; what that will amount to on a large farm, I shall leave to the owner's calculation.

I may further remark, the labor of making live fence can be done by weak hands, if rightly directed; my plashing was done by a man seventy-four years of age. The making of rails and handling them requires a person in the prime of life, and it is laborious in every stage of the process of erecting wooden fences; besides the destruction of much valuable timber, which, in some neighborhoods, is a heavy tax on the owner.

Each neighborhood may make their calculations of fences made of timber; according to circumstances attending the hedge, calculation may be relied on, if the rules and remarks foregoing are strictly attended to, and will apply to either kind of thorn; but it was the "Virginia parsley leafed thorn," of Marshall's catalogue of forest trees, that was preferred, and which grows spontaneous, from this place to the south as far as the Mississippi; and I have no doubt of it thriving in a northern latitude, seeing no bad effect from the winters of our Delaware climate, although I had a section plashed in the midst of winter to prove the consequence.

The hedge may be considered as made in seven years from time of planting, as it is only trimming, that is required afterwards; which amounts to one cent and a quarter for each perch of distance; the quarter may be thrown off, if the clipping is never *omitted in due time*, as it lessens the labor; a rule that will apply through every operation in husbandry, and should *never* be forgot, while twenty-five per cent is saved, often fifty.

Broad-tailed Sheep.

[*From Livingston's Treatise on Sheep.*]

"The race of sheep that I shall next notice, is one that is *more extensively diffused than any other*, since it is found throughout Asia and a great part of Africa, as well as through the north-eastern parts of Europe. I refer to the *broad-tailed sheep. (Ovis aries lati-caudata).* These differ as the ordinary European race in the nature of their covering. In Madagascar, and some other hot climates, they are *hairy*, at the Cape of Good-Hope they are covered with coarse harsh wool; in the Levant their wool is extremely fine, or in other words, they are *adapted to the necessities of the people* by whom they have *been changed from their wild to their domestic state.* These sheep *are generally larger than those of Europe*, in which circumstance only, and the form and size of their tails, they differ from them. The broad-tailed sheep are of three species. In the one the tail is not only broad, but long, and so weighty, that the shepherds are compelled to place two little wheels under it, to enable the sheep to drag it. These tails are said sometimes to weigh from forty to fifty pounds. Another species have the tail broad and flat, but not very long, covered with wool above, but smooth below, and divided by a furrow into two lobes of flesh; these are also said to weigh above thirty pounds: I should not however estimate the weight of those which I saw in the Menagerie at Paris, at more than ten or twelve pounds. *In some species a small thin tail projects from the centre of this fleshy excrescence.* The composition of this excrescence is said to be a mixture of flesh *with a great proportion* of *fat*, and to be a very delicate food; *but the animal has little other fat, the tail being in him the repository of that fat which lays about the loins of other sheep.* In cold climates the fat of the tails *resembles* suet; but in warm ones, as at the Cape of Good Hope, Madagascar &c. it is *so soft that when melted it will not harden again.* The inhabitants *mix it with tallow* in certain proportions, when it *assumes the consistency of hog's lard*, and is then eaten like butter, or used for culinary purposes. *Naturalists* imagine that this excresence is owing to some circumstances in the food of the sheep, which makes the *fat fall down from the loin into the tail* and thus occasion this *monstrosity.* I do not, however, think this probable, since the *prodigious extent of country through which this race is propagated*, must render the food as various as the climates in which they are bred. I rather think *it owes its origin to the art of man*, grounded on some of *those sports of nature*, which in all domestic animals, afford a basis whereon to *engraft his whims.*

It may be asked to what end would man cultivate this *deformity*, and that, too, through so extensive a region as to forbid our attributing it to whim or fashion? may not *the shepherd who first observed this Lusus Naturæ* in his flock have concluded, that he had made a very valuable acquisition, since he not only had a sheep that gave him *as much wool, milk or flesh* as the rest of his flock, but *a tail*, which, *in addition*, gave him a comfortable meal, or *what is still more valuable among savages*, plenty of *grease for his toilet and his kitchen.* This circumstance alone would make him attentive to *cherish and propagate the deformity;* and the rather as he must soon have found that it was attended with another important advantage; the sheep being *more unwieldly*, would be less apt to stray or return to its savage state; an object of considerable importance in the early state of society."

Rohan Potato.

[*From the Gardner's Journal.*]

We have had occasion to mention this potato in a manner to draw public curiosity strongly towards it. We subjoin, therefore, the account given of it in the Edinburgh Quarterly Journal of Agriculture. Some of these potatoes have been raised by Mr. Thompson, of Catskill, and by Judge Buel, of Albany, who received some tubers through the kindness of Mr. Thompson. The circumstances under which they have been cultivated here, were not altogether favorable; and the yield not so great as represented in the Journal from which we quote, but sufficiently remarkable to indulge sanguine expectations of their extraordinary productiveness. Their value for eating has not been ascertained. Their value for stock is undoubted. The Agricultural Commissioner was able, through the politeness of Judge Buel, to obtain a few plants; and others by purchase, which he will take care to distribute among those who will give them a fair trial. We learn that Messrs. Breck & Co. have the promise of a small quantity for sale, from Catskill, which may be expected as soon as the season will admit of their transportation.

The Rohan Potato, a new variety.—The following is an extract from a letter written from Geneva, of date 25th April, 1834, by Prince Charles de Rohan to M. Jacquemot-Bonnefont, Nurseryman, Annoney, in the Ardeche.

"I send you, through my friend M. Romilly, the potato which I promised you; and to which my name has been given in this country. The history of this potato is not less singular than the potato itself. He who obtained it from seed four years ago shews it, but will not give it to any person; he has refused it to King William. He has cultivated it in a little walled inclosure: he only wishes to see it in perfection, and the seed of the following year. He makes them to be taken up in his presence; keeps them under lock and key, and to be cooked for himself and cattle before his face. It is at great risk that I have been able to procure two tubers. This exclusive amateur having learnt that I had got some *cactuses*, which he wished much to have, begged me to give him some. I wished no money, but very much to have some of his wonderful potato. He gave me two of them, and made me give my word of honor that I would never send any of them to Holland, Belgium, England, Prussia, or Germany. Happily he has not thought of Switzerland nor France; for without this omission, I could not have had the pleasure of offering these to you.

"This is the mode of cultivating this potato: The earth is dug to the depth of twenty inches; make the distance between the holes four feet, and put two or three eyes, or sets, in each hole. Earth up frequently. The stalks, reaching six or seven feet in height, must be supported on transverse stakes. The kind being late, the tubers, which are very farinaceous, should only be taken up about Martinmas, when the stalks wither.

"To give you an idea of the extraordinary produce of this potato, I give three examples at random. M. E. Martail, at Alias, gathered last autumn tubers weighing 13 lbs. 7 oz., 11 lbs. 9 oz., and 9 lbs. 13 oz. M. de Montet, a proprietor near me, asked me for tubers when I could not give him more than a single small tuber having four eyes He weighed it for curiosity, and found that it wanted a few grains to make half an ounce. However, this small tuber being planted, produced 48 1-4 lbs. The Attorney of the Abbey of Auterive, canton of Fribourg, to whom I had given two tubers two years ago, and who, delighted with his first harvest, after having eaten and given some to his friends, planted the rest, and obtained last autumn six double-horse loads and eight scuttle-fulls. It is not the largest tubers which succeed best as seed."—*Le Cultivateur, Journal des Progres Agricoles.*

Orchard Grass;

Its value, and advantages over Timothy or Clover. Remarks on its culture, and seed. Poa viridis, or Green Grass.

Sow Orchard Grass; if in autumn, harrow it in with your winter grain. Some prefer sowing it in the spring. Much depends on the soil and season, and you can try both modes and periods, to enable you to form the best opinion. This grass will be permanent, when *clover* (with which it is a profitable companion,) fails. It is, on uplands, preferable to *timothy*, which is a great exhauster—yields but one crop of hay, and little or no pasture, on dry soils, thus leaving the field bare of cover, and exposing it to the exhaustion of the sun and winds; whilst orchard grass, by its quick and repeated growths, affords a ceaseless cover and defence.

By thus recommending *Dactylis glomerata*, for permanent pasture and hay, it is not intended to cast the least reflection on the clover culture. This is now so commonly practised, and its uses so generally acknowledged, that it is unnecessary to dwell on its excellent properties. But the clover is fugacious, (short lived,) and the orchard grass, sown with it, endures in uninterrrupted vigor and usefulness; when clover, in dry seasons particularly, is burned or shrivelled, or has entirely departed, having lived out its short period of existence; or having been prematurely destroyed by frosts, to which it is often a victim. The *clover* and *plaster* are so congenial, and the improvement of the soils suitable for them so universally known, that any detailed notices of them would now be superfluous.

Raise your orchard grass seed, and do not spare it on your fields. Thin sowing throws up tufts, detached and coarse. You buy, in the shops, much chaff, and little seed; insomuch that a bushel weighs only from fourteen to sixteen pounds, at best, and some much less, barely sufficient for an acre. It should be sold by weight, and not by measure. No grass seed can be raised more plentifully and cheaply; and yet the expense of purchasing, has deterred its more general use.

It will be difficult to keep an old weedy farm long in grass; and the plough must, therefore, be oftener used than a clean farm requires. Yet with composts, as top-dressings, and destruction of weeds, wonders may be performed in a *grazing* system. But when the old sod is broken up, *time*, as well as good husbandry, with proper courses of crops, must be afforded. No winter grain should be sown the first season of breaking up old grass lays. The stirring and culture of that and the ensuing year, are necessary to insure the complete destruction of weeds and other unprofitable vegetation.

If you should be so fortunate as to conquer weeds and pests, and obtain a clean cover of the *poa viridis*, or green grass, which will not grow unmixed in all soils; it is not to be told how long your fields, with top-dressings, will continue without being disturbed by the plough, if scarified, when surface-bound, by a proper instrument. This grass appears to be native, though not peculiar, to this country; and it must, according to general experience, grow spontaneously.

Plants spring up in soils in which they are indigenous, without previous seeding. The experiment of cleaning by tilling, and meliorating by manure, worn out lands, and suffering them to throw up grasses spontaneously, has decisively succeeded, so as to insure valuable crops of the appropriate kinds; which finally established themselves, after contending with intruders for a time. *White clover* seems most universally native; but *this* grows better in some, than in other soils.

Those who do not attend to the laws of nature in this regard, suppose that they can, *with plenty of manure*, force plants in any soil; but this is a great mistake. *Gorging* land with dung, for any product, is expensively ruinous. There is no surer mode of first deteriorating and finally destroying, any plant out of its natural soil, than that of lavishingly dunging it. And this misapplied extravagance, is injurious to plants, either of rich or poor soils. The latter are, however, the soonest killed by high dunging.—*Judge Peters.*

Agricultural Chemistry.

[*From the American Farmer.*]

The great Linnæus, has almost given animal life to vegetables, by his wonderful system of classification, and the eccentric Darwin, would fain give them passions like human nature; but it has been reserved for modern chemistry to discover, that vegetables possess a most refined taste, a wonderful discrimination in the selection, and the most active chemical powers in the preparation of their food. It is in vain to search for any single article as the "food of plants;" their tastes are as various as the taste of man; they invariably seek for those things which they like best; and if they cannot find them, they will take what they can get. Indian Corn in the vegetable kingdom, is like swine in the animal; it feeds indiscriminately and voraciously on all the food it can procure, and its growth and product is in proportion; while the more delicate mint is satisfied with water alone, from which it extracts its small portion of food. The seed of a vegetable may be considered the magazine or granary in which is contained the germ of the future plant, and a requisite supply of food to support it. In establishing itself in the earth, the germ in many *comparatively large seeds*, is so small, as to escape the power of the naked eye. What then is the vision of man, when compared with that power which creates in an *invisible seed*, an embryo plant, perfect in all its parts, perhaps an hundred times smaller than the seed itself? The grain preserves and defends the germ from injury until placed in its proper sphere of action. The earth then furnishes food to it, by its power of absorption, which it natually exacts as soon as it comes in contact with moisture. When it has taken in a sufficient quantity of water, the germ commences its operations by decomposing a part and appropriating to itself the oxygen, it gains strength and bursts its cell—it now finds itself in presence of earth and air.* It puts forth its fibrous roots in quest of more substantial food among the mineral and saline solutions in the earth, and separates, with unerring fidelity, those which are required for the formation of the plant. In the mean time its head rises towards the heavens, and bursts the surface of the earth; the voluntary expansion of its leaves, seems to offer praise to its Creator; the sun stamps upon it his brilliant colors, and gives the flower its beauty; by its heat, the plant prepares its oils, gums and balsams; and in return, gives to the light its oxygen, (which, for aught we know, may be the support of the sun.) The winds agitate the plant, and often threaten to carry away the beautiful superstructure; while its motions indicate to the root below, that it is in danger. The elder roots grasp with firmer strength the earth, and send forth an increased number of fibres, which collect materials and increase the growth of the plant. These operations go on until the fruit is produced, when the plant resigns itself to indolence, and delivers to the hand of man the result of its labors. Some are permitted to resume their action after delivering to the earth their fruit and leaves; but the greater number sink to the earth and furnish subsistence for the growth of some future plants. This is the unvaried round of matter, it lives, and dies to fill some other life.

---

* It is usual to confine the presence of the air to the earth, but tillage extends it beneath the surface from one to twelve

Good yield of Corn.

[*From the Genesee Farmer.*]

Mr. Tucker.—The subscriber has raised 292 bushels of ears of corn from two acres, or 73 bushels of sound shelled corn per acre, of the Dutton corn, which I obtained from Judge Buel, Albany, a year ago last May. Process of tillage as follows: The land was gravelly loam, clover sod, mowed three years previous; ploughed once in April, rolled lengthways of the furrows and dragged the same way; planted the 4th day of May, three feet each way, with four spears in the hill; the seed rolled in plaster; ploughed and hoed three times, the ordinary way; plastered twice, one bushel to the acre, after the first and second hoeing. Cut up and stooked the 15th of September. It was ripe enough to cut up the 1st of September. I harvested it the last of October. If you think the above worthy a place in your paper, it is at your service.

N. B. One ear of the corn had twenty rows on it; sixteen had fifty-five kernels each, which made 880; the other four had twenty-seven each, which made 108; total, 988 kernels. Beat that! D. SUNDERLIN.

Yates county, Dec. 1837.

Young Men's Department.

Natural Philosophy.

VI. Electricity.—This name has been given to a science which explains and illustrates the operations of a very subtile fluid called the electric *fluid*, which appears to pervade every part of nature, and to be one of the chief agents employed in producing many of the phenomena of the material world. If a piece of amber, sealing wax, or sulphur, be rubbed with a piece of flannel, it will acquire the power of attracting small bits of paper, feathers, or other light substances. If a tube of glass, two or three feet in length, and an inch or two in diameter, be rubbed pretty hard, in a dark room, with a piece of dry woollen cloth, besides attracting light substances, it will emit flashes of fire, attended with a crackling noise. This luminous matter is called electricity, or the *electric fluid.* If a large globe or cylinder of glass, be turned rapidly round, and made to rub against a cushion, streams, and large sparks of bluish flame will be elicited, which will fly round the glass, attract light bodies, and produce a pungent sensation if the hand be held upon it. This glass, with all its requisite apparatus, is called an *electric machine.*—It is found, that this fluid will pass along some bodies, and not along others. The bodies over which it passes freely are water, and most other fluids, except oil, and the ærial fluids; iron, copper, lead, and in general all the metals, semi-metals, and metallic ores; which are, therefore, called *conductors* of electricity. But it will not pass over glass, rosin, wax, sulphur, silk, baked woods, or dry woollen substances; nor through air, except by force, *in sparks*, to short distances. These bodies, are, therefore, called *non-conductors.*

The following facts, among others, have been ascertained respecting this wonderful agent:—That all bodies with which we are acquainted, possess a greater or less share of this fluid—that the quantity usually belonging to any body produces no sensible effects; but when any surface becomes possessed of *more* or *less* than its natural share, it exhibits certain appearances, in the form of light, sound, attraction, or repulsion, which are ascribed to the power called *electric*—that there are two different species of the electric fluid, or, at least, two different modifications of the same general principle, termed *positive*, and *negative* electricity—that positive and negative electricity always accompany each other; for if a substance acquire the one, the body with which it is rubbed acquires the other—that it moves with amazing rapidity; having been transmitted through wire of several miles in length, without taking up any sensible space of time; and, therefore, it is not improbable, that were an insulated conducting substance extended from one continent to another, it might be made to fly to the remotest regions of the earth in a few seconds of time—that it has a power of suddenly contracting the muscles of animals, or of giving a *shock* to the animal frame—that this shock may be communicated, at the same instant, to a hundred persons, or to an indefinite number who form a circle, by joining their hands together—that it may be accumulated to such a degree as to kill the largest animals—that vivid sparks of this fluid, attended with a crackling noise, may be drawn from different parts of the human body, when the person is *insulated*, or stands upon a stool supported by glass feet—that electricity sets fire to gun-powder, spirits of wine, and other inflammable substances—that it melts iron wire, and destroys the polarity of the magnetic needle—that it augments the natural evaporation of fluids, promotes the vegetation of plants, and increases the insensible perspiration of animals; and can be drawn from the clouds by means of electric kites, and other elevated conductors.—By means of the electric power, small models of machinery have been set in action: orreries to represent the movements of the planets, have been put in motion; and small bells have been set a ringing for a length of time; and, in consequence of the knowledge we have acquired of the mode of its operation in the system of nature, the lightnings of heaven have been arrested in their course, and constrained to descend to the earth, without producing any injurious effects.

From these, and a variety of other facts and experiments, it is now fully ascertained, that *lightning* and electricity are identical; and that it is the prime agent in producing the awful phenomena of a thunder storm; the lightning being the rapid motion of vast masses of electric matter, and *thunder* the *noise*, with its echoes, produced by the rapid motion of the lightning through the atmosphere. There can be little doubt that, in combination with steam, the gases, and other agents, it also produces many of the terrific phenomena of earthquakes, volcanoes, whirlwinds, water spouts, and hurricanes, and the sublime corruscation of the *aurora borealis.* In the operations of this powerful fluid we behold a striking display of the sovereignty, and majestic agency of God. In directing its agencies, "his way is in the whirlwind and in the storm, and the clouds are the dust of his feet; the heavens are covered with sackcloth, the mountains quake before him, the hills melt, the earth is burned at his presence, the rocks are thrown down by him:" Neh. 1. 3—6. It is easy to conceive, that, by a few slight modifications produced by the hand of Omnipotence, this powerful fluid might become the agent of producing either the most awful and tremendous, or the most glorious and transporting scenes, over every region of our globe. As it now operates, it is calculated to inspire us rather with awe and terror than with admiration and joy; and to lead our thoughts to a consideration of the state of man as a depraved intelligence, and a rebel against his maker.

VII. Galvanism is intimately connected with electricity, though it is generally considered as a branch of chemistry. It is only another mode of exciting electrical action. In electricity the effects are produced chiefly by *mechanical* action; but the effects of Galvanism are produced by the *chemical* action of bodies upon each other. If we take a piece of zinc, and place it under the tongue, and lay a piece of silver, as big as a half crown, above it; by bringing the outer edges of these pieces in contact, we shall immediately experience a peculiar and disagreeable taste, like that of copper. The same thing may be noticed with a guinea and a piece of charcoal. If a person, in the dark, put a slip of tin foil upon one of his eyes, and a piece of silver in his mouth, by causing these pieces to communicate, a faint flash will appear before his eyes. If a living frog or a fish, having a slip of tin foil pasted upon its back, be placed upon a piece of zinc, by forming a communication between the zinc and tin foil, the spasms of the muscles are excited. These and similar effects are produced by that modification of electricity which has been termed *galvanising.* Three different conductors, or what is termed a *galvanic circle*, are requisite to produce such effects. A piece of copper, a piece of flannel, moistened with water or acid, and a piece of zinc, laid one upon another, forms a circle; and if this circle be repeated a number of times, a galvanic pile or battery may be formed capable of giving a powerful shock. The most common and convenient form, however, of a battery, is found to be a trough of baked wood, three or four inches deep, and as many wide. In the sides are grooves, opposite to each other, into each of which is placed a double metallic plate, of zinc and copper soldered together, and the cells are then either filled with salt and water, or with a solution of nitrous acid and water.

By means of the galvanic agency, a variety of surprising effects are produced. Gun-powder, cotton, and other inflammable substances, have been inflamed—charcoal has been made to burn with a most brilliant, and beautiful white flame—water has been decomposed in its elementary parts,—metals have been melted and set on fire, fragments of diamond, charcoal, and plumbago, have been dispersed, as if they had been evaporated—platina, the hardest and the heaviest of metals, has been melted as readily as wax in the flame of a candle—the sapphire, quartz, magnesia, lime, and the firmest compounds in nature, have been made to enter into fusion. Its effects on the animal system are no less surprising. When applied to a fowl or a rabit, immediately after life is extinct, it produces the most strange, and violent convulsions on the nervous and muscular system, as if the vital functions were again revived; and when applied to the human body after death, the stimulus has produced the most horrid contortions and grimaces in the muscles of the head and face; and the most rapid movements in the hands and feet.

The galvanic agency enables us to account for the following, among other facts:—Why porter has a different, and more pleasant taste, when drank out of a pewter vessel, than out of glass or earthen ware,—why a silver spoon is discolored, when used in eating eggs,—why the limbs of people under amputation, are sometimes convulsed by the application of the instruments,—why pure mercury is oxydised when amalgamated with tin,—why works of metal, which are soldered together, soon tarnish in the places where the metals are joined,—and why the copper sheathing of ships, when fastened with iron nails, are soon corroded about the place of contact. In all these cases a galvanic circle is formed, which produces the effects. We have reason to believe, that, in combination with the discoveries which modern chemistry is daily unfolding, the agency of the fluids will enable us to carry the arts forward towards perfection, and to trace the secret causes of some of the most sublime phenomena of nature.

VIII. Magnetism.—This department of philosophy describes the phenomena, and the properties of the *loadstone*, or natural magnet. The natural magnet is a hard dark colored mineral body, and is usually found in iron mines. The following are some of its characteristic properties:—1. It attracts iron, and steel, and all substances which contain iron in its metallic state. 2. If a magnet be suspended by a thread, or nearly poised on a pivot, or placed on a piece of wood, and set to float in a basin of water, one end will constantly point nearly towards the north pole of the earth, and the other toward the south; and, hence, these parts of the magnet have been called the *north* and *south poles.* 3. When the north pole of one magnet is presented to the south pole of another, they will attract each other; but if the north pole of one be presented to the north pole of another, or a south pole to a south, they will repel each other. 4. A magnet placed in such a manner as to be entirely at liberty, inclines one of the poles to the horizon, and of course elevates the other above it. This property is called the *dipping* of the magnet. 5. Magnets do not point directly north and south; but in different parts of the world with a different *declination* eastward or westward of the north; it is also different at the same places at different times. In London, and in most places of Great Britain, the magnetic needle, at present, points about 24 degrees to the west of north. For more than 160 years it has been gradually declining from the north to the west; but seems of late to have begun its declination to the eastward. 6. Any magnet may be made to communicate the properties now mentioned, to any piece of iron and steel. For example, by gently rubbing a penknife with a magnet, it will be immediately invested with the property of attracting needles, or small pieces of iron and steel. 7. Heat weakens the power of a magnet, and the gradual addition of weight, increases the magnetic power. 8. The properties of the magnet are not affected either by the presence or the absence of air; and the magnetic attraction is not in the least diminished by the interposition of any bodies except iron. A magnet will equally affect the needle of a pocket compass, when a thick board is placed between them as when it is removed. It has lately been discovered, that the *violet rays of the solar spectrum*, when condensed with a convex glass, and made to pass along a piece of steel, have the power of communicating to it the magnetic virtue.

The cause which produces these singular properties of the magnet, has hitherto remained a mystery; but the knowledge of the *polarity* of the magnet has been applied to a most important practical purpose. By means of it, man has now acquired the dominion of the ocean, and has learned to trace his course through the pathless deep to every region of the globe. There can be little doubt that magnetism has an intimate connexion with electricity, galvanism, light, heat, and chemical action; and the discoveries which have been made lately, and the experiments which are now making by Morichini, Oersted, Abraham, Hansteen, Barlow, Beaufoy, and Scoresby, promise to throw some light on this mysterious agent, and on the phenomena of nature with which it is connected.—*Dick.*

Abuse of Memory.

We recommend to teachers and others, who are in the habit of requiring children to commit long pieces to memory, the opinion of Lord Bacon upon this subject.

"The powers of the memory," he observes, "without the help of writing, can do little towards the advancement of any useful science." He acknowledges that the memory may be disciplined to such a point, as to be able to perform very extraordinary feats. But on such feats he sets little value. The habits of his mind, he tells us, are such that he is not disposed highly to rate any accomplishment, however rare, which is of no practical use to mankind. As to these prodigious achievements of the memory, he ranks them with the exhibitions of rope dancers and tumblers. "The two performances," he says, "are of much the same sort. The one is an abuse of the powers of the body; the other is an abuse of the powers of the mind. Both may perhaps excite our wonder, but neither is entitled to our respect."

We should often have reason to be ashamed of our most brilliant actions, if the world could see the motives from which they spring.—*Rochefoucault.*

We do not know what is really good or bad fortune.—*Rousseau.* Our condition in this world is mixed. We all, in *every state*, have our sufferings, but of none is the condition so abject, that he may not find grounds, of consolation, and discern the merciful finger of Omnipotence, pointing out to him a place of rest, of happiness unmixed, of everlasting peace.

We seldom find persons whom we acknowledge to be possessed of good sense, except those who agree with us in opinion.—*Roche't.* When such occasions do occur, our self-love always induces a decision in favor of their judgment.

☞ Mr. Allen has reported a bill in assembly proposing a bounty of ten cts. per pound for cocoons, and of fifty cts. per pound upon sewing silk, produced from family labor.

inches, hence the difference in the same earth, cultivated and uncultivated; the presence of the atmosphere being requisite for vegetation as soon as the germ bursts the seed.

THE CULTIVATOR:

A MONTHLY PUBLICATION, DEVOTED TO AGRICULTURE.

I KNOW OF NO PURSUIT IN WHICH MORE REAL AND IMPORTANT SERVICES CAN BE RENDERED TO ANY COUNTRY, THAN BY IMPROVING ITS AGRICULTURE.—*Wash.*

VOL. V. NO. 3, WASHINGTON-ST. ALBANY, N. Y. APRIL, 1838. NO. 2.

Conducted by J. BUEL, of Albany.

TERMS.—ONE DOLLAR per annum, to be paid in advance. Subscriptions to commence with a volume.

Special Agents.—L. & R. HILL, Richmond, Va.; BELL & ENTWISLE, Alexandria, D. C.; GIDEON B. SMITH, Baltimore, Md.; JUDAH DOBSON, bookseller, and D. LANDREITH, seedsman, Philadelphia; ISRAEL POST, booksellers, 88 Bowery, ALEX. SMITH, seedsman, P. WAKEMAN, office of the American Institute, Broadway, N. York; E. M. HOVEY, Merchants's Row, Boston; ALEX. WALSH, Lansingburgh, and WM. THORBURN, Albany, gratuitous agents. For general list of agents see No. 12, vol. iv.

The Cultivator is subject to common newspaper postage.

☞ Price of the published volumes, 50 cents per vol. stitched—the four volumes bound together, $2.75—bounded in two volumes, $3—the four vols. bound each separate, $3.25.

THE CULTIVATOR.

TO IMPROVE THE SOIL AND THE MIND.

The New Husbandry.

Having shown that manures are indispensable to good husbandry—that they constitute the food of plants—and that they may be greatly increased by good management, we proceed now to the second requisite in the new system of husbandry, viz:

II. DRAINING.

Few improvements of modern date are likely to become more beneficial to the northern section of the union, than systematic draining. In the first place it will reclaim, and render highly productive, large tracts of land, which are now unproductive in any thing useful, by reason of the water which constantly covers or saturates them. In the next place, it will improve lands that are wet, and render them far more manageable and productive, in grain, roots, and the more nutritious grasses, by carrying off the superfluous water. Where there is an excess of moisture in the soil, ploughing can only be imperfectly performed, nor until late in spring,—the benefit of manure is lost, and the cultivated crop is light, and more subject to vernal and autumnal frosts, than it would be if the land was laid dry.

The soil, in regard to vegetable nutrition, may be compared to the animal stomach, which digests,—and the spongeoles or rootlets of the plant to the lacteals of the animal, which absorb and take up, and propel, the digested food to the elaborating organs—the lungs of the one, and the leaves of the other,—where this food undergoes its last preparation, and is fitted to become a part of the organic matter of the animal or vegetable. We all know that when the animal stomach is out of order, from any cause, so that the food taken upon it is not properly digested, the subsequent processes of nutrition are arrested, and if the cause is not removed, the animal sickens, and ultimately dies. So with the soil. If the vegetable matter deposited there, to feed the crop, is not decomposed, or rotted, and resolved into a liquid or gaseous form, so that it can be taken up by the spongeoles, the plant will become sickly and unproductive, and the processes of healthy nutrition be at a stand. Hence the accumulation of vegetable matters in swamps, marshes and other locations habitually saturated with water, and their great fertility when thoroughly drained, and exposed to the influence of all the agents of putrefaction; and hence the necessity of draining the wet grounds on our farms before we can expect to make them profitable by culture. Coarse and aquatic plants, it is true, do grow in wet grounds, and in water; but few of the cultivated crops, however, are found to thrive where the ground is not dry and permeable to the influence of the sun and atmosphere.

It is not enough that the surface of a soil be dry: it must be so to the depth to which the roots of plants penetrate for food, at least fifteen to eighteen inches, to insure a healthy growth of vegetation. It is the extremities of these roots which gather the food, and which are constantly elongating while the plant grows; and if roots extend into a wet stratum, the food which they take up is either too much diluted, or not otherwise adapted to a healthy vegetation. Nor is this all: the water injures or destroys the fibrous parts of the roots, and unfits them for the performance of their functions.

We have published ample directions in the Cultivator, for the various modes of draining; and have pressed upon the notice of our readers the importance of this branch of improvement. Yet we have a few remarks to offer here, on the particular advantages which underdrains possess over open drains, in certain locations.

The object of draining being to carry off the surplus water before it saturates the surface soil, impedes early tillage, and injures the crop, it should be our first care to ascertain the cause of wetness, and where the deposite, or fountain is, which is the source of the evil. Where water rises through the subsoil or the lower strata, in spouts or springs, as well as where, falling upon a flat surface, it collects and reposes upon an impervious subsoil, underdrains are decidedly best, at least to collect the surplus waters into a main open drain. They are not only best, because the most efficient, but they are the most durable, most economical, and waste no land.

They are the most efficient. They can be made to reach, by digging and boring, the depot of water, or water stratum, and thus to carry it off before it approaches the surface, or pasture of plants. Open drains do this but seldom, or but imperfectly, because they are not often carried deep enough, and are continually liable to obstructions, which impair their efficacy.

They are most durable. An underdrain, laid in the most approved mode, with stone or tile, will last an age, if not a century. Open drains are but temporary in their beneficial effects, without periodical repairs.

They are the most economical. A good underdrain generally costs no more than a good open drain, which effects a like purpose, and probably not so much, as the former can be carried down with nearly perpendicular sides, while the latter must be dug with sloping banks, and must embrace a width of surface corresponding with its depth—the deeper the drain, the broader it must be at top. The cost of the stone or tile is in a manner counterbalanced by the difference in excavation. And when completed, the underdrain will require no annual repairs, while the open one will be a constant drain upon the labor of the farm, requiring bridges and frequent scouring and cleaning. If underdrains cost sometimes the most, they are unquestionably cheapest in the end—provided they are well made.

Underdrains waste no land. They may be multiplied at every twenty feet, as they sometimes are upon stiff flat clays, without excluding the plough or the scythe, from a foot of the surface. Open drains, on the contrary, if made of suitable dimensions, require a breadth of three or four feet, and the plough is excluded from as much more at their sides.

We draw no comparisons, nor do we need any, between the products of a field of habitually wet soil, or the trouble and expense of managing it, and the same field after it has undergone a thorough drainage and amelioration. Every farmer, we presume, has noticed the vast disparity in both. If there is one to whom it is not familiar, let him make the trial, and he will be astonished at the result, and at his own want of forethought in not having made it before.

III. GOOD TILLAGE.

When thorough draining has been effected, upon lands to be benefitted thereby, there is another operation which is calculated to aid in the efficiency of manures, and in the increase of farm products. This is good tillage—a perfect pulverization of the soil, and the keeping it free from weeds, which retard the growth of the crop, and rob it of its food. Good tillage is important not only as it serves to exterminate weeds, to facilitate the digestion of vegetable food, and to mix and incorporate this food, with earthy elements,—but as it breaks and mellows the soil, and enables the roots of plants to range freely in search of this food. Every farmer must have observed, that where tillage has been but imperfectly performed, as is sometimes seen about stumps and rocks, and near fences, the crop is comparatively feeble and light. This is not owing to the poverty of the soil, because the plough, as it rises to the surface in these places, deposites and accumulates there the best and finest mould of the field. The feebleness of the grain arises from the imperfect tillage which those spots receive. The old practice of carrying the main furrows to the extremity of the field, and of dispensing with head lands, is a bad and slovenly one, and ought to be every where exploded. The cut and cover practice, is still worse, as it leaves one-half, and sometimes two-thirds, of the soil, undisturbed by the plough. We remember well, that when we followed the plough in our boyish days, and knew nothing of the philosophy of ploughing, our aim was, to go over much ground, and show a ploughed surface, regarding the complete breaking up of the soil as of minor importance. There will always be a great many boys at the plough, until the importance of *good* ploughing is better understood. Good ploughing consists in breaking or turning every inch of the soil; and good tillage requires that the harrow and roller should finish, if the plough has failed to effect, a complete pulverization of the soil. A green sward becomes pulverulent as the roots of the grasses decay, and is best without a second furrow, because this turns again to the surface, to the wasting influence of the sun and winds, the vegetable matters buried by the first ploughing, and which, if left buried, would contribute largely to the sustenance of the crop. As the roots of the grasses decay, the soil becomes loose and porous, and is permeable to moisture, air and heat. Hence the advantage of fallow crops over naked fallows, and of depositing seeds upon the top of a clover lay; the sod then imparts fertility to the soil, while it enables it to derive important advantages from the co-operation of external agents.

Good tillage requires, that where practicable, as in the culture of drilled and hoed crops, the surface soil should be *kept* clean and pulverulent, while the crop is growing, for the same reason that the soil is required to be made so before depositing the seed, viz: to facilitate the decomposition of the vegetable food, to stimulate the organs of the plants, and increase the growth and product of the crop. There is no better expedient for preventing the evils of drought upon a soil, than that of keeping the surface mellow and clean. Atmospheric air and dew, both always charged with the nutritive food of plants, settles into such a surface as into a sponge, and imparts to the roots of plants both aliment and stimuli. Dews fall *upon* a hard surface, and are evaporated by the first rays of the morning sun; but they *penetrate* a loose surface, and moisten and fructify it. Hence the high repute of the drill husbandry, which enables the cultivator to keep his crops clean, and the surface of his soil mellow and open.

Good tillage has reference to *depth*, as well as quality of tilth. "There are many plants, the roots of which are found at fifteen to twenty, and even thirty feet under ground—sainfoin and lucern, for instance; even red clover well strike down to nearly three feet if the soil be a fertile loam; and some of our commonest vegetables, if it be friable or sandy, push their tap roots to about the same depth. The roots of wheat will penetrate as far as eight inches into the earth; and when sown on the crown of ridges, they have been found at the depth of twelve. We may therefore assume the depth of twelve inches as the utmost vegetative limit of corn land. Provided the soil be open and fertile, the nearer its depth approaches to 12 inches, the greater number of plants may it therefore be supposed capable of furnishing with support."—*Brit. Husb.* vol. ii, p. 49, 50. Soils should be ploughed as deep as the substratum will admit, at least once in a course of crops, if this can be reached with the force of an ordinary team; and when the surface soil is superficial, it should be deepened, as fast as fertility can be imparted, by turning up, at suitable intervals, some portion of the subsoil. The atmosphere imparts to this apparent inert earth, more or less of the elements of fertility. Baron Von Voght, increased vastly the value and products of his farm, by increasing the depth of its mould, (krume,) or vegetable pasture, in this way, in the period of sixteen years, from three to fourteen inches. Land that in the outset would only yield him fourteen bushels of rye to the acre, was by this mode of improvement brought to yield twenty-four bushels of wheat; and the improvement was not confined to a part, but extended to the whole farm, comprising some hundred acres. The reader is referred, for a detail of these improvements, and an account of the Baron's excellent system of husbandry, to No. 1, Vol. 2, of the Cultivator. And it has just been announced to us in a foreign journal, as one of the greatest improvements of the age, in rural affairs, that a plough has been invented, which breaks and pulverizes the subsoil, without turning it to the surface. Its advantages to agriculture are thus described by Le Fever, in Loudon's Magazine:—

"Smith's subsoil plough seems calculated to render the most sterile and unproductive soil fertile and profitable. Mr. Smith's most ingenious invention, by breaking the subsoil without bringing it to the surface, renders it pervious to both air and water. The same chemical changes which take place in a fallow, owing to its exposure to the action of the winds and rain, are thus brought into operation in the subsoil, whilst the surface soil is in the ordinary course of cropping; and when, after a few years, by a greater depth of ploughing, the subsoil is mixed with the upper soil, it is found to be so completely changed in its nature, as to be capable of producing every kind of corn."

Jethro Tull and his disciples maintained, that the great secret of inducing fertility, consisted in minutely dividing and pulverizing the soil by culture; and John Taylor, the Arator of Virginia, and an excellent practical, as well as scientific farmer, considered the atmosphere as the great store-house of vegetable food, where this food exists in a gaseous form. The good tillage we advocate embraces all the advantages of Tull's and Taylor's theories, without lessening the importance which we attach to barn-yard manure.

The deep ploughing of dry land, or the breaking up and stirring of the subsoil, promotes fertility, by increasing the power of the land to absorb water by cohesive attraction. "The power of soils to absorb water from air," says Davy, "is much connected with fertility. This power depends in a great measure upon the state of division of its parts, the more divided they are, the greater their absorbent power. When this power is great, the plant is supplied with moisture in dry seasons; and the effect of evaporation in the day is counteracted by the absorption of aqueous vapor from the atmosphere, by the interior parts of the soil during the day, and by both the exterior and interior during the night." The soil imbibes caloric earlier in the spring, and retains it later in autumn, in proportion as it is dry and deep, a matter of high consideration in cold climates, where the length of the summer scarcely suffices to mature the crops. The quality and dryness being the same, a soil is fertile and durable nearly in proportion to the depth of the tillage which it receives; six inches giving nearly double the pasture for plants that a three inch stratum does—and a twelve inch tilth greatly exceeding in productiveness, one of only six inches. Von Thäer calculates this difference in proportionate degrees in lands which contain a vegetative stratum of soil of four, six, eight and twelve inches in depth; provided, of course, that it be all of equal quality. If, therefore, each seed were to produce a plant, it would follow that ground which contains eight inches of depth of fertile mould, might be sown with double the quantity of that which consists of only four inches. He however admits, that this principle cannot be carried to that extent, because the action of the atmosphere must ever afford that superiority to the surface, that a cubic foot of mould, if divided into two square feet, will always produce a greater number of plants than if the seed were sown upon one foot superficial; but he assumes the value of the land to be increased in the proportion of eight per cent for every inch of mould beyond the depth of six to ten inches, and to be diminished, in the same proportion, from six to three inches, in soils of a thinner staple.—*Principes Raisonnes d'Agriculture, vol. iii. p.* 138, *s.* 735. These considerations have been hitherto but little regarded in our practice, through they constitute an important feature in the new system of husbandry.

Good tillage demands also, the extirpation of weeds. Every plant which grows upon a soil tends to impair its fertility, and weeds generally more than cultivated crops, because theyare generally the most hardy, and the greatest consumers of vegetable food. They are particularly prejudicial to crops in a dry season, as they exhaust the soil of moisture in proportion to their superficies—or the surface of their stems and leaves, some species transpiring their weight of moisture every twenty-four hours. The drill culture and deep ploughing both lessen the evil of weeds; the first tends to destroy them, and the latter to bury their seeds so deep, as to prevent the plants getting ahead of, and choking, the young crop. Clean tillage has been too much neglected in our practice. Many crops are diminished a fourth, a third, and a half, by pestiferous weeds which are permitted to seed and propagate upon the land.

Good tillage requires good implements, and these to be kept in order, that the farm work may be economically done, and well done, and done at the proper time. The disparity between old and new implements of culture is great, not only in the time employed, but in the manner in which they do the work, and in the power which is required to perform it. The old plough required a four cattle team, and two hands, to manage it, and the work, ordinarily, was but half executed. The improved plough is generally propelled by two cattle, requires but one man to manage it, and, when properly governed, performs thorough work. Harrows and other implements have undergone a like improvement. Besides, new implements, which greatly economise the expense of tillage, are coming into use, as the roller, cultivator, drill barrow, &c. so that a farm may now be worked, with half the expense of labor that it was wont to be worked forty years ago, and may be better worked withal. Mind, likewise, where it is put in requisition, and enlightened by science, is doing ten times more in aid of agricultural labor than it formerly did.

If we revert to old, and in most cases to present practices, we shall perceive, that thorough tillage has not been sufficiently attended to. Our implements have been defective, and the manner of using them often imperfect. Good ploughing is all-important to good farming, and still there is no labor upon the farm that has been more imperfectly performed, than this generally has been. Light soils seldom require but a single ploughing for the seed, if well executed; but if badly executed two ploughings are too little. Our implements are, however, daily improving, the importance of good tillage is becoming more and more apparent, and our practical knowledge is increasing.

The Farmer's Garden.

Every farmer should have a garden, for health, for pleasure, and for profit. For *health*, as nothing, in the form of diet, contributes more to this blessing, than a variety of choice fruits and vegetables for his table; while the exercise and recreation which the cares and beauties of the garden excite, are highly promotive of health. For *pleasure*—and what can afford a more heart-felt pleasure to the eye, unalloyed with pain, than the various and ever changing beauties of a well-kept garden? and what a more rich and innocent enjoyment to the palate, than a succession of fruits and vegetables, the product of our own culture and of our own soil. For *profit*—believing, as we verily do, that the labor judiciously bestowed in garden culture is amply repaid, in the subsistence it furnishes for the family. "It is incredible to those who have not had occasion to observe the fact," says Cobbett, "how large a part of the sustenance of a country laborer's family, in England, comes out of his little garden." And yet the culture of the English laborer's garden costs him virtually nothing. His occasional hours of leisure, with the aid afforded by the otherwise unproductive inmates of his family, suffices to complete the work. The rural scenery of England derives much of its interest from the beauty of the farmer's and cottager's gardens which every where abound; and many of the successful competitors for premiums, on fruits and flowers, at the horticultural shows which are there held in almost every town, are weavers and manufacturers, who cultivate their little patches of ground in the hours of exemption from professional labor. Indeed so prevalent is the taste for garden improvement and embellishment, that a man is judged of by the character of his garden. "Poverty," says Cobbett, may "apologise for a dirty dress, or an unshaven face; men may be negligent of their persons; but the sentence of the whole nation is, that he who is a sloven in his garden, is a sloven indeed. The inside of a laborer's house, his habits, his qualities as a workman, and almost his morality, may be judged of from the appearance of his garden. If that be neglected, he is, nine times out of ten, a sluggard, a drunkard, or both." The great strife every where is to get wealth—and for what? To increase the enjoyments of life. A great many of the most substantial of these enjoyments are within the reach of most men—they lie at our door—IN THE GARDEN—but we too often reject or overlook them, because they are not "dear-bought" and "far fetched."

Under our impression of the great advantages which are to be derived from the garden, to the body and mind—as a source of health, of pleasure and of profit, we intend, now that our sheet is enlarged, to devote more room for its improvement. We will shortly give a plan of a garden; and in the mean time, the scientific principles of gardening, of Prof. Rennie, which we are publishing, will be found no less applicable to the farm than to the garden. Postponing to a future occasion, our remarks upon the soil, and laying out of a garden, we proceed to give some instruction for the management of gardens already located, more particularly adapted to the present season, barely remarking, that every man who would have a good garden, must, like the late Rev. Dr. Dwight, be at least his own head-gardener—he must make himself so far acquainted with the principles and manipulations of the art, with the qualities of his soil, and the wants of his table, as to be able to superintend and direct its principal operations. He *may* obtain a good substitute, but he may be assured there are more than two blanks to a prize. And the task of qualifying one's self for this duty, is conducive alike to bodily health and mental gratification. It may become a passion, increasing with experience and with age; but it is a passion which bodes no ill to any one, but, which, on the contrary, is fraught with the best feelings of our nature.

The *preparatory business* in the garden, in the spring, is to rake together the haulm of last year's crop, and to burn it, as well for cleaning the surface, as to destroy the seeds of weeds with which the litter more or less abounds; to put the fences in good order; to take the manure to those parts where it is likely to be wanted; to procure and sharpen, if leisure permits, poles for beans, and sticks and brush for peas; to prune the fruit trees, if they must be pruned in the spring; to put the garden implements in order, and to procure a supply of good seeds. If a hot-bed is to be employed, and we strongly recommend one, it should be prepared, if not already done, in the manner recommended in pages 6, both in our second and third volumes. In these may be sown early and head lettuces, peppergrass, radishes, peppers, tomatos, early cabbages, cellery, and seeds of many annual flowers. If cucumbers are designed to be raised under glass, they should have a separate frame, or be but little encumbered with other plants.

The seeds which should be *first* sown in the open ground, and the warmest border or part of the garden should be appropriated to them, are early peas, potatoes, turnip beet, spinach, sallads, radishes, early cabbage, cellery, &c. The *second* course of sowing may embrace onions, beets, carrots, early corn and beans, sweet herbs and flower seeds. The third course will consist of the tenderer kinds, as Lima and other beans, sweet corn, cucumbers, melons, squashes, pumpkins, &c. The plants of the garden possess different degrees of hardiness, and require different temperatures to bring them forward. Some will germinate and grow at a temperature of 45° to 55°; and will not suffer from slight frost; while others will not grow unless the temperature is higher, and are liable to be injured by the slightest frost, or by cold damp weather. When corn, put in the ground very early, shoots to the surface, it is deemed early enough to plant melons, cucumbers and other vines for a main crop. All roots, to be planted for seed, as turnip, beet, carrot, parsnip, onion, &c., should be put out as early as the condition of the ground will admit, where the soil has been well prepared. They should be put at sufficient distance from each other to permit their seed stocks to spread, and to enjoy the full benefit of light and air. No two kinds of the same family of plants should be put out for seed near each other, not even the turnip and cabbage, as the seed will thereby become adulterated.

It is important in planting, for most crops, that the ground should be well dug, or ploughed, to the depth of eight to ten inches, to which depth the roots of most plants run, and for the tap rooted plants, as beets, carrots and parsnips, it were better to have the tilth twelve to fourteen inches. The ground should be fresh turned or stirred when the seeds are put in, and either trod, on the lines where the seeds are to be deposited, before planting, or pressed upon them after they are covered with earth. Seeds should be planted no deeper than is required to keep them moist.—See our article upon the germination of seeds, in another column.

This is the season for transplanting. How often do we hear people regret, on seeing their neighbor's gardens abound with choice fruit, that they too had not planted in times past. The season for transplanting fruit trees is unavoidably limited to the season of defoliation, when the growth is dormant; and the excuse of men generally is, that they either had not time, or forgot, to put out trees when alone the work could be done. This is very much like the man who suffered his family to be drenched by every rain, because he could not patch his roof when it stormed, and because there was no need of doing it when the weather was fair. What short-sighted mortals, to undergo a life of privation, of many of the richest gifts of Providence, rather than incur the trifling outlay of expense and labor—of a few cents and a few hours—to secure those blessings for themselves and families? Mercenary considerations alone—the ruling passion—should prompt to the planting of fruit trees. One of our neighbors has been in the habit, for years, of receiving from $500 to $1,000, for the fruits of his garden, after supplying himself and a large circle of friends. Another once pointed to a fine black heart cherry tree in his garden, and remarked, "the fruit of that tree has brought me fifty dollars." The tree might have cost him fifty cents, and the planting fifty minutes of time. This was ten years ago, and the tree still continues to render its annual tribute. We know a Siberian crab, the fruit from which brings the proprietor from eight to twelve dollars every other or bearing year; and of a farmer's garden, from which the currants, besides the liberal use of this fruit in his family, afford an annual income of some twenty dollars. The planting of the cuttings for these did not cost three hours' labor.

But in our zeal to commend the practice of planting, we must not forget to give some hints as to the method of doing it. A tree is like a plant of corn, or of any other farm crop: it will prosper and repay for labor, according to the soil in which it is placed, and the attention bestowed upon its culture. The soil must be good, to afford the necessary food for its sustenance and growth; it must be loose, that the roots may penetrate readily in search of food; it should be free from habitual wetness, as an excess of water will injure, if not destroy it. Like farm crops, too, it depends, for its development, and the maturation of its fruits, upon the unobstructed agency of light and air. Hence it should not be planted below its natural depth in the soil, nor shaded by other trees, nor encumbered by shrubs, weeds or tall grass. Water is the medium by which food is transmitted from the soil to the plant, and is required, therefore, to be always present in the soil to ensure the growth of plants. In transplanting, make your holes as deep and broad, not as the roots require when transplanted, but as they are likely to extend the first season after being transplanted, and fill this hole, as you put in the tree, with rich surface mould, or at all events the lower stratum, which the roots are destined to penetrate in search of food; tread the earth firmly around the roots, when they are covered, to bring it in complete contact with them, and to prevent the evaporation of moisture, which latter evil will be further prevented by spreading some coarse litter upon the surface about the stock of the tree. Two or three potatoes may be thrown in about the roots, before they are covered; and a bucket of water, thrown in when the hole is partially filled, will tend to bring the earth in contact with the roots, and supply needed moisture. The transplanting of evergreens should be delayed till the new growth has commenced, in this the latitude the last of May.

Samuel Preston on the Apple.

We find in the second volume of the Memoirs of the Philadelphia Agricultural Society, an interesting letter from this old acquaintance, on the culture of the apple tree. Mr. Preston was an early settler at Stockport, in the county of Wayne, Pa.; he planted much orcharding, and personally superintended its management. From this letter we abstract the following hints:

A loose gravelly soil Mr. P. believes is best adapted for an apple orchard, a high and airy situation, and a north aspect, as most secure from the late frosts in the spring. He recommends that horse dung and litter be spread around the tree, to keep the ground loose, and free from sod, and, he might have added, to prevent evaporation of moisture, in a dry time. The trees whose fruit was affected with the bitter rot, Mr. Preston caused to be stripped of their bark from the roots to the limbs, at mid-summer, a practice which we have seen successfully performed to renovate trees that had become cankered and mossy. This operation prevented the bitter rot upon the fruit, though it injured the vigor of the trees. We think a better, and perhaps the *best* mode, of giving health and fruitfulness to apple trees, on dry bottom lands, is, to take off the ross, and moss, with a hoe, or other instrument, and then to wash the body with a strong ley, late in May, or early in June. This destroys insects, and imparts health and vigor. His mode of destroying the caterpillar, was to go early in the morning and twist their nests out of the tree with a stick or pole. The Pickering brush is better. He recommends the planting of natural trees, and that they be grafted with choice fruit when they have attained a good size—and commends the seek-no-further—now considered but a second rate apple. He sowed plaster *under* a part of his trees—a frost followed;—the blossoms were all destroyed, *save upon the trees under which the plaster was sown.* He thinks the plaster attracted the moisture, and prevented frost. This we doubt.

From Mr. Preston's experiments in grafting, we abstract the following: He inserted grafts which came from England and France, which generally grew. He received plum grafts from Esopus, in midwinter, which had come from Holland. He laid them in his cellar till the proper time for inserting them, and they grew well. He made cuttings the 15th September, carried them two days' journey in his pocket, till they were much shrivelled, preserved them till grafting time *under a sod,* then grafted them, and they all lived. He cut grafts in October, kept and grafted them in the same way, and they all failed to grow. Grafts were cut and sent to him in June, when the laeves were nearly of full size—they grew and did well. He took grafts from Albany in March, preserved them carefully, inserted them properly, and yet only two out of many lived.

Rotation of crops.—There need not be a stronger argument adduced, in favor of the system of alternating crops, than a condition which is generally inserted in the Scotch leases—*prohibiting the tenant from taking two white crops,* i. e. of small grains, *in succession,* from the same field—because such repetition tended to impair the intrinsic value of the land.

Long Manure.—"Were the practice general, [of using dung in its unfermented state] it would add above twenty millions sterling to the produce of the kingdom." So said Arthur Young. This should be received here with the qualification, that it should be always applied to Indian corn, potatoes, and other hoed and autumn-ripening crops. Unfermented manure, when applied in any quantity, *is* prejudicial to the small grains generally, and to all crops which ripen their seeds at mid-summer; but *it is not* prejudicial to the crops we have named, or others, which ripen their seeds in autumn. The farmers of Schoharie, Otsego, Oneida, Madison, &c. who are in the habit of *summer yarding* their dung, under an impression that it improves, like wine and cheese, by age, need not be afraid of hurting their corn and potatoes, by feeding these crops with long manure, and to them the remark of Arthur Young, applied under our limitation, may be turned to vast profit.

On the use of Gypsum.

There is not any longer doubt, in our mind, of the advantage of applying gypsum to all our meadow lands, in the spring, which are beyond the influence of marine atmosphere, and which are habitually dry. There are instances recorded, to be sure, of its not producing perceptible benefit the first year, and some instances where it did not seem to operate even the second year, and yet it ultimately developed its fertilizing properties.

We do not design now to discuss the question, *how* gypsum does operate—but to inquire and state, from the facts within our reach, to what crops its application is particularly beneficial—on what soils its effects appear to be greatest—how much should be applied to the acre, and at what season it is best applied. We are satisfied, that if the value of gypsum was better known, it would be much more extensively used than it is; and that the more it is used, the greater will be our agricultural surplus.

Gypsum, according to Chaptal, consists of

Pure calcareous earth, or lime, ...	30 parts, or	33
Sulphuric acid, ...	32 "	43
Chrystalized water, ...	38 "	24
	100	100

It requires from 450 to 500 times its weight of water to dissolve it. When pure, it does not effervesce with acids; it is insipid in taste, and free from smell. A simple mode of trying its quality, consists in putting a quantity of it pulverized into a dry pot over the fire, and when heated it gives out a sulphurious smell. If the ebullition, or bubbling, which then takes place, is considerable, the plaster is good; but if it is not, it is considered indifferent; and if it remains motionless, like sand, it is not thought to be worth any thing. Its colour is white, gray or blue. Its effects, in benefitting agriculture have been greatest in Germany and in the United States. Its benefits in Great Britain and France have been less certain.

The soils upon which gypsum operates most beneficially, are the light, dry, sandy and gravelly. Upon soils containing little or no vegetable matter, its effect is trifling; but if these lands are dressed with dung, the gypsum then produces a great effect; and the dung being present, the poorer the land, the greater its benefits. It seldom produces any sensible effects upon wet grounds, and frequently none upon stiff clays.*

The crops which are most benefitted by gypsum, are the clovers, lucern, Indian corn, peas. There are some few cases noticed of its being found beneficial to wheat, and other small grains, but it is the general received opinion that it does not operate directly on these. But gypsum may be made indirectly beneficial to all crops which are grown upon a clover lay, by causing a greater growth of clover, which becomes food for the crop which follows, and which is abundant in proportion to the rankness of the previous clover. Its effects upon turnips is doubtful; and some will not allow that it is beneficial to potatoes. Davy lays it down as a fact, that it is most beneficial to those plants which always afford it on analysis; and the small grains are not found to contain it at all. Many instances are given where its application has doubled and tripled the clover crop.

The quantity which should be applied to the acre is a point quite unsettled; and it should probably be varied according to soil and circumstances. John Taylor, of Virginia, and Judge Peters, of Pennsylvania, concurred in opinion, that on lands where it was applied annually, one bushel an acre was an ample dressing. In Europe it is recommended to dress with or five or six bushels an acre. We have generally sown but a bushel; but last spring, by way of experiment, we doubled the dressing on a portion of a meadow, and found the grass there much the heaviest. It is advisable to try it in different quantities, and to note the result of each, as a guide to future practice.

The time of applying gypsum is generally in the spring, sometimes as late as May or June. The writer of British Husbandry recommends, with much plausibility, that the gypsum be applied to clovers semi-annually, viz. soon after the crop is mown, in summer, and in the spring, just after the plants have begun to shoot. We will be thankful for memoranda of any experiments that may have been made in this practice in our country; and also, *whether it produces a better effect when laid on in dry, than in wet weather?* The work from which we have just quoted, dwells with emphasis on the importance of having the gypsum attach to and remain upon the leaves of the young plants—and repeats the charge to sow it when the leaves are wet with dew, or with a recent light rain, —and never just preceding or during a rain. Prof. Low says, that mineral substances, as powdered lime and gypsum, are absorbed through the pores of leaves, when scattered upon them. A watery temperature, it is alleged, at least arrests its effects, and seems to suppress them altogether if the gypsum has been calcined, a process which it is sometimes subjected to, to facilitate its reduction to powder. Burning, however, merely expels the chrystalized water, without otherwise altering the gypsum, the strongest heat not being sufficient to expel the sulphuric acid. When applied to tillage crops, it should be either sown broadcast in spring or scattered upon the hills or drills of the growing crop. Upon the principle quoted above, the latter would seem to be the better practice in regard to hoed crops; though our mode of applying it to corn has been to sow it broadcast before the ground is harrowed for seeding. When applied at the rate of five or six bushels to the acre, the effects of a dressing have sometimes continued some four or five years. The most common practice is to sow it annually, upon the crops and grounds likely to be benefitted by it, and to sow it in quantities from one bushel to two bushels on the acre.

To determine the capacity of gypsum for absorbing moisture, an ounce and a half, in fine powder, was exposed to the air during three foggy nights, and afterwards carefully weighed, when it was found to have gained not quite half a grain in weight. This fact overthrows the theory, that plaster is beneficial on account of its capacity and tendency to imbibe moisture from the atmosphere.

The benefits of gypsum are so palpable in our country, upon clover and some other crops, and indirectly upon nearly all, that we cannot but hope these remarks will serve to extend its use upon our farms, and to induce many to try it, who are experimentally ignorant of its fertilizing powers.

Economy of Manures.

Parkhurst, an eminent British farmer and agricultural writer, who resided some years near Baltimore, in speaking of our economy in manures, says, that

> "The farm yard manure in that country (the United States) is of little value; for it is ill-managed, the straw weak, and the generality of the horned cattle so poor, that their dung is light and worthless."

Now if this charge be true, as there is too much reason to believe it is, let us not scold at the exposure of our fault, but set to work in earnest to remove the reproach, by making our straw stronger, our cattle in better condition, and our manure, consequently, more abundant and valuable.

An advantage of a calcareous soil.—Calcareous soils, and soils dressed with lime, are stated, in British Husbandry, to possess the advantage of guarding the sheep which graze upon them from the rot, and also from the foot-rot.

The new lands of Kentucky wearing-out.

"Injudicious cultivation for a series of years," says the Franklin (Ky.) Farmer, "has robbed much of the soil of Kentucky of its freshness and fertility; and her agricultural sons must now *either content themselves with more sparing crops than repaid the labors of their fathers, or seek for richer and more fruitful fields in the far distant west or south.*" Kentucky became a state, we believe, in 1791. If fifty years "injudicious cultivation," has sufficed to impoverish the so late fertile soil of that state, it affords but another evidence that our system of husbandry is wretched bad, and shows the necessity of a prompt and thorough change. The Flemish soil is generally light and moist, and much of it was absolutely incapable of growing farm crops in its natural state. Yet the skill and industry of the Flemings have rendered it the most productive agricultural district in Europe; and its fertility is still on the increase. Houston, a distinguished British agricultural writer, has shown, that the Flemings get twice as much produce from their lands annually, partly by double cropping, as the English get from a like quantity. That country has been improving in its agriculture for eight hundred years. "In the Pays de Was in Flanders," says Sinclair, "the soil was originally a barren white sand, which by a slow but sure process has at last been converted into a most fertile loam." The county of Norfolk, in England, but a few years ago, was perhaps the least productive district in England; but by judicious management it has now acquired a fame in husbandry, which, in the words of the author just quoted, far surpasses that of other districts far more fertile. "Necessity is the mother," not only of "invention," but of industry; and hence, in poor districts, where nature has done least, we find men doing most; and hence rich lands are suffered to deteriorate, while art and industry are augmenting the fertility of poor ones.

---

* See communication of Mr. Bayard.

Cicero, in eulogizing Socrates, passes a just encomium upon that philosopher, when he says—"He conceived the thought of bringing down philosophy from heaven, to place it in cities, and introduce it into private houses; humanizing it, to use that expression, and rendering it more familiar, more useful in common life, more in the reach of man's capacity, and applying it solely to what might make them more rational, just and virtuous." Now we want a Socrates to do all this for our farming community—to bring down the philosophy of science to the useful purposes of life—to place it in our dwellings—to apply it upon our farms; to ruralize it, render it more familiar, more useful, more in the reach of our capacities, and to make it the companion and guide of agricultural labor. This would teach us *when*, and *how*, our soils become exhausted, by "injudicious management," and instruct us in the means of *preventing* the loss of "their freshness and fertility," without diminishing their products or income. It would teach us, also, how to render lands productive which are not so naturally, and to simplify and economize labor in all the departments of our business. But alas! we have no Socrates to render us these kind offices—no schools in which the young farmer can acquire these useful aids to his labor—no public guardians that take cognizance of these highly interesting concerns. Our only alternative seems to be, that which necessity often calls forth on emergencies—we must each become a "*Rural Socrates*," and like the Swiss peasant, upon whom this title was justly bestowed, and whose memoirs we intend shortly to notice, become self-teachers, in the philosophy which instructs, dignifies and rewards rural labor. The means are accessible, and success, to the young at least, will be the result of perseverance.

We subjoin to our remarks a further extract from the article quoted from as our text, with remarking, that we very much fear that his object, scientific knowledge to the farmer, cannot be reached through the means he proposes—geological surveys. This may do something, but no great. Science rows with *one* oar—practice with *another*—and the boat will only go ahead, by the propelling influence of *both* oars, operated upon simultaneously. Now geologists, very properly make the *science* of geology their study, and, were they disposed, they seldom have the practical knowledge necessary to render it of great service to the agriculturist. We must combine the practice with the theory if we would gain useful instruction. And the only way we can conceive of doing this, is to have schools of theory and practice combined—that when boys find themselves at fault in practice, they may discover the cause and apply the remedy from the theory; and that where the theory is obscure or doubtful, they may solve their doubts, and establish their principles, by resorting to practice. If a new implement, or a new principle, is recommended for our adoption, prudence suggests that we try before we adopt it. If an operation in husbandry fails to realize our expectations, we naturally wish to know the cause of failure, and the means of averting it in future. This we generally alone learn from the philosophy of science, which seems to have been dispensed to us for the wisest purposes—to incite to study, to reflection, and to perseverance. But in our enthusiasm on subjects of this kind, we had like to have forgotten our promise, which was to give another extract from the Franklin Farmer. It follows:

"But in his first efforts to improve, the practical farmer is met by difficulties which he cannot surmount alone. He has been bred in the school only of *practical* agriculture, and though he has learned, and practised with success, many of her best lessons, he is now at fault,—and is seen to sink back in apparent despair, and exclaim, what can agriculture do without the light and help of science? He has seen a sickly and dwarfish plant growing where in years gone by it was vigorous, thrifty and prolific, and he does not fully understand the cause. He has seen his fields waving with a luxuriant and promising crop, and just as his hopes were about to be crowned, he has put the sickle to the harvest, and gathered little but disappointment and vexation. He asks himself the reason why,—in vain, for practical agriculture has not taught him that. With unwearying perseverance he tries again the fortune of another season, in hopes that by different cultivation, or more extensive manuring, or a change of crops, to meet with more success. But he is unacquainted with the character and condition of his soil, with the qualities and properties of the different manures, and with the adaptation of particular crops to particular soils, and again his well meant efforts are but half successful. He is constrained to acknowledge that without the light of science he is but groping in the dark, along a path which may lead to fruitfulness to-day, and to briars on the morrow."

Staggers in Swine.

Our attention has been drawn to this subject by the loss of several pigs in our neighborhood, and one of our own, by a disease denominated *the staggers*. We find in the second volume of the Memoirs of the Philadelphia Society for Promoting Agriculture, a communication from J. P. De Gruchy, of much interest. Mr. G. kept from 100 to 250 hogs, and lost annually several—six, eight and a dozen being taken in a few hours. They were generally attacked in the month of September. The hog would all at once turn round very rapidly, and if assistance was not at hand, would in less than half an hour die. Bleeding and brimstone were applied with but little success. At length one of his workmen put into his hands an old pamphlet printed in the year 1707, in which he found the following prescription for what he considered the staggers: "You will see a bare knob in the roof of the mouth, cut it and let it bleed, take the powder of loam and salt, rub it with it, and then give him a little urine, and he will mend." Mr. De Gruchy employed the remedy for several years, with almost unvarying success; but although his hogs generally recovered, they never throve so well afterwards. The disorder is generally confined to pigs and hogs of middling size.

Mr. De Gruchy mentions another disease which attacked his best hogs (in pen) in August, and which carried off thirteen in a few days. He denominates it the *sore throat*. The hog would often be dead in ten minutes after he was attacked. He bled the fourteenth that was attacked, and had him carried and laid in a clover field, and he recovered. The remainder of the hogs were then turned into the clover field, and the disease disappeared. This was done annually afterwards, and the hogs had neither staggers nor sore throat. It is now a well established opinion, that hogs should have access to pasture, in summer, or at least to the earth, to preserve their health.

On Climate, and the Means which may be Employed to Modify it.

There are considerations in regard to climate, which should obtrude upon a man who is about to fix his residence for life; and there are artificial means by which it may be partially modified by him who is already located in a bad one. By climate, we do not mean portions of country which are bounded by parallels of latitude; but we mean a district, a tract or a farm, differing in temperature, from local causes, from other districts adjoining. The local cause of this difference may be elevation, contiguity to marshes or waters, aspect, capacity of the soil for imbibing or retaining heat, &c. All of these circumstances have a bearing upon the products of agriculture, and most of them upon the health and comfort of the population.

A district is rendered comparatively cold, by being mostly covered with wood, by the contiguity of marshes, by being elevated above the surrounding districts, and by open exposure to bleak winds. The two first render the air moist, and cause a greater range between the extremities of heat and cold; the rays of the sun are partially excluded from the ground; evaporation is prevented; and the miasma which is often generated is prejudicial to the health of man and beast.

Altitude has a manifest influence upon farm crops. One hundred and eighty feet elevation produces a difference in temperature equal to a degree of 69 miles of latitude. In latitude 54 and 55, in Scotland, Sinclair tells us, 600 feet above the level of the sea, is the greatest height at which wheat will grow, with any chance of repaying the husbandman for his labor.

The quality of the soil and subsoil have an influence upon the temperature and products of a farm. If these are hard and retentive, and particularly if flat, the surplus rain-water does not pass off; solar heat is prevented from penetrating; the soil is cold and sour, and the finer crops cannot prosper. But if the soil consists of sand, gravel, or friable sand loam, and the surface has much of a slope, the excess of water passes off, the heat penetrates freely, and vegetation is healthy and comparatively vigorous, even though the subsoil is somewhat tenacious. A moderately undulating, or rolling surface is, therefore, better for farm purposes, particularly for arable husbandry, than a flat surface, or than a precipitous one, where the finer particles of the soil are liable to be washed into the valleys by heavy rains.

Aspect, in hilly or mountainous districts, is a matter of consideration with the farmer. The soil on the northern slope of a hill is generally richer than on a southern slope, from the circumstance that it is less liable to be wasted by alternations of freezing and thawing, and the effects of rains: But that on the southern slope, being more exposed to the influence of the solar rays, is warmer, and more congenial to grain, and other tender crops; while the north is best adapted to pasture and meadow.

The artificial means of ameliorating a severe climate, consist in diminishing the wood, and exposing more of the surface to the sun's rays; in draining the marshes and wet grounds; in planting the crowns of the hills, and the exposed quarters of the farm, with timber or other trees, where these points have been imprudently bared of their wood; by making small inclosures, divided by stone walls, hedges or belts of timber; by cultivation, and by ridging, and by blending light and friable soils with those which are heavy and stiff. By employing such of these means as are best adapted to the location, much may be done to ameliorate climate, and to render it salubrious. When the surface of the ground is broken, water subsides into the soil, instead of either resting on it, or being thrown off in torrents, often a source of much mischief; and if the surface is formed into ridges and furrows, water is drained off, and the soil is enabled to imbibe the salutary rays of the sun, and the genial influence of dew and air, and may be worked earlier in the spring. We consider it a great defect in northern husbandry, that on flat surfaces, and tenacious soils or subsoils, the lands are not more generally thrown into narrow ridges and furrows, that the winter and heavy rains may pass off as they fall. The above remarks, so far as regards the effects of draining and culture upon climate, we have seen verified in our own practice. The small spot which we improve, when it came under our care, contained much low marshy ground, and abounded in springs, and in wet seasons with waters concentrated in pools upon the surface. The tendency of all this was to render the air cold and humid, and unhealthy, and the crops liable to be injured by late and early frosts, from which the neighboring district was exempt. A thorough system of draining and good cultivation has effectually remedied these evils, and enabled us to work our lands earlier, and to bring our crops to earlier maturity—while the healthiness of the neighborhood has been correspondingly improved. We have done something towards sheltering our grounds, by preserving, where we could, a growth of wood on the exposed quarter, by planting it at other points, and by the culture of live fences.

As marshes and shallow waters are prejudicial to the health and climate of a neighborhood, large bodies of water, like those of the great lakes, which do not freeze over in winter, have a contrary tendency, and particularly to ameliorate the severity of winter, by the quantity of caloric which they give off at that season. Thus the mean temperature of the winter months is several degrees lower at Albany and Buffalo, than it is at Rochester and Oswego, or any where along the southern borders of lakes Ontario and Erie.

In our northern latitudes, every artificial means that is available should be employed to ameliorate the climate. We have many crops that require a combination of favorable circumstances to bring them to high maturity, and in a vast many instances their product is greatly diminished by early and late frosts, which in many cases might be averted, partially if not wholly, by a timely attention to the suggestions which we have now made. Indian corn, for instance, in late years, in order to ensure its maturity, requires to be planted on a warm dry soil, in which sand greatly preponderates, which imbibes heat readily, can be worked and planted early, and that the auxiliary aid of unfermented manures be employed to increase the warmth.

Olden Times—1795.

CANKER-WORM.

Referring again to the first volume of Memoirs of the Society of Agriculture, &c. the next paper that we shall notice, gives us the character and habits of the canker-worm, and suggestions for preventing its ravages upon our apple trees, by Dr. S. L. Mitchill.

The Doctor tells us, that Forskall has enumerated twenty species of insects which prey upon the apple tree, seventeen of which are *phalœnas*, (millers,) of which the canker-worn is one, and more destructive than the rest. This insect in its miller state, conceals itself in holes and under the shaggy bark of the tree. The male has wings, and flies, but the female appears to have no wings, and ascends the tree by creeping up the body. The doctor had noticed them as early as the 25th March, on Long-Island, which was the period of their copulation. Soon after the female, guided by instinct, crawls towards the extremities of the branches, and deposites her eggs where there is likely to be an abundance of foliage to nourish her progeny, and dies. The same degree of heat that causes the leaf to expand, vivifies and hatches the eggs. The worm attacks the tender foliage, the elaborating organs, and thus deprives the blossoms of their proper nourishment; and if the blossoms do expand, they are either destroyed, or become abortive, for the want of elaborated food, which the leaves can only furnish. The tree becomes unhealthy from the like cause, and is cankered and covered with moss. Such is a brief notice of the habits of the canker-worm.

As preventives of the injury they cause, the doctor suggests the scraping off all the loose fragments of bark, an excellent practice from other considerations, and which may be readily done with a hoe, taking care not to wound the fresh young bark; also, tarring the bodies of the trees, or other impediments to prevent the ascent of the females. For the latter purpose, a hair rope has been recommended, wound once or twice around the bole of the tree. By making the bole clean and smooth, the insect is deprived of its winter shelter, and is exposed to destruction, in its ascent, from birds, which soon begin to make their appearance.

The canker-worm does great injury to orchards, particularly at the east. The late T. Pickering turned his attention to the means of prevention, and made a brush, similar to a bottle brush, though larger, and of a conical shape, which being attached to the end of a pole, is effectually employed in destroying the worm after it has formed its web upon the tree. This brush, denominated the Pickering brush, and sold by our seedsmen, we have successfully used for many years. It is our practice, when the leaf buds of the apple tree begin to burst, to send a man or boy into the orchard, with this brush, properly rigged, while the dew is on, or the weather damp, at which times the young worms are concentrated at a point which may often be covered with the thumb, and hundreds of the nests, with their inhabitants, may be destroyed in two or three hours. When within reach, they may be crushed by the hand, and when farther removed by the stiff hairs of the brush, which, by a turn or two, collects and brings down the web. At this period almost every nest may be descried; and if any should escape notice, they may be seen on a second visit, which may be made a week afterwards, when the worms and their nests become more conspicuous. A day has served to go through an orchard of three or four hundred trees, planted from ten to fifteen years, and to destroy these pests in their germ.

ON PRESERVING AND PROPAGATING TREES.

This is a report from a committee appointed to examine this subject. It relates principally to forest timber, a subject which is daily acquiring increased importance with us. The principal points suggested in this report are the following:

1. That woodlands should be inclosed, to guard the young growth from cattle and sheep.

2. If the wood is old and decaying, it is most profitable to cut clean, and let the land lie for a new growth, which will thus have an equal advantage of sun and air. If inclosed, nature will do all the rest, and much better than art or labor.

3. This mode of propagating wood and timber is profitable upon poor land. One of the committee purchased ten acres of poor land, which had just been cleared of its wood, at $2.50 per acre; and in twenty years the growth of this wood had enhanced its value to $12 an acre.

4. When sprouts have been nipped or bitten by cattle, cut them close to the ground: new sprouts will immediately shoot up, straight and vigorous.

5. Woods ought not to be thinned too much, lest it cause the decay of trees, and by encouraging the growth of weeds, &c. prevent their growth. It may be added, it bares them to the unaccustomed force of the winds, which often does serious injury, as is often witnessed in groves of sugar maple, which have been deprived of their protection, by the other timber having been cut away.

6. Woods intended for timber are excepted from the preceding rule; as that growing in thick shade, and moist air, is not so hard and tough as that which has the benefit of the sun and free air. Upon this we remark, that *timber* trees ought to be of the second, not of primitive or forest growth. The best timber trees are from isolated clumps, or belts along permanent division fences, as we have seen in Pennsylvania, of second growth, where trees are thin from the outset, and not where they are made so by the axe, after they have attained to large size. These belts, by the bye, we particularly recommend to the notice of our readers, not only as an economical mode of obtaining timber and fuel, but of giving shelter to cattle and crops, and as imparting beauty and health to the farm and landscape. The remark is particularly applicable to the bleak exposures of the farm, as the west, north and north west. Crops are specially benefitted by the shelter they afford in winter; and both cattle and crops are benefitted by them in summer.

7. Recommends, that upon all poor and stony lands, unprofitable for tillage, the growth of trees be encouraged, as the most profitable use to which they can be applied. It also gives directions for planting the acorn, the oak being deemed the most valuable tree to plant; but these directions apply to the seeds of many other forest trees, many of which are worth propagating in this way, as the maples, beech, ash, &c. The directions are, to gather the acorns in the autumn; make a bed of loam two inches deep; on this plant the acorns two inches deep, we should say one inch; over them lay another bed of six inches of earth; over that another layer of acorns, and so on, as far as occasion requires. Cover the whole to preserve them from frost, and plant them where they are permanently to grow. We consider the last as unnecessary. The seeds of all forest trees, as they fall and lay, are exposed to frost naturally, and yet they do grow; and so they will grow if artificially managed.

8. Directs the mode of planting the seeds where it is intended to grow permanently,—which is, to make a hole with a pick axe, drop the acorn, and cover it with two inches of earth. We dissent from this. A plantation is as much benefitted, by the ground being previously broken and pulverized by the plough and harrow, as a cultivated crop—and it should be so prepared before the seeds of forest trees are deposited in it. A mistaken idea is too common, that trees and shrubs should live, and grow, and thrive, any where they may be planted, without reference to the nature and condition of the soil in which they are planted, or to the care which is afterwards bestowed upon them. Trees are like cultivated crops. They derive their principal nourishment from the soil. The more food they can find there, adapted to their wants—the more facility that is afforded them, by a mellow soil, of extending their roots, to obtain this food—the greater will be their growth, and ultimate product. A man who would derive extra advantage from his trees, must bestow upon them the care and attention he would upon a favorite animal or favorite crop.

9. Directs, as another mode of propagating the oak, to *pare* the earth with a plough, to plant the acorns in rows, and cover them with the turf. We would, for the reasons already stated, substitute, *plough and harrow well*, for pare, and direct the acorns to be then planted.

10. Recommends that the society take steps to encourage the cultivation of wood upon the sea coast, not only as a means of furnishing fuel and timber, but as a means of fertilizing the soil: the leaves of forest trees which fall in autumn, producing a rich mould.

Efficacy of nitre in steeps of seed grain—a paper by Robt. Johnson, Esq. then a senator from Dutchess. After stating his own experience of its benefits in a steep for seed corn, he states a prominent case of its benefit to seed wheat. His neighbor sowed his main crop of wheat at the usual time, a fortnight later he sowed another parcel, the seed of which was steeped in a pickle in which salt petre had been dissolved. The latter ripened first, although the seed and the soil were the same as the first, grew four inches longer, and was at least twenty-five per cent better than the early sown, and which had not received salt petre.

Analogy between Medical and Agricultural Education.

The physician and surgeon, to qualify them for their professions, of preserving life, are required to study the anatomy of the human frame, the functions of every part of the system, and the nature and quality of whatever is requisite to administer to its wants, or to avert or remove the ills which it is heir to. Without this knowledge he can but *guess* at the cause or seat of disease, and of course his prescriptions must be questionable, and often hazardous. A knowledge of these matters cannot be acquired by bare practice. It must be obtained from the teachings of ages—in schools of medical science—in the dissecting-room. Hence the laws of every civilized people require in the pupil this preliminary study, before he is permitted to practice the art professionally. And no intelligent man, who justly appreciates the necessity of the science to perfect the art, likes to trust his health and his life, in the hands of a pretender, who knows nothing of the great principles of the business which he professes to practice.

So with husbandry. It embraces principles of science, upon which good modes of practice must necessarily be based; and without a knowledge of these principles, the labors of the farmer, like the prescriptions of the quack, must be either *guess work*, or confined to the routine in which he has been instructed. His soil and his animals are liable to sterility and disease which he is ill-qualified to cure. Unless he knows something of the composition of the one, and the anatomy of the other, as branches of natural science, he is not likely to discover the true cause of an evil, nor to apply to it the right remedy. We will give a single illustration in the alternation of farm crops. It is now universally admitted, that the alternation of crops is highly conducive to good husbandry. But why is it so? Science, who expounds the laws of the Creator, in regard to inanimate matter, not only furnishes a satisfactory answer to the question, but suggests the classes of farm crops, and the order of succession, that ought to alternate and follow each other. Again, —gypsum, lime, marl and ashes, are beneficially applied to some soils, to some crops, and in some seasons, while they are not beneficial upon other soils, to other crops, or in other seasons. Science can alone explain these seeming contradictions. In a school of scientific and practical agriculture, in which a series of experiments should be continually going on, these problems would ere long be solved; rules of practice would be laid down; the results, and the natural causes of these results, would be explained, and the community, and every member thereof, who had a latent spark of improvement, or the ambition to improve his condition, would seek for, practice, and profit, from the discovery. In this, agriculture differs from most other professions. While in other professions, the benefits of improvement may be monopolized by an individual, or a small number, improvements in husbandry are accessible to all, who are not too conceited to learn, or too indolent to practise, from the examples of improvement which are every day making around them.

The result of the analogy which we have drawn, between medical and agricultural education, is this,—that science is equally beneficial to both; that while the one is destined to preserve and prolong life, the other is charged with nourishing it, and of multiplying its comforts and enjoyments; and that both are, consequently, entitled to the protecting care of an enlightened community.

Pruning Fruit Trees.

This operation is directed to be performed, by a writer in the Horticultural Register, *in the winter*. The common practice is to prune *in the spring*. Both we conceive to be wrong. It is unnecessary again here to repeat our reasons, for pruning *at mid-summer*, as we have already twice published them in the Cultivator. We will only add, that our opinion in this matter is fortified by the philosophy and practice of the late Rev. Dr. Dwight—(see last Cultivator)—and by four years' observation and practice in our own grounds. We prune in the last of June and first part of July. We earnestly recommend a *trial* of the practice.

The objects of pruning are at least three fold. We trim shade trees to produce symmetry of form. We trim forest trees to produce a handsome and valuable bole, or stem, for timber. And we prune fruit trees for the double purpose of giving them a good shape, and of inducing them to bear well. To the pomologist that shape is most handsome, in a fruit tree, which indicates the best bearing qualities. It is remarked, particularly of the apple, that upright shoots produce less abundantly than those which grow horizontal, or deviate materially from an upright form. Hence, in forming the head of a young apple tree, it is customary to take out the upright shoot, when the tree has attained a proper height, say seven to nine feet, and to leave three or four laterals or limbs to form the head. And as pruning does not increase the quantity of wood, but has a different tendency and effect, by lessening the leaves, which are the organs of nutrition, the upright shoot should not be taken out until the laterals have acquired considerable wood and foliage. In pruning fruit trees, all limbs which are likely to interfere with each other, should be taken out while they are small. The head of the tree should be kept open, so as to admit light and air, essential to the maturity of the fruit. In pruning all trees in the nursery, the limbs should be left always upon one-third of the stem, that is, only two-thirds of the stem should be denuded of limbs.

Tunis Mountain Sheep.

About thirty years ago this breed of sheep excited much attention in Pennsylvania, and the more southern states, several having been imported by Judge Peters and Commodore Barron some years before that time. They belong to the broad-tailed, or five quarter species—the tail weighing from six to sixteen pounds. These sheep were extolled for their great weight, good health, fineness of meat, early maturity, and quality of fleece. Individual animals weighed 175, 192, and 214 pounds alive. Several of the Philadelphia butchers and victuallers certify that their meat was uniformly superior to any in the market, that they fatten with little food, and are uniformly healthy. Maj. Raybold butchered 2,000 broad-tailed sheep, and is decidedly of opinion the meat is better than that of any other sheep, and that the Tunis sheep fattened the most speedy; and "I have slaughtered," says the Major, "half and three-quarter blooded lambs, many of them weighing fourteen and fifteen pounds a quarter." We should be very much obliged to any correspondent, who would furnish us an account of the present condition, value, &c. of these broad-tailed sheep.

It is matter worthy of note, that the Merino sheep of Spain are supposed to have attained their present high character from crosses with rams from the north of Africa, perhaps of the stock from which the present Tunis breed have descended. These crosses, and consequent improvement of the Spanish flocks, are thrice noticed in history—first in the time of the Romans, by Columella; thirteen hundred years after that by Pedro IV. of Spain; and again by Cardinal Ximenes, two hundred years subsequently.

Humus—Humic Acid.

As we have already observed, these are terms applied to the fertilizing matters in the soil, which are produced by the decomposition of animal and vegetable substances, placed there by nature or art; and which, through the agency of heat, moisture and air, are converted, after death, into the pabulum, or food, of the farmer's crops, and ultimately into animal food. Philosophers may mystify the subject—but after all, it is enough for the farmer to know, that these highly fertilizing matters, are nothing but DUNG, deprived of it gaseous properties, which by the bye are equally fertilizing, by the process of fermentation—they are organic matters, principally carbon and hydrogen, variously modified, according to circumstances, by the addition of oxygen, nitrogen, salts and earths. All the farmer has to do, to obtain this valuable food for his crops, is judiciously to deposite the raw material—the dung—in the soil, and the elements—nature—will readily perform the manufacturing process. But further to satisfy the scientific, or curious, we proceed to quote the remarks of some of the best modern investigators in the matter. We will begin with what we deem the *highest* authority, Thäer, the head of the Prussian School of Agriculture.

"Besides the four essential elements of its composition [oxygen, hydrogen, carbon and nitrogen,] humus also contains other substances in smaller quantities, viz. phosphoric and sulphuric acids, combined with some base, and also with earths and salts. Humus is the product of living matter, and the source of it. It affords food to organization, [i. e. to animals and vegetables.] Without it nothing material can have life. The greater the number of living creatures, the more humus is found; and the more the humus, the greater the supply of nourishment and life. Every organic being in life adds to itself the raw materials of nature, and forms humus, which increases as men, animals and plants increase in any portion of the earth. It is diminished by the process of vegetation, and wasted by being carried into the ocean by its waters, or it is carried into the atmosphere by the agency of the oxygen of the air, which converts it into gaseous matter."—(See Thäer, *Grundsatze der Rationellen Land wirthschaft*. Berlin, 1810. 4 vols. 4to.

We ought to have stated, that what is now more generally distinguished by the term humus, first attracted the philosophical investigations of Sprengel, who noticed it in exudations from the bark of the elm, and denominated it ulmin. We quote next from the Penny Cyclopædia, p. 221.

"This substance has been called *vegetable mould;* but as this is not a very distinct term, we shall, after Thäer and other eminent writers on agriculture, adopt the name of *humus* when speaking of it. *Humus* is a dark, unctuous, pliable substance, nearly uniform in its appearance. It is composed of oxygen, hydrogen, carbon, and nitrogen, which, with the exception of nitrogen, which is found only in some substances, are the elements of all animal and vegetable substances. It is the result of the slow decomposition of organic matter in the earth, and is found in the greatest abundance in rich garden mould, or old neglected dunghills. It varies somewhat in its qualities and composition, according to the substances from which it has been formed, and the circumstances attending their decay. It is the *product of organic power,* such as cannot be compounded *chemically.*"

We close our extracts with one from Raspail, who is distinguished as among the most indefatigable and intelligent chemists of the day. In controverting the theory of Sprengel, which it is not necessary here to particularize, he remarks as follows:

"What we have learnt from experiment of the insolubility of *humus,* and the origin of its apparent acidity, destroys all the authority of the theory which Sprengel and other authors had reared on a different supposition. The part which the *humus* has to act, seems to be merely to absorb a sufficiency of oxygen to furnish the herbaceous part of the plant with the carbonic acid which it is the office of the green substance to decompose for the nourishment of the growing textures; and possibly one day may confirm the idea that, by artificially supplying to the plant the carbonic acid which is necessary for its growth, the use of any kind of manure may be dispensed with(?) In fact, if a small plant be reared in pure sand, taking care to water it frequently, it will thrive and flower without difficulty. It cannot, in these circumstances, obtain the carbon of its texture, except from the small quantity of carbonic acid contained in the atmosphere. The roots, then, transmit to the plant only water and the salts of which it can be the vehicle; and the part which is exposed to the air is destined to absorb the gases which are necesssary for the formation of the textures."

We interrupt the extract here, to object to any hypothesis which dispenses with manure as *indispensable* to the fertility of the soil—to supplying the raw material, artificially, for vegetable mould, or *humus,* which one writer has termed *the cooked food of plants.* The plant in pure sand may grow and flower, by the aid of water and the carbonic acid in the atmosphere, but will it fructify, will it reward the labor of the husbandman who nurses it? But we resume our extracts from Raspail.

"Consequently it is not the leaves of the leguminous plants that absorb the gypsum which is dusted over them, but the roots, when the dew or rain has washed it into the soil; and hence the advantage which has been found of applying this powder a little before the dew comes on."

This hint comes in corroboration of what we have long believed, that gypsum benefits plants through the medium of their *roots,* and not of their *leaves—in* the soil, and not *above* it. Hence we have recommended that it be ploughed or harrowed in on its application in arable husbandry;—and hence, probably, its inefficiency, applied to the surface, in dry seasons, when there is not rain sufficient to carry it to the mouths of plants, or to decompose and fit it for those minute and delicate organs. We add another extract from Raspail, which cannot fail to interest the intelligent farmer.

"The use of quick-lime in the preparation of composts, has no other object than to supply the place of potash, which would be too dear, for the purpose of disorganizing the texture intended to form the manure and of disposing them, by carbonizing, for condensing and combining with the oxygen of the air, in order to furnish that part of the plant which is above ground with carbonic acid, which its leaves may elaborate. So also the ploughing in of the manure has no other effect but to preserve these textures in a state of moisture indispensable to their decomposition. Finally, all these perparations would be useless, if the soil in which these treasures of vegetation have been buried, were either not sufficiently porous to admit the passage of the air into it, or so much so as not to retain, to a certain degree, the air and water which the manure absorbs. Soils that are too clayey, and those that are too sandy, are, in fact, sterile; and, in order to fertilize them, it is necessary to mix them; but, as the textures of plants assimilate principally the carbonate of lime, the fertilizing of the soil is completed by enriching it with calcareous matter."†

Agricultural Society of New-Castle, Del.

At the quarterly meeting of this society in January, a committee appointed to "inquire into the causes of the scarcity and high prices of cattle, and to point out, if possible, the proper remedies by which the large farming and grazing interests of the state may augment their supplies, and maintain their reputation, among the graziers and feeders of the country," reported, among other causes, the following:

"1. The neglect of the farmers in the middle states in raising so small a portion of their young cattle except for the dairy, and universally adopting the culpable practice of selling them for veal, when from four to eight weeks old.

"2. The increasing demand for this description of stock, in the interior of the country, to the west and south-west, hitherto but partial grazing districts.

"3. The moneyed derangement of the country, within the last two years, which has lessened considerably the number of drovers, who from their heavy operations are necessarily dependant more or less on bank accommodations.

"4. The injurious practice which has for some time been operating against the graziers, compelling them to buy stock second and third handed, from companies and individuals, who go out and meet the cattle on their way to market, monopolize the trade, buy up, and retail out to farmers at an advance too great for their profits, or for the good of the public, as to their supply of beef at a reasonable price.

"To remedy in a great measure the first and second evils alluded to, the committee are of opinion that the farmers and graziers of the Atlantic states should all at the same time turn their attention to raising more of their own oxen and store cattle; believing it will pay them well to do so, especially by crossing our large native breeds with the fine imported Durham and Devon cattle of England, now so common amongst us.

"Of this the committee are more positive since visiting the celebrated New-Jersey cattle now in feeding by Mr. Edward Tonkins, of Gloucester county, which are three-fourths Durham from large native cows. Two of his large oxen will now nett, at seven and a half years old, 4,000 to 5 000 pounds of beef; and his three year old stock of the same breed, are now worth, to the butcher, about 120 dollars per head, though they have never been housed in winter, nor had more than a fair and ordinary keeping.

"To remedy the last evil alluded to, your committee unanimously recommend a meeting at an early day, of the farmers and graziers of this county, and the adjoining counties of Pennsylvania, for the purpose of forming an association, that shall, by experienced and competent agents, selected from among themselves, go into the cattle districts and buy in first hands on their account, and bring to stands established in this vicinity, such cattle as shall be ordered by the association; none of which shall be sold or bartered on the way, or disposed of by said agents until after their arrival at said stands, and not then, till sanctioned by the association. In this way alone, the committee believe, will the monopoly and high price of stock be met and regulated by the farmers and graziers themselves, a full supply always ensured to them of cattle of the best quality and at the lowest market price."

In the culture of Spring Wheat, in districts infested by the grain-worm, we feel justified in recommending, from the personal observations we have made, and from the information we have been able to obtain from others, that if the sowing is delayed till the 12th or 20th May, the later as we progress north, the crop will not be likely to be injured by the worm. Grain sown very early *may* also escape, as has been the case with some sown in April; but we want further evidence before we venture to recommend the practice. Should the early sown in any case escape uninjured, or late sown be injured, we shall take it as a favor to be notified of the fact. There were instances in this vicinity of the Italian being sown as late as June, and doing well.

Statistics of American Wool and Woollen Manufactures.

We have been presented with a small volume of 144 pages, duodec. giving a detailed account of the sheep and woollen manufactories in the northern states, and a partial account of the same in the other states; to which is added two valuable communications from Col. Jarvis, of Weathersfield, Vt. and of H. D. Grove, of Hoosick, in this state; the first giving the history of the introduction of the Spanish Merino sheep, and the writer's mode of treating them, and the latter a like history, and his mode of treating the Saxon Merino sheep. These two gentlemen were particularly engaged in the introduction of the sheep they describe. The statistics are compiled by G. Benton and S. F. Barry; and the work may be had at Little's.

The following is an exhibit of the number of sheep in each state, and of the woollen manufactories,—the number of pounds produced in each state, and its value, at 50½ cents, which seems to have been the average price for the last ten years.

	Sheep.	*Sets machinery.*	*Quantity. lbs.*	*Amount dollars.*
Maine, ...	622,619	24	2,023,512	1,021,873
Hew-Hampshire,	465,179	43	1,511,832	763,475
Vermont, ...	1,099,011	100	3.571,786	1,803,751
Massachusetts, ..	373,322	519	1,213,297	612,715
Rhode Island, ...	81,619	80	265,262	133,957
Connecticut, ...	265,169	184	829,299	410,313
New-York, ...	4,299,879	234	13,974,606	7,057,176
New-Jersey, ...	250,000	20	812,500	410,313
Pennsylvania, ..	1,714,640	123	5,572,580	2,814,158
Delaware, ...	150,000	20	487,500	246,187
Maryland, ...	275,000	15	893,750	451,343
Virginia, ...	1,000,000		3,250,000	1,641,250
Ohio, ...	1,711,200	30	5,561,400	2,808,500
Kentucky, ...	600,000		1,950,000	984,750
Total, ...	12,897,638	892	41,917,324	21,168,246

There was imported, in 1836, over and above our exports, 12,296,249 pounds of foreign wool, mostly of coarse quality, costing abroad less than eight cents per pound, and not subject, therefore, to duty.

Of this gross amount of wool, it is estimated that thirty-one millions of pounds were worked up in the manufactories, leaving twelve millions for family manufacture, three millions and a half pounds of which are supposed to be worked up in New-York, three in Pennsylvania, and two in Ohio.

The manufacturing establishments are employed in the following fabrics, viz: in broadcloths 344; cassimeres 178; sattinets 574; flannels 158; jeans, linseys, &c. 210: blankets, yarns and hats 24; carpets 61. Total sets of machinery 1,549.

Hoosick has 37,807 sheep, the greatest number of any town in this state; and Dutchess county 234,294, the greatest number of sheep of any county in the state.

The matter of this volume is interesting to the wool grower, manufacturer and political economist, and we recommend it to their notice.

In regard to Lime,

To be employed in agriculture, we find some new suggestions, and we think important ones, in a communication in the Farmer's Cabinet. They satisfactorily explain why ground limestone is not so good for land as effete lime, or lime which has lost its caustic quality, after being burnt, by the re-absorption of carbonic acid, and furnish useful hints for the application of lime in husbandry. The writer remarks on the first point—

"We cannot, by grinding, destroy the attraction of cohesion in limestone; there will be two or more atoms adhering. While this is the case it never will be converted into a super-carbonate. Destroy the attraction of cohesion, as the result shows is done by burning and slaking, and it will ultimately be converted into super-carbonate, when incorporated with the soil; is then soluble in water, and acts beneficially or injuriously, as the quantity is in accordance with the wants of the plant, or in excess, as other manures do."

Upon the application of lime the writer says:

"I have been in the practice of using lime for twenty-five years; there is little of the land that I occupy that has not had 200, and some 300 bushels per acre, applied in that time. In my first applications, it was slaked, spread and incorporated with the soil as soon as practicable from the kiln. But for more than twenty years I have spread but little that has not lain from three to twelve or more months, and when spread avoided all means that would incorporate it with the soil, that necessity did not urge for the accomplishment of other objects. The change was the fruit of a doubt of the ultimate utility of using lime to hasten the decomposition of vegetable matter contained in soil under regular cultivation, and that this questionable advantage was all I concei ved I had to place against the known and certain result, that by so applying it, it would be converted into carbonate at the expense of a material contained in the soil that there was, or in future would become, capable of supporting a vegetable; and that so far as it could be converted into a carbonate, before mixed with the soil, was clear gain; and I regard my experience as having fully sustained the conclusion."

---

† New System of Organic Chemistry, by F. V. Raspail. Henderson's translation. London: 1834: p. 172, &c.

To render Corn prolific.

It seems to be a great desideratum with farmers, to plant that variety of corn which will produce the most ears on a stock. This criterion of a good variety is deceptive, and passes for more than it is worth; and withal leads to a neglect of the main point which should engage the farmer's attention. It is not the *number of ears on a stock*, but the *number of bushels on an acre*, that should be the first aim of the grower; and this depends not so much on variety, as upon richness of the soil. Corn, like cattle, will produce according to the food which is consumed; and if this food is not in the soil, it matters little how many ears grow upon a stock, the product will be in the ratio of the food: if there are many ears, they will be comparatively small; if but few, comparative large, in proportion to the richness of the soil. An acre of good pasture will carry, say five sheep, through the season, and fit them for the butcher; but if the acre is made to carry ten sheep, they cannot thrive, and will not be fit for the butcher. And again—if the acre of pasture is poor and light, the five sheep put upon it will be stinted in food, and will not thrive. The gain in the sheep will be in proportion to the quantity of herbage they convert into mutton and wool. So with corn. The roots of this grain, like the sheep, range over the whole pasture of a field, gather the nutriment which it contains, and this is transmuted into grain and forage; the aggregate of which is not very dissimilar, whether the ears are three, two or one upon a stock, provided due regard is had in planting to the habits of the variety—so that the pasture be fed off clean, without being overstocked. We have frequently observed, that we have more ears upon a stock on the borders of our corn field, and where the intervals are large between the hills, or some of the stalks deficient, than we have in the centre of the field, or where the planting is close; and that the size of the ears, or the aggregate of the product, is always in proportion to the richness of the soil, and the excellence of its cultivation. The atmosphere undoubtedly contributes essentially to the food of the corn crop, where the surface of the soil is kept clean, open and permeable to it. The fermentation of long dung, in the soil, and the frequent use of the cultivator, tend to keep it in this favorable condition. There is no danger of gorging or injuring the corn crop with long manure, if it is spread and buried with the plough; nor are its fertilizing properties so much impaired, in using it for corn, potatoes and ruta baga, in this way, as they are by the system of *summer-yarding* it, so generally adopted in some counties lying west of Albany.

The remarks which we have made upon Indian corn, tending to show, that the product depends essentially upon the quantity of food which it finds in the soil for its subsistence, applies, with greater or less force, to all farm crops. The economy of management depends upon the judgment of the farmer in adapting the food, both as regards quality and quantity, to the wants of the particular crop. But let us not be misapprehended on one point: unfermented dung should not be used for the small grain or other crops which ripen at mid-summer—until it has been first prepared and fitted for them, by the autumn-ripening crops, as corn, potatoes, ruta baga, &c. These latter subsist principally upon the gaseous and volatile portions of the manure, which are first disengaged from the mass in the process of fermentation, and which are rather deleterious to the former, at the season when they are maturing their seeds.

Another criterion which some farmers consider as essential to a good variety, is smallness of cob. So far as this conduces to the early and perfect drying of the grain, it is entitled to weight, but no further. The objection to a large cob was answered by a gentleman, by asking the objector, whether it required most cloth to make him or his son a vest, pointing to a boy standing by his side? The circumference of a cob two inches in diameter, will contain double the quantity of grain that a cob of one inch in diamater will contain.

There is no doubt but the habits of corn change with change of climate; or in other words, that the dwarf northern varieties, when taken to the south, in a few years become acclimated, and assume the tall growth of the south. It is hence advisable, that where early maturity is desired, as it seems to be in our latitude, seed should be occasionally procured from the north. Another means of preserving the early ripening properties, is to select for seed the ears which ripen first. We have raised the Dutton corn, obtained from the green mountains of Vermont, for sixteen years; and yet, taking care to save for seed the earliest matured ears, we are not sensible that it ripens much, if any, later now than it did when we first planted it

---

Varieties of Indian Corn.

Dr. Brown, in an essay lately published in the Farmer's Cabinet, enumerates thirty-five varieties of Indian corn which he has in his cabinet. He divides them into five classes besides sub-classes. We give the names, as well for future reference, as matter of curiosity.

A. YELLOW CORN.

A. a. No. 1. Genuine gourd seed, of 24 rows; No. 2, of 22 rows; 3, of 20 rows; 4, of 18 rows; 5, of 16 rows; 6, of 14 rows; 7, of 12 rows.

A. b. No. 8. King Philip Indian corn, 8 rows.

A. c. No. 9. Sioux, or early flint, 12 rows; 10, Sioux of Pennsylvania, 12 rows; 11, Sioux and gourd seed mixed, 16 rows.

B. WHITE INDIAN CORN.

B. a. White flint. No. 12, genuine white flint, 12 rows, Virginia; 13, white flint, 10 rows; 14, early white flint.

B. b. White flour. No. 15, from Peru, 8 rows; 16, Pennsylvania, 8 rows, called Smith's early white; 17, New-Jersey, 8 rows; 18, New-York, 10 rows.

B. a. and *B. b.* No. 19, Mandan Indian corn, a mixture of 12 and 15.

B. c. No. 20, early sugar or sweet corn, 12 rows, grains shrunken.

C. HAEMETITE, OR BLOOD-RED INDIAN CORN.

No. 21. Common sized, 12 rows and red cob.
No. 22. Red cob with white grains.
No. 23. Reb cob with yellow grains.
No. 24. Red cob with brown grains.
No. 25. Red cob with white gourd seed.
No. 26. Red cob with gourd seed and yellow flint.
No. 27. White cob with yellow grain.
No. 28. Speckled red and yellow grains, on a white cob.
No. 29. The same on a red cob.
No. 30. Dwarf haemetite, commonly called Guinea corn.

D. BLUE CORN.

No. 31. Blue corn, 10 rows.
E. No. 32. The corn of Texas; each grain is inclosed in a pod or husk, and the ear in a husk.
No. 33. Corn found in the envelope of a Mexican mummy.
No. 34. Cobbett corn, grown in England.
No. 35. The famous Dutton corn.

We take the liberty of adding to the above list five other varieties in our possession, seemingly not embraced therein, viz:

1. Lake Superior corn, ears six inches, 12 rows, reddish brown color, said to be very early—from S. Robinson.
2. Squaw corn, 8 rows, blue grain, also early.
3. Corn from Trieste, on the Adriatic—ears six inches, and semi-conical, 12 and 14 rows, orange yellow.
4. Rice corn, ears four inches, grains like rice, and ears four inches long.
5. A yellow 12 rowed corn, from Vermont, ears considerably smaller than the Dutton.

Dr. Brown gives four criteria, the three first from Mr. Taylor, which should be regarded in selecting our seed corn, viz: 1, The most stalk; 2, the largest cob; 3, longest grain; and 4, early growth and quick culture. The reason for the first is, that a man can gather more grain, stalk, blade, top, shuck and cob, of large than he can of small stalks. This quality would not be so highly esteemed in the north; for tall large growing would be here late ripening corn; and besides, corn of this description will not bear planting so thick, and consequently will not yield so much per acre, as varieties of more diminutive growth. The large cob is preferred, because it gives the most corn. 3. The longest grain, because it decidedly settles the superiority of the farinaceous product. We dissent from this conclusion, and think the superiority in farinaceous product depends more upon *weight* than the *length of the kernel*. The Dutton, it will be seen by the communication of J. Wright, has weighed 69 lbs. the bushels. This has a short kernel; and yet we doubt if any long kerneled variety can be found to weigh so heavy, or to afford so much nutriment. The fourth requisite, early growth and quick culture, is a very important one to northern farmers.

New Agricultural Publications.—The *Practical Farmer* is the title of an agricultural paper which has been commenced at Mechanicsburgh, Pa. to be published monthly, on a sheet of 24 pages. The *Buckeye Plough-Boy*, on a 12mo. sheet, has been commenced at Cayahokia Falls, Ohio.

"Help one another."

This is an excellent every-day admonition, applicable to all ranks; and if acted upon with brotherly kindness, how much wretchedness and crime would it avert—what incalculable blessings would result to society. But it is not our present purpose to moralize upon the text generally, but merely to illustrate its beneficial tendency in its particular application to husbandry.

"*Help one another*" to do good, was the great maxim that prompted Sir John Sinclair, in his eminently successful labors to multiply the products of his native soil. He, more than any other man, effected the establishment of the British Board of Agriculture, and rendered it subservient to the noble purpose of multiplying the resources and comforts of his countrymen. He was principally instrumental in effecting the grand improvements in Scotch husbandry—improvements which, in sixty years, have quadrupled the products of her soil—which have converted the noisome moss into fields of luxuriant grain, reclaimed the barren heath, and covered her hills with herds and flocks. It is no stretch of fancy to suppose, that his individual efforts to help others, by his example in improvement, by enlightening the public mind in rural affairs, and in inciting to industrial emulation, and consequently to virtue, has annually added millions of wealth to the British empire. How many thousand individuals may at this day say he has bettered their condition! how many should bless his memory! How much more useful are the labors of such a man to the human family, than those of the chieftain in offensive war, who, at the head of armies, devastates towns and provinces, slaughters thousands, and reduces their widows and and offspring to penury and wretchedness.

The late Chancellor Livingston was another example of the great good which an individual may render to society, in rural matters, by acting upon the principle —"help one another." He was among the first and most active in efforts to improve our agriculture, by introducing new modes of culture, and valuable stock, and in illustrating their advantages by his practice and his writings. He has been eulogized as a statesman, a civilian and a patriot; and yet perhaps in no department was his usefulness more conspicuous, than in the departments of husbandry. His disposition to *help others* was a prominent trait in his character, and contributed very much, if we mistake not, to raise the agriculture of Dutchess to a pitch of excellence, excelling that of any other portion of the union. As an agricultural writer, he was not surpassed, in extent or usefulness, by any other citizen of the state; and his ample means were liberally employed in demonstrating the utility of what he recommended. Who will pretend to estimate the benefits, in dollars and cents, or in human happiness, which have been produced, by his individual exertions to improve our agriculture, to the state at large, and particularly within the sphere of his immediate influence.

We might cite innumerable examples, from the dead and the living, to show the immense benefits that have resulted to society from praise-worthy efforts to "*help one another*," of men engaged in rural affairs. The two we have cited will suffice to impress upon all, we trust, the importance of adopting the precept: and though we may not be able, individually, to do *much*, we may each do *something* to *help one another*; and these somethings, in the aggregate, will effect a great deal towards improving the moral and social condition of society. We see the benign influence of this precept happily illustrated in the conduct of the Friends towards each other; and it were well for society if these examples of brotherly kindness were more generally followed by other religious denominations. The duty rests upon all, and the recompense is alike attainable by all.

But we come now to the *improvement* of our subject—which is, to enforce the precept "*help one another*"—particularly upon our correspondents, and upon those who may *become* useful correspondents, and to ask them to communicate for our columns, whatever in their practice or knowledge may conduce to the benefit of our readers. If an individual, by cultivating a new kind of grain, root or pulse, or by any new mode of practice, adds ten per cent to ordinary profits, his discovery, or improvement, or new mode of practice, if made known, and adopted by his neighbors, will in like manner add ten per cent to the profits of each of them. Say, for instance, that a farmer, by discovering a means of preventing the ravages of the grain-worm, saves from destruction fifty bushels of his wheat crop, worth one dollar per bushel—the gain to him is fifty dollars. Now if this improvement is made known to twenty thousand farmers, as it would be in a short time if published in the Cultivator, and successfully adopted by them, it would add, in a single year, one million of dollars to the solid wealth of the country. Although the case we have hypothecated may be considered extravagant, and not likely to happen, yet it is but one of hundreds that may happen; and shows what great public advantage may grow out of a general disposition to promulgate useful information in husbandry, through the medium of agricultural journals.

On the Germinating of Seeds.

Seeds often fail to grow; and the seedsman is often faulted, for vending bad seeds, when the seeds are really good, and when the cause of their not growing is owing to the gardner or planter. To induce germination, moisture, atmospheric air, and a certain temperature, are indispensable; and it is also requisite that light be excluded from the seed, until the nutriment in the seed is exhausted, or until the root can draw nourishment from the soil. The first effect of the air, heat and moisture upon the seed is, to change its properties—to convert its starch into sugar—into a sort of milky pulp, the proper food of the embryo plant. If at this stage the seed becomes dry, its vitality is believed to be destroyed; but if these agents are permitted to exert their influence, the contents of the seed swell by degrees, and the first point of the future root having formed, breaks through the shell in a downward direction, and about the same time the first point of the future stem comes forth in an upward direction. The presence of air, heat and moisture are as indispensable to the growth of the plant, as they are to the germination of the seed.

Now it often happens, that when seeds are planted in fresh stirred ground, or when the soil is moist, they undergo the incipient process of fermentation, and the earth not being pressed upon them, and dry weather ensuing, the moisture is abstracted, and the seeds perish. Too much moisture is also often destructive to the vital principle of seeds—and others again are buried too deep to be vivified by solar and atmospheric influence. The first object in planting, therefore, should be, to place the seed just so far under the surface, and so to cover it with earth, as shall barely secure to it a constant supply of moisture. There are many seeds, as of the carrot, parsnip, orchard grass, &c. which, if not previously steeped, or the soil well pulverized and pressed upon them, fail to grow for want of moisture. Hence, in sowing orchard grass, it is found prudent to spread it upon a floor and sprinkle it with water, before it is sown, and to pass a roller over the ground after the seed is sown. And hence, in light garden mould, it is advisable to press, with the hoe or spade, the earth upon all light seeds after they are sown.

But we would draw the attention of the farmer, as well as of the gardner, to another mode of preventing failure and disappointment in the growth of certain seeds—and that is, by *sprouting* them before they are planted. This may be conveniently done with Indian corn, pumpkins, mangold wurtzel, beets, &c. on the farm, and with melons, cucumbers, beans, peppers, and a great number of other seeds which are assigned to the garden. The mode of doing it with the field seeds we have named is this; steep the seed twelve to twenty hours in water of a tepid or warm temperature—then take off the water, and leave them in a warm place, covered to exclude the light and prevent their drying, or in a dark cellar or room, and the radicles or roots will shoot in a few days, and may then be planted without injury. Being obliged to suspend our planting for four days, on account of rain, we found our seed, which had been previously steeped, and set by in a dark room, with radicles two or three inches long. It was planted with but little inconvenience, and did remarkably well. Mr. J. Nott sprouted a part of his corn last year, while a part of the seed was not sprouted—and what is worthy the particular notice of the farmer, he assures us that *the sprouted corn was not injured by the wire-worm, while the unsteeped seed was seriously injured*, although planted by the side of each other. Mr. Nott accounts for the difference in this way: The wire-worm attacks the chit, and feeds upon and destroys the germ; but the radicles having protruded, and not being to the taste of the worm, the insect attacked the solid part of the kernel, where its progress was too slow, and too remote from the germ, to retard its growth. Mr. Nott also sprouted his mangold wurtzel seed, and planted it so late as the 27th June. Almost every seed grew, and the crop might be called a good one early in September.

To sprout garden seeds, procure two sods, of equal size, say eighteen inches square; lay one down in the corner of the kitchen chimney, grass down; lay your seeds upon it, if small wrap them in a piece of brown paper; then place the other sod upon them, grass up—water well with warm water, and the seeds will sprout in twenty-four to forty-eight hours.

There is one manifest advantage in sprouting seeds—it tests their goodness, and shows whether they will or will not grow. A small quantity of seed corn, submitted to this test before planting, would in many instances prevent great loss to the farmer.

What quantity of Manure should be applied to the Acre?

The answer to this question involves many considerations which preclude a definitive reply—such as the condition of the land, the quality of the manure, and the kind of crop. Too much, as well as too little manure may be applied. What would be beneficial for an autumn-ripening, or hoed crop, would be prejudicial to a small grain, or summer-ripening crop, and more particularly if the manure is applied in an unfermented state, and be withal a waste of fertilizing matter. Twenty tons to the acre would not be too much for corn, potatoes, ruta baga, &c. if applied broadcast, and ploughed in; but if long manure, and applied in the drill, or hill, and a dry season should ensue, it might prove an injury; and if this quantity of long, or even short manure, were applied to the acre of small spring grain, it would probably cause a flush of straw, likely to be affected with rust, at the expense of the more valuable part—the grain. Dr. Coventry, late professor of agriculture in the University of Edinburgh, whose business and study it was to collect data, and make correct deductions in this and other agricultural matters, was of the opinion, that from four to five tons are yearly requisite to keep up the fertility of a soil, of the kind usually denominated spit, or tolerably rotted dung; and this supply he thinks a well managed farm may be made to produce. To show how this quantity may be obtained, and how it should be applied, we quote from Mr. Youatt, the writer of British Husbandry.

"According to that calculation," says our author, "it must be observed, that the course of crops is supposed to consist—on light soils, of the alternate plan of corn and green crops, [see New System of Husbandry,]—on clays, which do not admit of that system, that the holding contain a proportionate quantity of grass land; and that the quantity of manure should be supplied, not in small quantities annually, but in large ones, at intermediate distances of four, five and six years. Light soils, in the common course of husbandry, rarely require the application of putrescent manure oftener than once in four years, and in all cases where the clover is allowed to stand two seasons, it may be deferred without disadvantage for another year. Heavy soils may run six years without it, provided that the land be laid one year in fallow, and that there be sufficient meadow to be reckoned at least one crop in the course. It being, however, clearly understood, that—whether on light or heavy land—nothing but grain, seeds and live stock is to be sold off the farm, unless replaced with an equal portion of purchased dung; that the whole of the green crops, the haulm of pulse, and the straw of corn, be used in the most economical manner; and that some of the live stock be either soiled or fattened upon oil cake: which plan, if carefully pursued on good soils, with capital sufficient to secure an abundant working and fattening stock of cattle, ought, under fair management, to furnish an adequate supply of dung for any of the usual courses of culture."

"Having thus submitted to our readers all that occurs to us of importance on the subject of farm-yard manure, we shall here recapitulate a summary of the chief points which we deem particularly worthy of their consideration:

1. To bottom the farm-yard with furze, fern [in Yankee dialect brake,] dry haulm, [stubble, &c.] or any other loose refuse that takes the longest time to dissolve; and over that to bed it deep with straw.
2. To occasionally remove the cribs of store cattle to different parts of the straw yard, in order that their dung may be dropped, and their litter trodden, equally.
3. To spread the dung of other animals, when thrown into the yards, in equal layers over every part.
4. To remove the dung from the yard at least once, or oftener, during the winter, to the mixen.
5. To turn and mix all dung-hills, until the woody or fibrous texture of the matter contained in them, and the roots and seeds of weeds, be completely decomposed, and until they emit a foul putrid smell; by which time they reach their greatest degree of strength, and arrive at the state of spit-dung.
6. To keep the dung in an equal state of moisture, so as to prevent any portion of the heap from becoming fire-fanged. If the fermentation be too rapid, heavy watering will abate the heat; but it will afterwards revive with increased force, unless the heap be either trodden firmly down or covered with mould to exclude the air.
7. To ferment the dung, if to be laid upon arable land during the autumn, in a much less degree than that to be applied before a spring sowing.
8. To lay a larger quantity on cold and wet lands than on those of a lighter nature; because the former require to be corrected by the warmth of the dung, while, on dry, sandy, and gravelly soils, the application of too much dung is apt to burn up the plants. Stiff land will also be loosened by the undecayed fibres of long dung, which, although its putrefaction will thus be retarded, and its fertilizing power delayed, will yet ultimately afford nourishment.
9. To form composts with dung, or other animal and vegetable substances, and earth, for application to light soils.
10. To spread the manure upon the land, when carried to the field, with the least possible delay; and, if laid upon arable, to turn it immediately into the soil.
11. To preserve the drainage from stables and dung-hills in every possible way; and if not applied in a liquid state, to throw it again upon the mixen.
12. To try experiments, during a series of years, upon the same soils and crops, with equal quantities of dung, laid on fresh, and afterwards rotted; in order to ascertain the results of their application to the land. The whole quantity to be first weighed or measured, and then divided.

"The fermentation of farm-yard manure is, in fact, a subject of far greater importance than is generally imagined, for on a due estimation of its value mainly depends the individual success, as well as the national prosperity, of our agriculture. The experiments to which we point cannot, therefore, fail to come home to the interests of every man; they may be made without expense, and without any other trouble than the mere exercise of common observation and intelligence. Leaving, however, aside the discussion concerning the disputed worth of fresh or fermented—of long or short dung,—let the farmer sedulously bend his attention to the accumulation of the utmost quantity that it may be in his power to procure. The manner and the time of using it, in either state, must, however, be governed by circumstances which may not always be within his control; and every judicious husbandman will rather accommodate himself to the exigency of the case than adhere strictly to his own notions of what he conceives to be the best practice. In fine, whether favoring the one or the other side of the question, let him collect all he can; apply it carefully to his crops; and then, trusting to events,—"*let the land and the muck settle it.*"

On Stall Feeding Cattle.

In the management of our cattle, as in the management of our crops, much is lost for want of system and regularity. The stall feeding of neat cattle for the butcher is annually increasing, and promises to increase in interest as we progress in the culture of roots. There is probably a difference of one-third to one-half, in the profits of the business, whether it is well or badly managed. Under this view of its importance, we extract from the Farmer's Series, the following compendium of the management recommended in that work, although it be not precisely the season to apply the instructions which it conveys:

"The first point is the comfort of accommodation; for in whatever way they may be placed—whether under sheds or in close ox-houses,—they should have the security of perfect shelter from the weather, with a certain degree of warmth; that is to say—if in open hammels, the sheds should be broad, the roof low, and the floor well covered with an abundance of dry litter. We are, however, decidedly of opinion, that close walls will further the object more promptly; though we do not coincide in the idea that it will be promoted by too much heat; and we should therefore recommend a moderate degree of healthful ventilation. In these stalls litter is, indeed, very frequently dispensed with,—or else sand, or any rubbish, is substituted for straw; but there can be no doubt that the animals enjoy the comfort of a dry bed as well as their master, and the more they seek repose in it the better.

"The next, is strict regularity in the administration of food—both as regards the stated quantity, and the time of supplying it. The periods may be regulated as the feeder thinks proper; but, whenever adopted, should never be afterwards altered. The ox is a quiet animal, and those which are fed in the house soon acquire a precise knowledge of the exact hour at which it is usually given: if that be transgressed, or the customary quantity be not furnished, they become restless, but if the time and quantity be strictly adhered to, they remain tranquil until the next period arrives. If no disturbance takes place, they, indeed, then generally lie down to ruminate, and nothing will be found more to forward the process of fatting than this perfect quietude; wherefore, should not only the stalls be well bedded, but light should be very much excluded, the doors should be closed, all outward annoyance as far as possible prevented—and, in short, every means should be induced to promote complete rest, ease, and contentment.

"Some persons serve it out as often as five times a day; but the most prudent, and we think the better practice, is to give it as soon as possible after day light, at noon, and some time before sunset; which enables the animals to fill their bellies; and to have time sufficient for that quiet digestion which is interrupted by too frequent feeding. In stating that the quantity should be moderate, we however alluded merely to the not allowing the animal to have so much as will cloy him; he ought always to have as much as he can fairly eat with a relish, but the moment he begins to toss it about, it will be then evident that the keenness of his appetite is satisfied, and it should be instantly removed.

"The last is thorough cleanliness. The ox house should be opened before day light, and well cleaned, both by pail and broom, from every impurity. After the animals have been satisfied with food, whatever may remain should be immediately removed; and the cribs and mangers, should be carefully swept out, and washed, if necessary; water should then be given without limitation.* If their hides be then wisped, it visibly occasions a very pleasurable sensation: as they begin to fatten, the ancient coat falls off, and if this be accelerated by the curry-comb, the better appearance of the beast will well repay the trouble."

The atmosphere and the dews abound in the food of plants, in a gaseous or liquid form—with the "*cooked food*" of plants. The nutriment which they afford is principally available through the *roots* of plants, which are buried in the ground. In order that the food may reach these mouths, and contribute to the growth and perfection of the crop, the soil which covers them must be pervious to air and dew—it must be pulverized, the whole stratum or tilth—and the surface kept clean and mellow. If the latter is suffered to become baked and hardened, the air does not find admission, and the dews rest upon the surface, and are dissipated by the rays of the early sun, and are lost. Hence many grounds long in grass, become too close and compact, and lose at least a portion of these fertilizing properties of the atmosphere; and hence the utility of good ploughing and thorough tillage, and of keeping the surface, where there are hoed crops, mellow and clean. Curwen, the distinguished British agriculturist, grew field cabbages to the weight of 50 lbs. each, principally by keeping the horse and cultivator constantly at work among them, and thus feeding them with the cooked food of the atmosphere.

The New-York Farmer, the publication of which was suspended last fall, has been revived, and the editors give an assurance that it will continue to be published as formerly.

Potato Sugar.

We give the following as supplementary to the remarks in our last, on the conversion of potato starch into sugar. The first extract is from Saussure, and the other from Silliman's Journal of Jan. 1832. Taken together they afford an answer to the inquiries of our correspondent. The quantity of sulphuric acid employed does not seem to be material, according to Saussure.

"As starch boiled in water with sulphuric acid *and thereby changed into sugar*, increases in weight, without uniting with any sulphuric acid, or gas, or forming any gas, we are under the necessity of ascribing the change wholly to the fixation or solidification of water. Hence we must conclude that starch sugar is nothing else than a combination of water with starch in a solid state.—The sulphuric acid is not decomposed nor united with the starch as a constituent.

"A bushel of potatoes (see Silliman's Journal,) weighs about 60 lbs., and gives eight pounds of pure, fine dry starch. This amount of starch will make five pints of sugar, of the weight of nearly 12 lbs. to the gallon, equal to seven pounds and a half to the bushel of potatoes, or a little less than a pound of sugar to a pound of starch. The sugar is not so sweet as the Muscovado sugar, nor is it actually so sweet as its taste would indicate.

"This sugar may be used for all domestic purposes. It ferments with great liveliness and spirit, when made into beer, yielding a healthful and delicious beverage, and on distillation a fine cider-brandy flavored spirit.—It would, however, be most useful in making sweetmeats, and may be used upon the table instead of honey, for which it is a good substitute. It has already become a favorite with most people who are acquainted with it. Its taste is that of a delicious sweet, and as an article of diet is unquestionably more healthful, and less oppressive to the stomach, than any other sweet ever used."

State policy.—Maine has paid to her farmers more than $76,000 as a bounty upon wheat raised by them last year. Thus Maine, with a population of less than 400,000, gives 76,000 dollars, annually from her public treasury, directly in aid of agriculture. New-York, with a population five times as large as Maine, gives —*nothing!!* What WILL she give?

Correspondence Condensed, &c.

CUTTING UP CORN.

"*Baltimore, March* 1, 1838.

"While I have the pen in my hand, will you permit me to suggest, that you may confer an essential service on the southern portion of your subscribers, by some observations on the advantages of *cutting up the corn*, instead of *topping* it, as now generally practised here.

"H. M. F."

Thirty years ago we read a communication of John Nicholas, then we believe of Virginia, on the advantages of *cutting up*, instead of *topping*, Indian corn. These advantages appeared to us so palpable, that in the noviciate of our farming operations, nineteen years ago, we reduced it to practice; and although we have since adopted occasionally the topping system, by way of comparison, we have made it our general practice to *cut up* the crop ever since. We are convinced, from our long experience, that it possesses over the old mode of topping, the following advantages:

1. *It saves labor.* With proper implements, which every farm can furnish without expense, two smart men will cut up and stook two acres in a day. They cannot top more than one acre, and the tops are afterwards to be bound, stooked, and backed off the field, or left to be bleached till the corn is harvested, when they have lost half their value. A hill is gathered with a blow in cutting up; in topping, a cut must be made upon every stock.

2. *It adds to the grain crop.* We have satisfied ourselves, by careful experiments, that we gain six bushels of corn per acre, by cutting up, above what we obtain by topping our corn. And we account for it on the well known principles in vegetable physiology, that all the nutriment of plants must be elaborated, or prepared, in the leaves, and that this elaborated sap, or prepared food, *descends*—consequently, that when the leaves *above* the corn are taken off, by topping, the grain can gain no further nutriment, or accession of growth; and that when the crop is cut up, and stooked, the grain does continue to obtain nutriment, and accession of growth, for some days, from the descending, or elaborated sap, with which the succulent stems are abundantly charged. The leaves also continue their elaborating process for some days after the corn is cut.

3. *It augments the cattle fodder, and preserves its nutrient properties.* Cut and well stooked, neither the grain nor the forage are liable to be seriously injured by the weather, even if left in the field late. If topped, the tops must be exposed to the deteriorating influence of rains, wind and sun, till they are dry enough to bind, which diminishes their value. If cut up, the whole of the stocks are converted into forage. If topped, but a small part becomes useful. And if the butts are fed in the cattle yards, they imbibe additional fertilizing properties from the urine and liquids which abound there, and which are lost if there is no litter to absorb them. Hence,

In the fourth place, it gives more food to the crops, as well as to the cattle, by saving that which otherwise is often lost to the farm. And,

Finally, cutting up has this important advantage, at least in the north—it secures the crop, both grain and forage, from damage from early autumnal frosts—for after the grain is cut and stooked, it is not liable to injury from their occurrence. We may add, that the ground may be cleared two or three weeks earlier, for a winter crop, where it is desirable to sow in autumn.

From the general accounts we have of southern products in corn, we apprehend, that if fewer acres were planted, and these better manured, the labor would be less, and the products, or at least the profits, greater than they are at present—always excepting our friend Reybold, of Delaware, whose example is worthy of all commendation.

Spring Rye.—W. A. of Baltimore county, has our opinion, that spring rye is not worth his notice. We consider it the poorest crop a farmer can cultivate, and wherever it is seen growing, it betokens bad husbandry. Seed may be obtained from farmers at about a dollar a bushel.

"*A Young Farmer of Suffolk*" is informed that we have had no experience in *caponizing* fowls, and that we have no authorities which enable us to answer his queries upon this subject. The wood to be preferred for *smoking hams*, &c. is green hickory, next green hard maple—corn cobs are good with these woods, or alone. The colour of the hams indicates when they are sufficiently smoked—they should be a deep russet brown.

SUGAR BEET SEED.

Sherman M'Lean, writes us from Royalton, N. Y. as follows: "I raised last summer about 400 bushels sugar beets, and not having the necessary apparatus to manufacture sugar, I have concluded to set out an acre or more for seed, if the prospect of selling the seed will warrant the undertaking. Will it be safe for me to do so?" Yes, if contracts are early made with seedsmen before supplies are ordered from Europe. Great quantities of seed, we doubt not, will be wanted. Prepare the ground well, leave intervals of three feet between the plants—let either all the sprouts grow, or reduce them to one or two, and support the seed stocks by stakes or poles.

Swamp Muck.—J. Winch, jr. of East Roxbury, Vt. writes us that he has an exhausted farm, which he is in a hurry to improve; that he has a large quantity of barn-yard dung, and an inexhaustible supply of swamp-muck, and he asks how he can apply them both to the best advantage to the coming crop. If the muck resembles leaf mould, as we infer from his letter, that is, if it is reduced to a powder, and devoid of ligneous and woody matters, he may mix it with profit with his barn-yard dung, in equal parts, as early as possible, and apply both together; or he may apply the muck to his grounds for small grains, or as a top-dressing to his grass lands. The fermentation of the manure in the soil will induce a decomposition of the vegetable matter in the muck. We advise Mr. Winch to take time by the fore-top—and as soon as his cattle yards are cleared, as they ought to be, in the spring, to bed his yards from six to twelve inches with muck, as a source of fertility in 1839; and further, to grade his yards so that the liquids may not run off, but may be absorbed by the muck and litter to be deposited in them.

Hedges, &c.—G. G. Cotton, who writes us from Homer, Ill. will find his queries in regard to hedges answered in our late numbers. The indigenous crab and wild plum are probably the best plants he can employ, and the sod fence he proposes to build around his 400 acre prairie lot, will constitute an excellent protection for the young hedge. But if he begins, he must not look back—he must persevere, or his labor will be lost. A belt of forest wood, on the bleak side of his lot, would give beauty, shelter, and ultimately profit. We can say nothing, from personal knowledge, of the grain cutting machines, propelled by horse-power, not having seen such in operation.

SPREADING LIME.

Samuel Howard, of Perry, inquires if there is any mode of spreading lime, at the rate of twenty bushels an acre, other than that of doing it with the hands? A machine for scattering lime or gypsum, has been invented by Julius Hatch, of Great Bend, Pennsylvania, which our neighbor Bement has tried, and highly approves of. We think lime might be spread very well, at the rate of twenty bushels an acre, with a shovel, the man standing in, or at the tail of a cart containing it, and passing back and forward through the field.

Abel Curtis, of Laurel, Vt. wishes to know the cheapest means of raising water 100 to 150 feet. There is no *cheap* process of doing this. It can only be done by wind, water, steam, or animal power. Inquire at the Fair Mount Philadelphia Water Works.

Eli Stephenson, of Cabotsville, Mass. would advertise the public, that he has a fine three year old Short Horned Durham bull for sale.

Poll-evil.—John D. Rodney, of Lewis, Del. asks for directions to cure the poll-evil. Willich directs, that *to disperse the swelling*, the part be bathed with hot vinegar; and that if the hair be fretted off, and a discharge ooze through the skin, a fomentation, prepared with two parts of vinegar and one of spirits of wine, will be more proper. Should great inflammation ensue, bleed, apply poultices of bread, milk and elder flowers, and give physic. To *discuss tumors*, Mr. Clark recommends, that as soon as matter is preceived to fluctuate in the part affected, to introduce a large seton-needle, armed with a cord, at the upper end of the swelling, and bring it out under the lower part of it; from which orifice the pus will speedily discharge itself; and in a few weeks the wound will be perfectly healed, without leaving any scar or blemish, or the least trace of the disorder.

Foul in the foot.—L. B. of Wayne county asks how this should be treated? We give the answer from Lawrence on Cattle.

"In case of any fissures or cracks, attended with heat, wash them with strong lather, and apply oil of turpentine, or tar and brandy, and keep the feet dry until healed. When the claws appear distended and inflamed, and the cracks have an offensive discharge, scrape with a knife and cleanse the parts, dress with Egyptian honey and oil of turpentine, hot, butter of antimony, or any of the corrosive waters in common use. Should the foul be neglected until it becomes indurated or bony, extirpation with the knife will become necessary. But nothing is so necessary towards the cure, as keeping the parts perfectly clean and dry, for want of the resolution and care to do which effectually, many patients are never thoroughly cured.

"*Water for foul in the foot.*—Strong solution of blue vitriol and alum in water. If required very powerful, the acid of vitriol one ounce, corrosive sublimate four drams; or an ointment made from the above, mixed with honey and verdigris, applied on pledges of tow."

We can give no directions for the cure of the *hoof-ail*, as its symptoms are described. It seems to be a disease peculiar to our country. All we can do, is to suggest the preventives of keeping the animals dry, and well, and of giving them daily salt and roots. Can any of our correspondents cite a case of mortality among cattle which have had a daily allowance of roots and salt, and been protected from storms?

Rotation of Crops.—We have been desired, by a respectable correspondent, to give a list of a course of crops adapted to each of the leading divisions of our soils. The task of doing this, on a scale adapted to the circulation of the Cultivator, would be one of some difficulty. We shall offer some general remarks upon this subject in our essay upon The New Husbandry, and may afterwards enlarge upon it, so far as our personal knowledge will justify. In the mean time we would accept it as a particular favor, and the public would no doubt be greatly benefitted, if some gentleman in the south, or south-west, would furnish us with the courses adapted to those sections of our country.

"*A Young Farmer*" writes us from Salisbury for advice, whether he shall put his corn crop upon an old and very stiff-sodded meadow, not yet ploughed, or upon a two year old clover ley? We answer the latter. Let the long manure be taken out, spread, and ploughed under, and the ground well harrowed and planted, in as little time as practicable, from the 5th to the 15th of May. The old meadow may be turned over, and sown with oats, or oats or peas, this spring, and will be in good condition for long manure and corn next year. The fear is, that the vegetable matter of the tough sod will not decompose in time to feed the corn crop this year.

---

* According to an experiment stated by Sir John Sinclair, an old man was appointed to discover how often some cattle, consuming chaff and straw on a farm, went to the watering-trough in a short winter's day, and that he might not be confused in the execution of his orders, one particular bullock was pointed out for his report; according to which, *he drank eight times in the course of the day*, and the man was convinced that the rest of the cattle drank as often as the one fixed on. Now, twice a day is the most in which they generally get water; and they are not able, at one or two opportunities, to drink a sufficient quantity. Husb. of Scotland, p. 100.

SHEEP HUSBANDRY.

Samuel Manning, of Weston, Vt. will find most of his queries on this subject satisfactorily answered in our last number, in the extract from Daubenton, and the report of Mr. Randall to the State Society. In crossing breeds, with a view of multiplying good points, it is a general rule to take the male from the smaller, and the female from the larger breed. The markets are too fluctuating to quote, and prices vary greatly according to the purity of blood and beauty of the individual, often fifty per cent. The Hampshire among us are a variety of the South Down. We do not know of any Ayreshire cattle in the market. It is impracticable to obtain the statistical information our correspondent asks for. An excellent work on sheep, written by Chancellor Livingston, was published some years ago, at the expense of the state, and may be had of the Messrs. Skinners, booksellers, in this city.

To restore worn-out lands to fertility.—B. S. Patton, who dates at Clarksville, and who represents himself as being young in farming, solicits our advice. We possess no universal panacea; and can only apprise Mr. Patton, as we do all others like circumstanced, that exhausted lands can only be renovated by a course of management the reverse of that which has made them sterile; and that abundant instructions in the *modus operandi* of imparting, or perpetuating fertility, may be found in the columns of the Cultivator, and particularly in our March number. Men young in farming, as well as those young in life, must learn to depend for success, principally, on their individual efforts—on their mental as well as physical powers. Husbandry is a business in which a man may learn as long as he lives; and in which, the more the learns, the more he finds to learn.

Suckering Corn.—W. Gatwood, of Strasburgh, asks if the Dutton corn should be succored? We are not in the habit of succoring our corn. We have done it by way of experiment, without apparent improvement in the crop, and at a loss of time and forage. If the suckers are to be taken off, we should prefer cutting them at the surface to tearing them from the stock. The opinion has been given, and we think well sustained, that the succors perform an important office—that the pollen of their tassels impregnates the male blossoms after that of the main stocks, which developes earlier, has been blown or fallen off—so that, although they do not increase the ears, they increase the corn, by causing the ears to fill out to the extremity of the cob.

Beet Sugar.—We possess no data which enable us to answer satisfactorily the queries of J. Tomlinson, of Le Roy, upon this subject. We refer him to our March number, and give him the assurance, that he shall be enlightened further in the matter as soon as it is in our power to gratify him.

ITALIAN WHEAT.

The testimonies in favor of this grain multiply on our hands, although they were before amply sufficient to establish its high reputation.

Levi Hopkins, of Sennet, Cayuga, from six bushels of seed, sown on the 10th April last, on five acres of sandy land, threshed and cleaned up 202 bushels. The sample sent us is beautiful. Mr. H. had sixteen acres in winter wheat adjoining, which was much injured by rust, and produced less than the five acres of Italian.

A. B. Clark, of New-Hartford, Oneida, has raised the Italian wheat three years, twice successively upon the same field, without manure, (bad husbandry,) and obtained the first season twenty-five, and in the latter thirty bushels per acre. Mr. Clark also sowed three acres of Siberian on soil similar to that sown with Italian, and the product was twenty bushels to the acre. These facts are sent us by J. H. of Oneida, who adds, that "a great deal of the wheat lately taken to Albany, and called Italian, is not genuine."

Hams—A correspondent in New-Jersey asks how we keep hams in summer? We have employed various modes, but have not always been successful until we adopted that of covering the ham tight with crash or other coarse cloth, and then covering the cloth a with substantial coat of whitewash. This has always been effectual. Our correspondent notifies us of an error we committed in our directions for making the Knickerbocker pickle, in p. 187, vol. iv.: There should be 9 lbs. salt, and 3 oz. salt patre to *six* gallons of water.

"*A Subscriber*," who dates at New-York, is informed, that it would not be dealing fairly with our old patrons, to republish articles from our back volumes. He will find the information he desires in vols. 1, 2 and 3, which he can procure of our agents in his city.

Our Westboro' correspondent is informed, that "by 50 to 100 bushels of lime to the acre," we mean lime directly from the kiln—unslacked lime.

"Will you be so good as to let me know your opinion of the Indian buckwheat spoken so highly of by Gov. Hill, and to have a bushel forwarded to me, or direct me where it can be had? JOHN H. KING."

This Indian buckwheat we presume to be the same as is known under the names of Indian wheat, Polish buckwheat, and Siberian buckwheat, or properly, according to Loudon, *Beech* wheat, from its resemblance to beech mast, (*Poligonum Tartaricum.*) In some places it has the reputation of being superior to the common variety, but after cultivating it three seasons, we were not aware of its marked superiority. Its habit is rather dwarfish, blossoms green, and seed small. We like the flavor of the cooked flour better than that of common buckwheat. For a green crop, to be ploughed under, we think the old kind is to be preferred. It is out of our power, at present, to send the seed to Mr. K. not knowing where it can be procured. Von Thäer, who tried it repeatedly at the Prussian Agricultural School, found its produce quite insignificant.

Pumpkin seed oil.—N. Carter, of Painesville, O. writes us, that he has extracted five gallons of oil from ten bushels of pumpkin seeds; and he thinks if any plan can be devised to take off the hull, the business may be profitable. Mr. C. asks if there is any machine for effecting this operation? We do not know that there is.

W. Spencer, of Hadlyme, Ct. writes—"The last season I enlarged my turnip yard to half an acre, from which I got 443 bushels. I sowed the 7th July, in drills twenty inches apart one way, and about nine inches the other."

In reply to Mr. Spencer's queries,—what is the value of the ruta baga in comparison with potatoes for fattening animals? and what is the best way to keep them from heating and rotting? From comparative experiments it has been found, that the Swedish turnip is at least equal to the potato in fattening beef. To keep turnips from heating and rotting, they should be dry before they are housed or pitted—should not be stored in large masses—and should have ventilation. They are not liable to heat in cellars, which are capacious, and from which the rarified air can escape. Pits in the field should not exceed three feet in breadth, though they may be of any length. The roots should be raised above the surface in the form of a roof; and after the earth has been thrown upon them, holes should be made in the ridge, at intervals of a yard, to let off the heated air. Wisps of straw may be placed in these holes, that the impure air may escape.

Dextrine.—P. C. Spafford, of Westminster, will find his query in part answered, in regard to dextrine, in p. 78, last vol. of Cultivator.

"FAR WEST."

Within our recollection this term meant Utica, or Pittsburgh—but population has since been travelling west, till "far west" now at least means west of the Mississippi. We have a letter before us, inclosing five dollars for the Cultivator, dated "Far West, Missouri," fifteen hundred miles west of our longitude. We subjoin an extract, which will serve to give some idea of the vast extent of our unimproved territory, and of its inexhaustible recourses. "Far west," will soon mean, the Rocky Mountains—the valley of the Columbia River—the Pacific Ocean.

"The resources of the 'vast ocean of prairies' in the far west," says our correspondent, "are untold, unsung, unwritten, and if we should philosophize a little, or ask the geologist to search for something in these *everlasting fields*, it might bring forth some fresh blessing from the 'treasures hid in the sand.' Our weeds yield rosin; an account of which I have never seen in print. Some of the weeds taste like white pine, and some like pitch pine. When the prairies are on fire, this material greatly increases the flame and the smoke, so that, as the prophet said, 'the land thereof becomes like burning pitch.' When millions of pitchy prairies are rolling up their massy columns of smoke, our eastern friends should be informed, that we are making 'smoky days,' or the 'Indian summer.'

"The prairies have many things peculiar to themselves, which, if published, would be instructive and amusing. The soil, the grass, the flowers, the animals, the fowls, the insects, the climate and the winds, are different from the wilderness, or the cultivated countries of the east. Our bees are wild, but generally rich; and our paroquets may be said to be 'green birds with brass heads.' The robin of the northern states frequently stays in the Missouri bottoms during the winter months, but is never seen in the summer."

☞ Several communications on hand will receive attention in our next.

CORRESPONDENCE.

On the Construction of Barns.

Farmington, Con. February 9th, 1838.

Judge Buel,—Sir,—I am a subscriber to the Cultivator, and think much good will be effected by your labors; already within the circle of its influence is the spirit of inquiry aroused to the subject of improving our worn-out lands; and I think, too, our young men are turning their attention to their farms at home, with a view to render them more productive, rather than abandon them for the El Dorado of the west.

I was particularly gratified to notice your offer of a premium for the best plan of barn and stable adapted to common farmers. There is much and great need for improvement in this particular; the buildings in common use for the storing of hay and grain, and for the shelter of cattle, are any thing but convenient; indeed, convenience seems not to have been thought of in their origin. I have been waiting, in the expectation of seeing a plan presented by some of your correspondents, which would evidently be an improvement; one that might be a pattern barn for future builders; but as yet have none such. The two presented by Mr. Jewett and Mr. Johnson I think are objectionable.

The most expensive part of our buildings, and the least enduring, are the roofs; it is, therefore, a desideratum, to obtain the most space under a given amount of roof; the nearest approximation to that result, which we can obtain in our buildings, will probably be found in the square, with an elevation of the roof as far as is practicable with safety, and convenience of storing away fodder. With this principle for a guide, it has seemed to me that convenience and economy both would be obtained in a barn built on the following plan, viz: Length fifty-six feet; breadth forty-nine feet; heighth and length of posts twenty feet; space for floor through the centre; bays for hay and grain on each side of the floor; stables the whole width of the barn across each end, excepting a space for entrance, at the front end, which space may be a recess for storing the hay cart, or the doors may be placed flush with the outside of the building; the height of the stables to be barely sufficient for a man of ordinary height to stand erect, that all the space above may be obtained which is possible, and have the cattle stand comfortably; the loft over the floor to be so high as barely to admit the largest load under it, for the like reason; and if the floor is larger then necessary for threshing grain, the loft over the floor on the opposite end to the great doors, may be brought down to the level of the loft over the stables, which will leave room for the team hauling loads into the barn to pass under, and bring the front of the load close up to the loft.

The advantages of this plan are, saving the expense of mangers, and also one set of barn doors; greater convenience of feeding cattle; do. of stowing away hay and grain; a greater amount of space and more compact; a greater saving of waste room on and above the floor.

The slight draft of the plan I send you, has only one entrance and one set of barn doors; the cattle are to eat from the floor, consequently only requiring a manger pole, and boarded from them to the floor; the greatest distance to pass to convey food to the stock is eighteen feet from the barn floor; the three feet spaces are for a passway to convey food, and for the cattle to eat from. I think it preferable for cattle to eat from the floor, because it is the natural position; because you can better feed to them the sweepings and seed of the hay-mow; and because it is a saving of hay, in that the cattle will not so readily scatter it under their feet; the space can be more readily cleaned of the refuse than from a manger. The hay and grain can also, with much less labor, be deposited in two bays, the load standing in the centre, than one large one, on one side only. It is also a convenience to have two, one for grain and one for hay; no more waste space for the floor than is absolutely necessary. I have said thirteen feet width of floor; this is not too wide for convenience of threshing and covering of grain; nor is it too wide for the convenience of hauling in loads. The end opposite the entrance may be occupied by a low loft, which could not be done were there an entrance at each end of the floor. The team hauling in loads can be learned to back out the cart with the same facility they would pass out forward; and if they are taken from the load in the barn, they can pass out by the side of the load singly, or pass through the alley, by a door at the end. The space under the low loft will be the proper place for a fanning-mill, cutting box and tub for mixing straw and grain; and under this part of the floor may be placed the cellar for roots, so there will be no loss of room.

The objection to Mr. Jewett's plans, are needless expense in manger, or rather necessary in his arrangement of the stable, but needless in a different location; also in one set of barn doors, and double the length of plan that is needful; also, waste of space consequent on the length of plan, too long for width. The expense of inclosing the yard with buildings, is unnecessary; a yard should always have a southern or eastern exposure for the benefit of the sun.

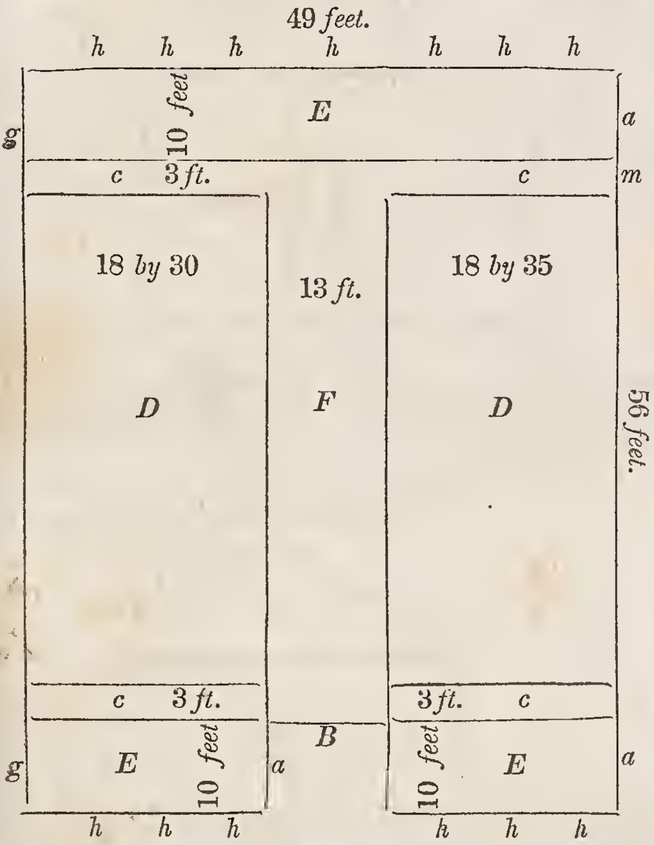
The objection to Mr. Johnson's plan are, that the bay is too large; it will be inconvenient storing away the hay, and a consequent loss of labor; and the remedy he proposes is to unload from the outside; but this is not to be done beyond a certain height, within the reach of the hand unloading, consequently not but a a partial remedy. A greater distance to supply the stock with food in the large barn; distance from floor thirty-six feet, in the adjoining stable or barn forty feet; larger proportion of roof for the same amount of space; large barn too long for width. The expense of sinks I should think unnecessary, (I suppose his object is to save the liquid from the cattle.) I think this is better saved by a liberal supply of litter, and changed daily as its becomes saturated.

The stanchions for securing cattle is a rough way, and perhaps more cattle may be stabled in the same space than in any other way; but they cannot lie as comfortably, and therefore I much prefer securing with a rope tied about the head.

I have thrown out these thoughts, sir, not in the belief that this plan is the best that can be devised, but in the hope that the attention of some one who has bestowed more thought on this subject than I have done, may favor us with his views through the Cultivator, and that the result may be a plan superior to any now in use, both as regards economy in space, utility and convenience.

One word as regards long or unfermented manure; let the advocates of fermented or rotted manure make a careful trial of equal quantities, and mark the result; my belief is, that at least one moiety of the fermented is lost in decomposition above ground.

Respectfully your obedient servant,
E. COWLES.



a, a, a, stable doors; *B,* barn door; *c, c, c, c,* spaces for feeding cattle, and in the place of mangers; *D, D,* bays for hay and grain; *E, E, E,* stables; *F,* barn floor; *g, g,* windows; *h, h, h, h, h, h, h, h, h, h, h, h, h,* ventilations for st[illegible]le and throwing out manure; *m,* door at the entrance of space or alley.

Smut in Wheat.

Judge Buel,—It has long been a desideratum to find a preventive of smut in the wheat crop; this year's experience has, in many instances, proven that *brining* and *liming*, as suggested in the "Cultivator," is not a certain preventive; at least it is certain that several farmers in this neighborhood, who prepared their seed wheat by soaking in brine, and adding as much lime as would adhere to it, found the crop smutty at harvest. It seems to be generally believed, that if wheat is *harrowed in* while it *rains* or *snows*, it will prove a smutty crop; experience has confirmed the fact in several cases this season, that have come to my knowledge. May not the secret after all be, that after duly prepared, the wheat be *dry* when sown and got in? Capt. Daniel Green, of this town, prepared wheat as above; about half of the seed after prepared, was kept till *quite dry*, before sown; the other moiety was sown while *still moist;* the latter when harvested was smutty, the other wholly free of it.

Your obdt. J. HATHAWAY.
Rome, January, 1838.

Remarks.—Notwithstanding these exceptions, the rule, that salt and lime are a preventive of smut, holds good, and can be attested to by thousands. We suspect either that the pickle was weak, the lime effete, or the steep not kept long enough upon the seed. Smut is a parasite. Its seeds adhere to the kernel. Salt and lime destroy their vitality. It is *possible,* that by sowing in wet weather, the salts may be so abstracted, as to render them ineffectual in killing the seed of the smut. But seed should be always harrowed in when neither rain nor snow are falling. The seed of the smut might have been in the soil, or in the bag in which the moist wheat was taken to the field; and if the former, the rain may have contributed to bring it in contact with some of the seed.—*Conductor.*

Poultry House.

Orange co. Va. Willow Grove, Jan. 18th, 1838.

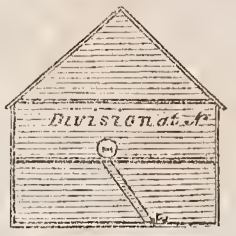
Dear Sir,—I have enclosed you a drawing of a poultry house, and as you justly remarked in your last number of vol. 4, of the Cultivator, although, superficially viewed, of comparative insignificance, it is certainly a branch of rural economy, which may be made to contribute largely to the economy and comfort of every family. And should you think it worth a place in your valuable paper, you may have it inserted.

Many of your subscribers in this section of country would be glad if you would have a drawing of the most approved ox yoke, with directions how to have it made and ironed on the best plan.

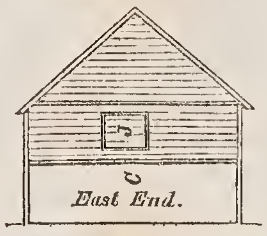
Respectfully yours, &c. W. D. CLARK.

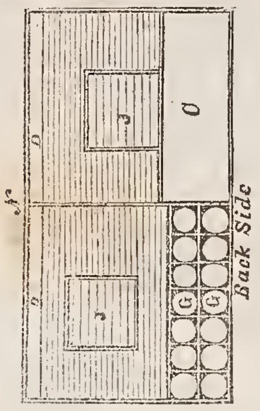
Explanation of the Cuts.

[Fig. No. 21.]



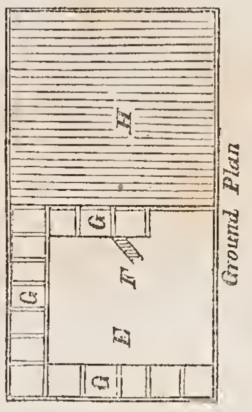
[Fig. No. 22.]



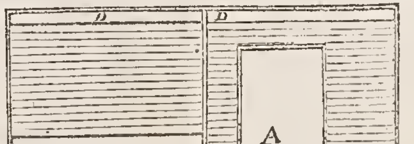


[Fig. No. 23.]

[Fig. No. 24.]



[Fig. No. 25.]



A, the door; B, the entrance for the fowls; C, C, C, the openings underneath the lattice or mitered floor where the fowls roost; D, six inch opening to admit air; E, the ground floor made of dirt, elevated above the surface one foot, with boxes for the poultry to lay and set in, or more properly a room for the poultry to set and lay in, to be increased with tiers as they may be required; F, steps for poultry to go to room to roost; G, G, G, G, G, G, boxes for nest; H, lattice or mitered floor for the litter from poultry to fall through, and room for the poultry to roost in; (i,) à round hole one foot in diamater, for fowls to pass to roost; J, J, J, lattice windows or blinds, three feet wide, three feet six inches deep. I have used the poultry house, of which the above drawing is a representation, for about eight years, and can testify that it is preferable to any known in this section of country, and many of my neighbors have thrown away their old houses, and have built after my plan. The roost for the fowls should be often renewed, and always of sassafras, as the smell of that wood is deleterious to the vermin on poultry. The floor in the setting room should be kept sprinkled with lime, and the litter from under the house taken away weekly.

Weight of Dutton Corn, in Indiana.

Respected Friend,—Having been desirous of ascertaining the best corn for the middle western states, I called last fall on J. M'Donald, of Allen county, Ia. to examine his Buel, or Dutton corn, and saw him shell and weigh a bushel. The weight was 69 pounds, and the product of an acre about 45 bushels. This is decidedly the heaviest grain that I have ever seen.

J. Buel. JUSTUS WRIGHT.
2d Mo. 26, 1838.

Sheep-Husbandry.

Weybridge, Vt. March, 1838.

Sir,—As much labor is bestowed in raising of wool within the circulation of your valuable paper, it is quite proper its patrons and wool-growers should now and then note a hint on sheep husbandry.

I do not expect in this communication to give general information to all interested in the subject, but if I have not learned some of the first rules of a good shepherd, it is not for the want of an opportunity.

I frequently hear it observed that sheep will degenerate where they have for a length of time been bred and kept on the same farm. To my satisfaction I have seen this proved otherwise.

My father was first in obtaining a flock of one of five hundred in this part of the state, and this flock and increase was summered on the same pastures successively forty-five years without shifting the ewes, and no sheep more robust were reared in this section of country; however, there was no breeding in-and-in, bucks were changed every year or two.

No animal is more nice in the selection of its food than sheep, and by giving them a sufficient choice, and free access to water throughout the year, the disorder generally attributed, and so fatal to sheep, called, "grub in the head," would rarely appear in our flocks.

Thin sheep in the month of July and August will take sudden colds, and viscid matter discharge at the nose within two hours after being exposed to rains or cold winds; in this phlegm the grub-fly deposits his eggs, at the same instant the sheep may be seen to cast up its head, and draw the larvae into the nostril, where it becomes a grub. Those in good condition will throw them out in the spring without any material damage. Sheep in good condition also may be killed by the grub, where full feed is not at all times allowed them to form the proper juices, which are secreted for their support; they will immediately gnaw into the brain, which terminates in death.—The shepherd that gives his flock sufficient forage, water, and exercise, will rarely be frequented by any raging distemper, except the scab and a foot rot, which spread by innoculation.

No animal needs water more than sheep; when fed on dry hay, without water, they do not receive a supply of the gastrick juices to promote the digestion in the stomach, soon loose their appetite, and are thrown into a fever.

Those in high condition will do tolerably well on snow, but to oblige ordinary and poor sheep to melt snow would be as proper as for a weakly person to resort to the same restorative to quench thirst. To confine them in small yards through the winter brings on a fever and general debility, which would be obviated by giving them exercise; one very essential point.

If they cannot otherwise be accommodated than in small yards, I would recommend a mound to be raised across the middle of it, so high that when they run over, those on the opposite side cannot be seen, which stimulates them to follow, one after another over this ridge,—when if the yard was level they would scarce move out of their tracks.

Respecting the rearing of lambs, I do fully agree with your correspondent, Mr. Daniel S. Curtis, in his communication in the 2d volume, 7th page.

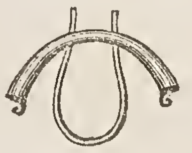
Yours truly, SOLOMON W. JEWETT.
J. Buel.

Yokes for Oxen.

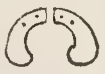
Juliustown, Burlington co, N. J. Jan. 9, 1838.

Sir,—In a retired place, I occasionally come across quotations from your valuable paper, and endeavored to get it; but it is not a month since I succeeded in obtaining the fourth volume of ten numbers by the mail. An article in the last number on "Working of Oxen," put me upon recommending through your paper, a mode of training and working them, which I have practised with unequivocal advantage for many years: it is, to give to each beast a separate yoke, with chains, or traces with a few links at the head, to hitch to a hook, two of which should be hung in an eye at each end of the yoke, as per figure 26.

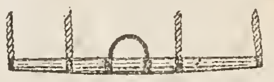
[Fig. No. 26.]



[Fig. No. 28.]



[Fig. No. 27.]



The chains, or traces, hitch to a whiffle-tree on the tongue, the same as for a pair of horses. No back-strap is necessary; and to loose the ox requires only to unhook the traces at the yoke, and throw them back on the tongue or cart.

For sustaining the tongue of the wagon or cart, figure 27, gives the form of a supporter, with four chains of four or five links, which attach to the forward hook on the ends of the yoke. The tongue, and the staple to steady it, must be *on the top* of this supporter, where a good iron plate for it to rest on, and to wear against the hold-back, will add strength and durability. Bits for the mouth, with straps to buckle behind the horns, and a coupling strap, are necessary; but *by no means* put blinds.

Oxen, bulls, or cows, trained to harness of the above description, may be directed in their course with lines, full as well as horses; singly to take a plough, or cart, for which there should be a separate yoke with tugs, and I am of opinion, *founded on experience,* will perform from ten to fifteen per cent more work, than in the old method of a double yoke. This gives them, when vicious, or worried a little, the power of quarrelling, by crowding or hauling; singly yoked, they are accommodated to the road, be it wide or narrow, sandy or irregular; they can straddle a log or hole without confinement to each other; walk freer, and consequently faster, and with less fatigue.

Cattle designed for work should be bridled early, and led about kindly; a small yoke should be put on them at a stage when they can be firmly managed by a rope attached to the bridle bit, which, with its straps, should be always strong; thus they may be rendered exceedingly tractable, much more so than horses are generally.

The *principal* use of oxen, (and bulls, which are stronger and hardier, and by early training are also made more peaceable,) in the heavy labors of agriculture and teaming, instead of horses, would result in very important advantages, both to the farmer and community at large. They should always be shod when worked on the road constantly, or in frosty weather. See figure 28.

I have heard that there are modes of bringing the draft on the head instead of the shoulders, practised in the Spanish provinces, the particulars of which I should gladly become acquainted with.

Your obt. sert. DAVID ALLINSON.

Hints to those who Write for Instruction.

That any information to be valuable, must be based upon experience, needs scarce an argument in its proof; nor is the assertion less in accordance with truth, that the value of any information must mainly depend upon the manner in which such information is conveyed. While facts are to be stated, it is essential that all the facts be brought forward. In treating of subjects connected with agriculture more especially is the above the case; the nature of the soil, the state of the climate, whether humid or dry, the average range of the thermometer, both perhaps in a great measure influenced by the remoteness from or proximity to the ocean or our great inland lakes, should be particularly noted. Thus would each be enabled to cull from the mass of facts presented by "The Cultivator," such as are best adapted to his individual case. How often do we meet with accounts of great crops, the beauty of a particular mode of culture, yet deficient in the essential points we have enumerated? To what possible advantage can they be applied, or rather of what evil may they not be productive, more especially among that class who, adopting agriculture late in life, either for profit or amusement, are deficient in that practical knowledge, which an early devotion to the subject can alone bestow.—On the other hand, had the writers been more particular in their narration, he had been ignorant indeed who had failed, since such failure must suppose an ignorance of the nature of his own soil, and other attendant circumstances, the knowledge of which, though more easily acquired, are by no means less necessary.

That the value of different articles for manure, depends upon the nature of the soil to which they may be applied, is a fact which, though readily conceded, appears to be but little attended to, at least if we may judge from practical essays on husbandry. As a proof of this, let us take the article of gypsum, or plaster as it is usually termed; no article can come more highly recommended, yet where can we find an account of the soils best adapted for its employment, the proper season for spreading the same, or the tests of its quality, (and no substance as a manure, differs more) whether it should be sown immediately after it is ground, or whether it will take no harm from remaining sometime before it is given to the earth. As an article of manure for certain localities its value can scarcely be estimated too highly, while we can imagine others where its employment, if not directly prejudicial, would at least be productive of no benefit; truly he would confer no small benefit on his country who would treat of this subject more at large.*

The article which appeared in a late number of "The Cultivator," on "new method of tillage," deserves serious consideration; it were the height of folly truly, to hold on the old, with no better reason than because it is old, and equally so to adopt, merely for its novelty, the new. There are some lands which require frequent ploughing, on these the rotation of crops is no doubt the proper system to be pursued, but are there not others which will pay better for being undisturbed? I trust the article I have alluded to, may elicit discussion on the subject, and thus give a new value to the pages of "The Cultivator." T.

Horn-ail.

Friend J. Buel,—Thinking the public might be benefitted by the following, I am induced to offer it for insertion in thy columns, viz: A cure for the hollow horn, or hollow head, in cattle. In cases of this disease, I have always resorted to the common practice of boring the horns, until one of my cows, without horns, was so diseased; in which case I took one half pint of good vinegar, two table-spoonsfuls of common salt, one tea-spoonful of pepper, and mixed them well together; the solution so compounded I poured into her ear, holding her head to one side, in order to keep her ear turned up, for the space of one or two minutes; then, after applying the same to the other ear, in the same manner, I turned her loose, and she is my milch cow this winter, it being five or six years since she was so diseased. Others of my neighbors have, in similar cases, resorted to the same method, always proving effectual. JOSEPH COPE.

E. Fairfield, Ohio, 1838.

Pennsylvania Barn, and Out-buildings.

Jesse Buel, Esq.—In No. 1, Vol. IV. of the Cultivator is an invitation for farming information, by the offer of premiums; this I was glad to see, not that I expected to obtain any of them, but that they would elicit information that would be valuable generally, and to me particularly, in planning farm buildings.

I possess a farm of two hundred and fifty acres, about half wood land, the other half cleared and tillable, on which, if all goes well, will be required additional buildings, nearly all that should be on a well improved farm. I have a central situation, with a very suitable slope to the south, such as is desirable and mostly sought by the farmers in this state. I have so far matured my plans as to make drawings, subject, nevertheless, to such improvements as I can make in them from what is yet to come in the Cultivator, and my further observation. With the view of contributing to the Cultivator my mite, (if a mite it be,) I have made the inclosed drawings; they are rough, but perhaps they may be understood.

Fig. 29, is ground plot of the whole concern, farm buildings, cattle yard, stack yard, rail-road, &c. on an extended scale. I purpose beginning with the barn, (Dutchman like; I live among them, and admire their barn economy.) A, barn with shed at one end and in front; B, wagon shed; C, store house for farm tools not in use; D, range of cattle sheds; E, poultry house; F, G, sheep and hog house; I, granary; K, boiling and smoke house, with winter and rainy weather work shop over it; L, dwelling; M, M, additional cattle sheds, or houses and yard in front; N, stack yard; R, R, rail-road through the whole line of buildings, (except the dwelling,) and a branch through the stack yard, when wanted and if the ground suits, (it does with me;) ·.·.·.·.·.·. dotted lines wagon roads for access to the back of all the buildings, and to the threshing floor in the barn.

[Fig. No. 29.]

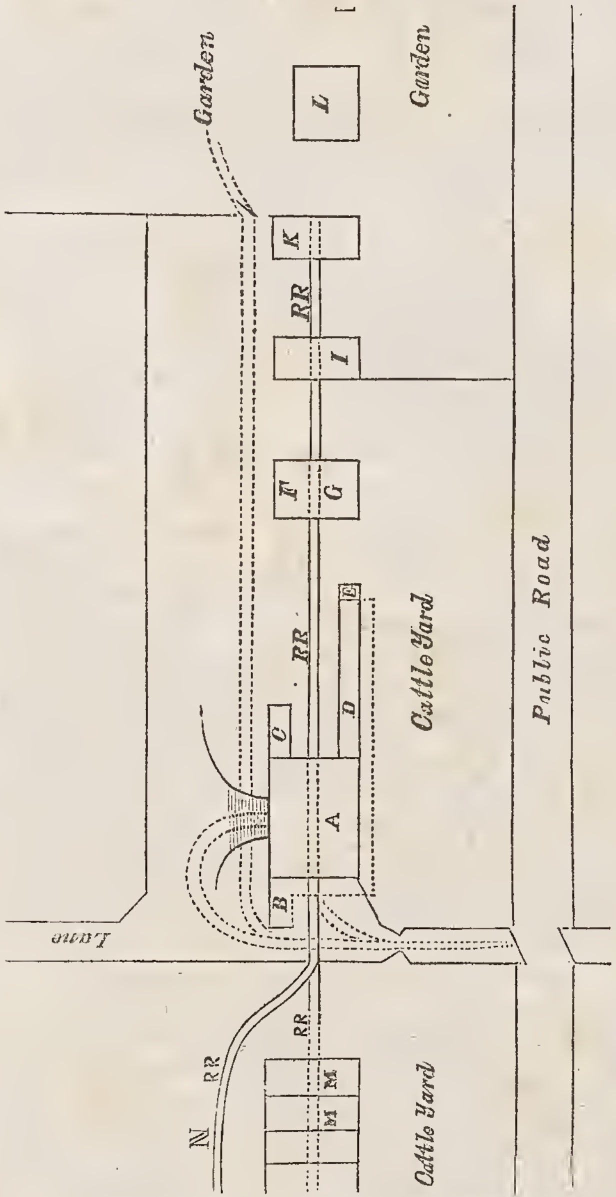


Fig. 30, ground story of stabling, &c. A, stables; A, A, other stables, or they may be dug out for cellars and bins for roots; B, bins and cellars extending under part of the entry within the dotted lines, to represent walls; C, entry with one door large enough to drive a wagon into to unload, or to load a wagon in for the market without risk of freezing in winter; D, doors; W, windows on the back side, with double sash to keep out the frost, and for light in the entry, also to fill bins; P, well with a pump; H, P, horsepower for working of threshing or any other kind of machinery above.

[Fig. No. 30.]

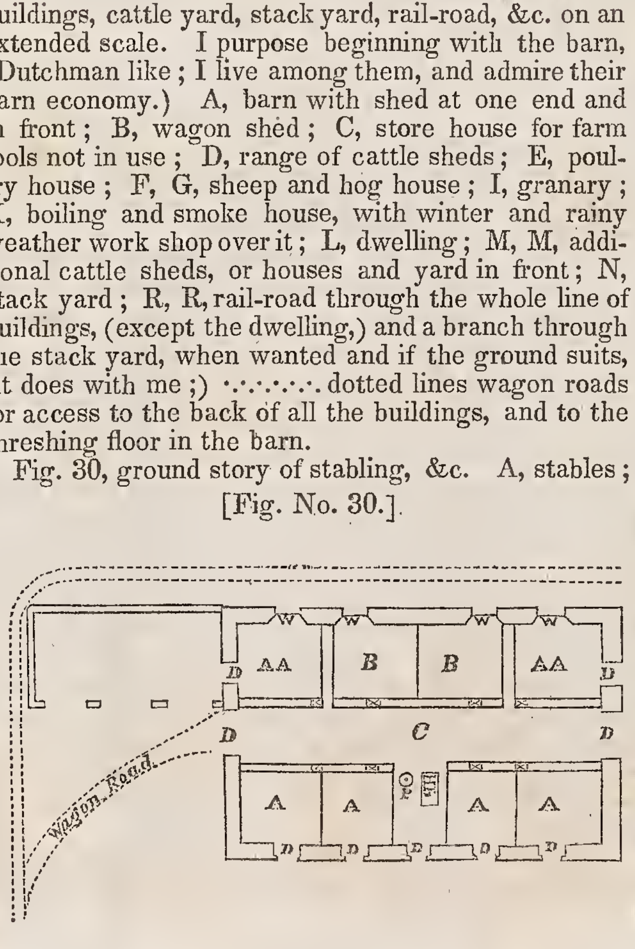

Fig. 31, represents the threshing floor and chaff room under it; access to the latter from the road back of the barn and under the bridge leading to the threshing floor.

[Fig. No. 31.]

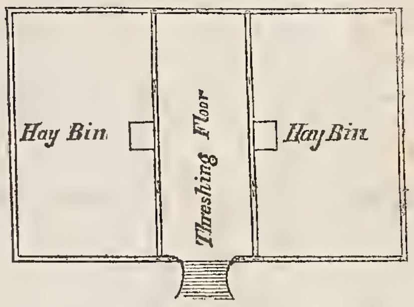

Fig. 32, elevation.

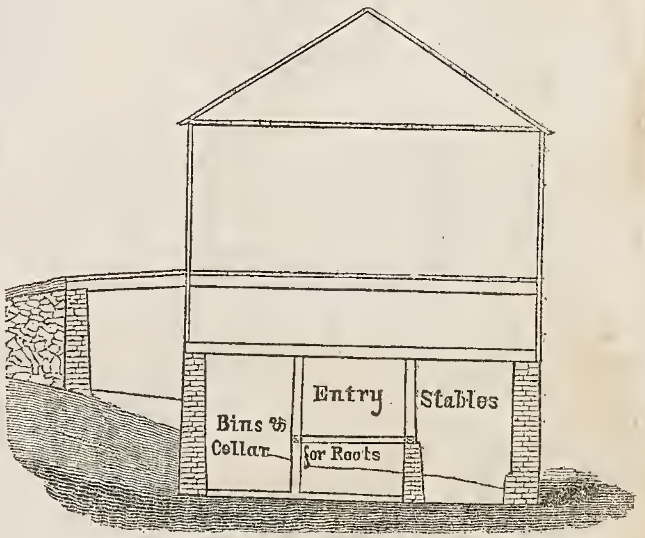
[Fig. No. 32.]



I have endeavored to improve on our German plan of the stable story, believing that the cost of the bridge, to the threshing floor, and the shed outside in front will be more than compensated by the room gained in the stable story for roots. The barn is all that I have undertaken to shew the inside of. All the buildings may be more or less convenient and expensive according to the proprietor's purse and inclination, (perhaps I may hereafter say more about some of them.)

As rail-roads are the order of the day, and as my ground is nearly level on a proper line for the front of the buildings, parallel with the public road, I have introduced one in my drawings through the centre of all the buildings, (except the dwelling,) to make transportation convenient from one to the other; the floor of the barn on which the car will run may be without rails, instead of which give the wheels of the car a face on the flang. I have contemplated constructing the car with a simple platform, so that we can place a steam box on it with the feed to be cooked in it, and take it on the rail-road to the boiling house, introduce a pipe from the boiler to cook by steam; when cooked, take it on the rail-way to any or all the buildings wherever they are to be fed; or, place on the car a light crib-work, (shelvings they are called with us,) for hay or straw from one place to another. One man can conveniently move on the rail-road half a ton weight. (Of the car more hereafter if desirable.)

From the accounts published in the Cultivator and others that I have read, root culture is extending, seemingly very profitable. My drawing embraces a cellar and bins that would hold about four thousand bushels, without obstructing the light, so placed that access can be had to them in freezing weather without danger; our climate at times is very cold and changeable, and we must provide against frost. My farm is about five miles from a good cash market for all my surplus; and if potatoes or other roots are to go to market in the winter, it would be very convenient to back the wagon to the bins to load and secure them out of the frost, to be ready for an early morning start.

Under the stable floor is a space between the front wall and the cellar wall, which may be filled with sand to absorb the urine of the horses or cattle. Some years since I called to see a relation, a good farmer, found him at his barn throwing sand into his stable, to replace what he had taken away. If my recollection is correct, (and I believe it is,) he said that the sand became good manure under the horses, and was well worth the trouble of renewing it at times; I do not recollect how often.

---

*Chaptal's remarks on this subject are not without merit, yet I am inclined to the belief that his opinion as to its universal applicability is carried too far, while the quantity recommended by him to the acre, is by one half, at least, too great.

I have found in my various operations, that to have things well done by subordinates, we must make preparations convenient to do them well, and that is a part of my study in planning buildings.

L. S. PENN.

New-Jersey Lands—Ruta Baga.

Long Branch, N. J. March 1*st*, 1838.

Dear Sir,—I would like to call the attention of some of your readers to this section of country. It is a very improving one, and susceptible of the highest state of cultivation; it has a water communication with New-York city; is contiguous to the Atlantic ocean; abounds in marl of excellent quality; and, in my opinion, there are few places in which land could be more easily enriched, and at a cheaper rate. Farms can be bought here as yet very reasonably; and I cordially recommend all who are in search of a desirable place of residence, to come and look at Shrewsbury, Monmouth co. N. J. ere they settle themselves.

For the first time, last season, I tried half an acre in ruta baga turnips; and though the crop bears no comparison to those crops noticed in the February number of the Cultivator, yet I am so well pleased with the result, that the ensuing season I expect to sow one and a half acres, and would put in still more, but for the want of manure.

Yours respectfully, E. H. VANUXEM.

Egyptian Wheat—Morus Multicaulus.

New-Haven, March 1*st*, 1838.

Dear Sir,—I observe in yours and other agricultural papers, the Siberian and the Italian varieties of the Triticum estivum, but nothing said of the Triticum compositum, the Egyptian wheat. Experiments have been made by Mr. Horick, which prove that the fly will not feed on this wheat, though it will feed on every other variety of the estivum. Has this wheat been cultivated to any extent in this country, to ascertain its value for agricultural purposes? In the Gardener's Dictionary, edited by Prof. Martin, it is said that this wheat has been cultivated in several counties in England; but the only objection to it is, that the summers are too cold for it. From this fact, it is concluded, that it will be well adapted to our country. I have a sufficient quantity of the seed of this wheat to make a trial, which, if it should succeed, will be communicated to you.

I have made a series of experiments with the Morus multicaulus since 1832, with a view of determining its specific character. The result of which is, that it is only a variety of the Morus alba, produced by a high state of cultivation. I planted the seeds obtained from the multicaulus in 1833; some of those plants thus obtained, appeared like the common white mulberry; indeed, perfectly so. I then took some multicaulus plants, and put them in very poor sandy land uncultivated. The plants became hardy, of slow growth, and formed wood so as to resist the winter. It appears to me, that the high cultivation has given to the multicaulus the properties of an annual, at least to a certain extent.

Yours with esteem, ELI IVES.

Spring Wheat—Barn Building.

Dear Sir:—Spring wheat, sowed the 15th of May on my farm the past season, has escaped the weevel and proved a good crop, certainly thirty bushels per acre. Sowed April 20th, much injured. Winter wheat, in consequence of the worm, or weevel, was almost a total failure.

Spring wheat seems to require a high situation, perhaps a northern or western aspect on elevated lands will do best. It suffers severely if drought should intervene between the time when it begins to cover the ground, and the time of blossom. I think the 15th of May full early here, if you would escape the weevel; in colder climates, perhaps the insects deposit their eggs later.

Barn-Buildings—That barn suits me best which admits of most scaffolding; my scaffolds are of scantlings laid about six inches apart, and sufficient extension to dry fifteen loads of hay at once. I find it difficult to cure early cut hay on the field,* and not sadly injure it in color and quality, but cured it must be before it is mowed away.

We spread our hay on the scaffolds when but partially cured, and open the doors and windows; if laid lightly on the scaffolds it will soon dry, and then pitch it down, it will invariably come out fine except injured on the field. These remarks are not expected to apply to hay grown on old meadows, of light produce, for it is expected that among those who read the Cultivator and are determined to go ahead, such meadows will be scarce. A second qualification of a good barn, is stables contiguous to the thrashing floor, for horses and cattle, for if those be remote much inconvenience is experienced in feeding. Yard-buildings: Upright racks four or six feet from the backside of the sheds, add to the warmth of the shed if well filled with straw or coarse fodder, and I judge the thrifty husbandman would seldom have them empty. But the greatest modern improvement in the yard, is the straw house surrounded with rack-sticks instead of siding, with projecting roofs to shelter the cattle; around this the cattle can feed without fear of being pent up in a corner. I think we have not carried out one ton of hay on our yards in the old way in two years; our cattle make very little waste and I think feel no pinching want, the cows go to grass in good condition, but I cannot come up to our neighbor Jones, of Jefferson, who sells 200 weight of butter from each cow; I have only made a little over 2,000 lbs. of butter and 400 lbs. of cheese this season from twelve cows, but my pasture is chiefly clover, which perhaps is not so good. With much respect,

Yours, &c., WM. WALKER.

Cobleskill, February 14th, 1838.

*If our correspondent will adopt our mode of *curing his hay in cock*, in the field, instead of curing it upon the scaffold, we are confident he will save labor, and have equally as good hay as he has now. The advantages of his mode are, that the hay, by being cured by the air, and not by the sun, retains more of the leaves and nutrient properties, and has a better color, and more aroma, than it would possess if cured in the sun. The same benefits are secured, and with far less labor, we think, by putting it into grass cocks, and curing it there, as soon as the mown grass is wilted in the swarth and freed from all its external moisture.—*Con. Cult.*

Utility of Agricultural Journals.

Upper Middletown, Ct. Feb. 28, 1838.

J. Buel, Esq.—Dear Sir,—I take the liberty of addressing you a few words in relation to your paper, the Cultivator. It has been, I believe, but a few years since agricultural papers have been successfully established in this country; and I may say, that the amount of information which the farming community are capable of obtaining from them, is really invaluable. The improvement which, by the means of the knowledge farmers gain from these papers, they are capable of making, is worth at least ten times the cost of them; and they can, if they choose, extend it much beyond this. A paper like the Cultivator, at one dollar per annum, is low, and few can find an excuse for not taking it, as they can have it delivered to them at an annual cost of $1.19, to any part of the union. Men do not consider their *interests* when they neglect to take such valuable works, at so inconsiderable cost; if they do, I know of no better way of describing their policy, than by the old adage of "penny-wise and pound-foolish." It is no doubt a fact, that agriculture is capable of great improvement, perhaps beyond what can now be expected. This improvement is to be gained by practice and experiment. But, if every man would practice and experiment, and keep the result to himself, there would be but little gained. It is, then, by the diffusion of each one's experience and knowledge, who has made himself acquainted with any important facts among the whole community, that this result is to be gained. And in what better or cheaper way can this knowledge be diffused, than by cheap periodicals? Evidently none. Therefore I say, that every man who conducts such a paper, and every one who, by subscribing, contributes his aid to support it, is a public benefactor.

It is the duty, and indirectly, the interest of every farmer, to try and extend the circulation of such agricultural periodicals. For if his interests depend on the improvement of the soil, it is evident, that the extention of knowledge is to produce this result, therefore it is his interest. Let every farmer then, try and induce his neighbor, who does not take such a paper, to take one; and by so doing, he will not only benefit himself and his neighbor, but his country and mankind.

Our farmers need only to possess information to value it. If they once see the importance of agricultural periodicals, they will be at once convinced of the value of such information. I believe the time will soon come, when they will see the advantage of it, from the increasing prosperity and thriftiness of their neighbors who, endeavor "to improve the mind as well as the soil." C. P. WILLIAMS.

On sowing grain early and feeding it off.

Schenectady, 6 *March*, 1838.

Dear Sir,—I have considered it important to sow summer wheat, oats, barley and peas, as early as the season will admit in the spring, that they should come forward, shade and protect the ground from becoming too dry by early drought, which often happens in May and June, sufficient to starve and stunt the plants, and render the crop light. If this method should be departed from, I think it should be by feeding the grain by cattle before it spindles up in the spring, with a view to prevent its ripening till autumn.

I believe the reason why our oats and other grains are lighter than the same are in England is, because our seasons are warmer, and ripen the grain too fast.

If I were to engage again in farming, I would sow wheat the 1st August, and when it became too large, feed it down by cattle. It would then acquire large roots, and in the spring would urge forward much larger plants than that sowed in September, and I suppose must produce much a heavier crop. I think this experiment worth a trial: for, I believe it is a fact, that winter wheat and rye will live for years, if fed and not permitted to spindle and seed. As the fly which deposites the egg of the grain-worm flourishes about the ordinary time that wheat is in blow, I would feed it again in April and May, or 1st June, that it should not spindle nor be in blow till about 1st August. It would then escape the fly, and ripen in September, as it does in England. The weather being then colder, it would ripen slower, and the grain be heavier, as it is in England.

It would also escape the injury called *rust*, which is a disease caused in June and July, by means of very wet and very warm weather, which feeds the wheat plants too fast, whereby they become gorged, and the little vessels injured and burst, making sores on the straw, called rust; like as men when they eat and drink too much of good things, become diseased thereby.

I would thus experiment with wheat, oats, &c. to avoid the fly. If the fly can be thus cheated, it would be for our profit, although the worm appears to be a new creation, to chastise us for disobedience.

A field of wheat of the present spring might be fenced into several parcels, and try experiments of feeding till 1st June, leaving a patch, &c.

Most respectfully, D. TOMLINSON.

Remarks.—Wheat and rye sown early in September, generally prosper better than that which is sown later, though the former is more exposed to the Hessian fly; and we have heard of instances of the good effects of sowing in August. It has been stated, with good reasons for its support, that the fly upon early sown wheat may be destroyed by feeding off the crop with sheep in autumn, who bite off that part of the grain in which the nit or maggot is deposited. The suggestion of feeding wheat in spring, to retard the development of the head till the fly of the grain-worm has disappeared, is certainly worthy of attention, and merits trial. It is an undoubted fact, that grain ripening in a cool season, or cool climate, is plumper and heavier than that which ripens in a hot season or hot climate. We have evidence, that Italian wheat sown late in May, did well the last summer.—*Cond. Cult.*

The Wheat Insect.

Doct. De Kay, of the Zoological department of our Geologists, in his report of December 3d, 1836, says: "During the past summer, our farmers, more particularly in the northern parts of the state, had occasion to mourn over their blighted harvest, and witness the devastation of their property, occasioned by an apparently insignificant insect, and to regret their ignorance of its peculiar habits, in order that they might be prepared to suggest some rational remedy for his depredations."

When the labors of this learned entomologist shall have made some progress, and been reported, I know no mode by which their utility will be aided so effectually, extensively and generally, as through the columns of the Cultivator.

This new enemy, the wheat insect, known chiefly by his deeds, has escaped the notice of farmers; accustomed to find the root of the evil from the *larvæ*, or maggot state of most insects, as of the hessian fly, cut-worm, &c., hence this has been called the grain-worm, grey-worm, &c.

Having been absent at the south two summers, I had only the worms to examine,—these were confined with the grain, but of which they never ate. The last summer I sought early for the insect, and before the appearance of the wheat ear, a species of fly began to cluster about the field, and as their numbers increased I secured several of them for future examination, by placing them in colorless spirits. I was happy in bestowing them upon Mr. Mather and his associate geologists, although too late in the season to supply my loss.

The want of my specimens prevents giving the minute specific description to be drawn from the length and situation of the antennæ, &c., and the still more important organs of destruction, its *pointed proboscis*, the *perfect insect*, and not its larvæ, being the cause of the evil. I can only describe them from recollection. About half the size of the horse-fly, of a brassy green color; body and legs light, shoulders large, and wings long, adapted to long flight; altogether different from the Hessian fly, whose compact body and short wings curtail its locomotive powers. This *fly*, and not *its young*, destroys the wheat; it pierces the grain with its proboscis, and sucks out the juice while in a fluid state, and at the same time deposits five or six orange colored young within the glume or husk of the grain; a layer is in all cases interposed between them and the kernel; a spot under and around these worms (which are deposited *viviparous* by the insect) is always observed discolored, as if the juice had oozed through the wounded grain, or had been deposited by the parent for their first nourishment.—These worms having acquired strength and *legs*, of which they were born destitute, emigrate to all parts of the plant and end their march at the root, where they remain until their transformation the next summer.

It may be worthy of remark, that after the hardening of the winter wheat, the flies remaining preyed in a similar manner upon the seeds of the quack grass, and deposit their young among its glumes. I am of opinion that nothing conclusive can be founded upon the experience of the last year's observation. Had not the harvest been delayed an unusual time, say two or three weeks, the winter wheat would have been too forward to be injured by the fly, in the same manner as the *late sown spring* wheat escaped their period of existence—that period being between the early and late blossoming of the wheat.

A speculative opinion founded on the above observations would imply, that should the winter wheat appear in great forwardness the ensuing spring, one might expect immunity from it? But if, from any cause, it should be rendered backward, the case will be hopeless, unless, by feeding it off, it should be delayed so as to blossom with the spring sowing. In my collection of the wheat-fly were two other species. They were not taken in their company. They differ in color, one having a conspicuous black spot near the extremity of the wing; the other having two or three colored bands across the wings. They are about the same size, and equally well armed for destruction; I know not on what they may be destined to prey; they too should be watched. C.

The Least of the bugs.

In an old number of the Genesee Farmer is an article headed "The least of the Bugs." The writer, G., appeals to the observation of his neighbors; alas, this, or his own future investigation, is his only resource for information, a system of entomology of our country remains a desideratum. I believe he is right in considering them clover bugs. Some strollers of this race occasionally deposit their eggs or larvæ on the newly formed ears of rye; the larvæ reaching the grain while yet in a fluid state, disturbs its juice, and prevents its regular organization; this grain not being circumscribed by a hard shell, like clover seed, shoots out into a spur called ergot.

I examined a sample of ergot, procured at or before harvest time, and found in every grain the track of an insect. Following its course I discovered either the larvæ or pupa, the last soon developed the perfect insect, which was a black, glossy and nearly hemispherical bug. Believing this insect was the cause of ergot I enclosed the larvæ, pupa and bugs in object glasses for microscopic observation, and sent them to the Lyceum of Natural History in New-York.

Unfortunately for my theory, the opinion of De Candolle had just been published, "that ergot was not a distempered grain, but a peculiar fungus."—The society, rather than decide against the opinion of the greatest botanist in Europe, I suppose, were forced into the belief that these insects were created to feed upon this peculiar fungus; strange profusion in nature indeed, that a solitary one should have been supplied with food sufficient for a battalion of them.

My specimens however were put in the museum of the society, and my memoir placed among its archives for the month of August, 1818, where G. may find them without further direction, and probably identify them as his "*least of the Bugs.*" My opportunities for examining clover seed have been very limited; sufficient however to see many grains perforated in the same manner as peas from which the bug had escaped. Should any one repeat my experiment, I would recommend the examination of the ergot to be made about harvest time; if too early, from the minuteness of the worm it may elude his vision, and if too late, its traces may be obliterated by the process of drying. I have not found it in the ergot of the shops. My opinion that this, which I consider as the clover bug, is the cause of ergot, has received further corroboration by observing, that a few solitary plants of rye, growing in a lot with some red clover, were loaded with ergot;—again, last summer, in a field of rye, a square rod, adjoining a pasture lot containing clover, produced more spurs than an acre at a distance in the same field. As a proof that insects do not confine their operations to one favorite plant, I have seen ergot on elymus, rye-grass; and the wheat-fly frequently deposits its young amongst the seeds of quack-grass.

From the above it results, that we are called to view this almost microscopic insect with some interest. Let us observe it a short time before sun-set—see, it raises a helmet which has concealed its head, poises its elytra or wing-covers, expands its white wings from their plated and folded position, beneath the wing-covers—its visible dimensions are increased full six-fold; it next takes an aerial execursion to join in a waltz-like circle with countless numbers of its species. But while we contemplate with wonder the perfection of its organization, our pride is humbled to think that nothing is wanted but increased numbers of these insects to destroy entirely, what they now do partially, the staple article, *clover-seed.*

I would further remark, that the aberration of this bug into the rye-field, according to medical opinion, furnishes a potent remedy called ergot, and by the same authority this ergot, when mixed largely in bread, occasions gangrene and death. This has been sufficiently published for the last half century to induce farmers to be careful to separate the ergot from grain before grinding. To recapitulate, *the least of the bugs* is not beneath the attention of the farmer, the physician, the naturalist, and of every one who can say with the Psalmist, "The works of the Lord are wonderful, sought out of all them that have pleasure therein."

Kinderhook, January 7th, 1838. C.

Otsego Leicester Sheep.

Mr. Buel,—Sir,—I most cheerfully comply with your request to furnish for the "Cultivator," some account of the large fat wethers I sold Mr. Kirkpatrick, which were exhibited by him, in the Centre Market, on the 22d of February last.

It has been the practice of our butchers, for several years past, to procure and exhibit, on the birth day of the illustrious Washington, the *best* beef, mutton, veal, and pork that could be procured; and in no instance, in my recollection, has the exhibition equailed the last. And it is no less wonderful than true, that the meats, now furnished in our markets, are, at least, one hundred per cent *better in quality and greater in quantity,* than they were ten years ago.

What stronger argument than this do we want, in favor of an improved state of farming and improvement in our stock?

Albany has long been famous for superior fat mutton. It is now about thirty years since the late Christopher Dunn, Esq. first introduced the famous New Leicester or Bakewell sheep into this region.—Wilkinson and others followed in his track.

About the same period, or a few years earlier, some of the large Teeswater cattle were first introduced in this vicinity by Messrs. Cox and Colden, of Rensselaer county. In 1821, M. Bullock, Esq. of this county, imported two Durham bulls; and in 1823, S. Van Rensselaer, Esq., imported, at great expense, one bull and two heifers of the "improved Durham short horned" cattle.

I give these spirited gentlemen the credit of laying the *foundation* for the improvement of our beef and mutton.

But the improvement of our animals, has been more manifest for the last eight or ten years. The miserable *rickety runts* which formerly disgraced our barn-yards, are giving place to the more square and stately Durham, or smooth, beautiful Devon—to the large lusty Leicester, or the broad, round bodied South Down.

In December last I made a visit to a friend, residing in Butternuts, Otsego county, who was kind enough to introduce me to some of the farmers in his vicinity.

It is about three years since I had visited that section, and I assure you, I was not only highly gratified, but very much surprised at the great improvement in their various stock of *grade* animals. The great improvement in *that part* of the country, I attribute to an Agricultural Society which has been established there some two or three years.

They had met a few evenings previous to my arrival, and when we met them in the course of our tour, I was much pleased to hear the observations made in the course of conversation to my friend—expressing the gratification and satisfaction they experienced at the last meeting of the society. And in a letter now before me, he says:—"Last night I gave my first agricultural *soire*, which was well attended, and I think, gave general satisfaction to all present. I think I never saw more a genuine interest and enjoyment in social intercourse than I witnessed last night. There was a constant interchange of opinions. My friends grouped together in knots of three and four, each engaged in discussing some subject of particular interest to them in their own business.—They were *all practical* farmers, who till the soil with their own hands."

To return to my *sheepish* story. In the course of our perambulations we visited the farms of Messrs. Adcook and Musson, which are situated on the hills, about two miles east of Gilbertsville, Butternuts, Otsego county.

In the yard of Mr. Daniel Adcook, I found the five fat wethers I sold to Mr. Kirkpatrick. Mr. A. had procured scales for the purpose of ascertaining their weights. I was present when they were weighed, and they averaged 203 lbs. One of them reached 230 lbs. Being satisfied they would make *larger* sheep then had ever been seen in our market, I purchased them on the spot.

They were slaughtered and exhibited in the centre market, on the 22d of February last, and their weight was as follows:

No. 1.	Two year	old	weather, ...	151 lbs.
2.	do	do	do	141
3.	Three	do	do	141
4.	do	do	do	161
5.	do	do	do	167

making an average of 152¼ lbs., or 38 lbs. per quarter. The largest saddle, I have been informed, was purchased and sent as a present to the Hon. Henry Clay.

Mr. Adcook, the breeder and feeder of these superior sheep, is an Englishman by birth, and numbers four score years—settled on the farm he now occupies, some thirty or forty years ago, when a wilderness. The mighty forest bowed to the stroke of his axe, and by dint of industry, economy and perseverance, he has secured a competency sufficient to satisfy any reasonable person.

Great credit is certainly due to Mr. Adcook for his long continued exertions and attention to the perfecting of his flock, both by selections and importations from England, of which the five wethers were a specimen. His flock now consists of about eighty head of choice animals, some of which, I presume, he would sell to breeders at fair prices.

His nephew, Mr. Musson, whose farm adjoins, has also a flock of very good sheep of the same breed.—I also found in the yards of these gentlemen some superior cattle, a cross of the Bakewell or Shakespeare breed with the Durham, and some beautiful calves from these cows by an high-bred "improved Durham short horned" bull, now the property of H. D. Grove Esq. of Hoosick, Rensselaer county.

From Mr. Adcook's we passed through the valley of the Butternut creek on to the West hills, about two miles, to the farm of Mr. Jackson, where we were shown some very good *grade* cattle and about sixty head of very good sheep. Mr. Jackson's sheep are more varied in character, (if I may be allowed the expression) than those of Mr. Adcook and Musson. Some partake of the Leicester, some of the Lincoln, some of the Cotswold. This, I presume, is in consequence of his having selected from various flocks.—Among them were some he had obtained of J. Wilkinson of Duanesburg, which could readily be selected by a person that was acquainted with his flock.

There was one thing about these gentlemen's premises, I cannot in justice to them, let pass without notice,—and that is the excellent arrangement of their buildings and sheds for the accommodation and protection of their cattle and sheep; (a consideration, I regret to say, too little regarded by most of our American farmers.) "Comfort and convenience" seems to be their motto.

Cattle and sheep do not claim all their attention, for I found my favorite Berkshire pigs in most of their pens. Ten and fifteen dollars is not an uncommon price there for pigs from eight to ten weeks old.

In the possession of Mr. Thomas Hollis, of Gilbertsville, I found ten very superior sows. Mr. Hollis has also some excellent *grade* sheep, a cross from a South Down buck, which he obtained of F. Rotch, Esq. of Louisville, who first introduced this valuable variety into that vicinity.

I have in a former communication spoken of Mr. Rotch's stock of Durham cattle and South Down sheep, and will now merely say, there has been great improvement in this stock since I saw them—evincing, in an eminent degree, what science, good judgment and attention may accomplish, when properly applied. CALEB N. BEMENT.

Three Hills' Farm, Albany, March 10th, 1838.

Top-Dressing Meadows.

Hamptonburgh, March 6th, 1838.

J. Buel, Esq.—Dear Sir,—I was so much pleased with the results of some experiments made last season and the season previous, in the top-dressing of grass or rather meadow grounds, that with your permission I will communicate them to the agricultural public. The information will not be new to many of your readers, and although others may remain sceptical, yet to all I would say try it, should it only be on one square rood. Soon after haying in the fall of '36 I had collected what manure could be scraped up (it having all been applied the preceding spring to our corn and potatoe crops) and carted on to the poorest part of one of our meadows, and spread at the rate of, say twenty loads, to the acre, and adjoining this, in the same meadow and the same kind of soil, which is a rather thin clay, I had spread thinly all the straw we could find in a perfectly dry state, and for this piece of folly was laughed at by some of my knowing neighbors, but while mowing this part of the meadow I invited some of them to witness the result, at which I was myself astonished; we could discover no difference where the manure was applied, and where the straw had been, but in both cases the quantity of grass was nearly double to that on either side where no manure or straw had been used. This experiment, pardon the frequent use of so ominous a word, was so successful, that I repeated it the past season, spreading all the straw we could muster immediately after haying, and in a few weeks the difference in the growth of the grass where the straw had been spread and that of the adjoining part of the meadow was so manifest that no one could doubt the utility of the practice—in the one case the grass started quick and grew rank and thick, and in the other, the growth at the end of two or three weeks was hardly perceptible, and I am told by a Long Island friend, that the crop will be more enhanced at the second mowing after the application than the first.—What is the rationale of the thing, I pretend not to know; I merely state the facts of the case. And yet, Mr. Editor, how common is it to see great heaps of straw about the barn or in the fields, left there to rot and become a nuisance, instead of adding, if properly applied, from 50 to 100 per cent to the crop.—And this species of manure is so much more easily, and cheaply applied; two loads being sufficient for an acre, whereas from twenty to twenty-five of barnyard manure would be required.

Another experiment, (pity some "experiments" of a more important character should not have resulted more favorably) I made last spring with ashes and plaster, has satisfied me of the great value of the former as a top-dressing for our meadows. I plastered a part of a ridge in a meadow, where the season before we had cut a middling crop of clover and timothy, and on the balance of the ridge I sowed ashes at the rate of twenty-five or thirty bushels to the acre. The crop on the whole ridge was improved, but the part that was ashed, turned off a swarth full one-third heavier than the other. The spot on which this last experiment was made, might perhaps have been ploughed to advantage, but there are numberless acres of what we call natural meadow, that cannot be ploughed without extensive ditching and under-draining, and while I fully coincide with you, Mr. Editor, in your views of the utility and great importance of this branch of agricultural improvement, it must be borne in mind, that comparatively few can afford, except by degrees, the expense which it would involve. All the surplus population of the Emerald Isle, in a quarter of a century or more, and at an expenditure of many millions, would hardly accomplish what would really be beneficial in our country. We must therefore adopt the best expedients within our reach, to add to the fertility and profits of our farms.

Permit me to say that the Dutton corn did not disappoint my best anticipations. Owing to the wet and backward spring last spring, we did not plant it until the last of May or first of June. The Dutton corn ripened to my satisfaction, while nearly one half the common eight rowed kind was soft—so that I am satisfied, that had we planted all of the former it would have been an advantage of more than twenty-five dollars. With much respect,

Yours, W. W. J.

Efficacy of Gypsum sown in Autumn.

Seneca-Falls, March 13th, 1838.

Jesse Buel,—Dear Sir,—I address you now simply to give you the result of an experiment which I made last year with gypsum. In October 1836, I sowed about six bushels per acre upon part of a field sowed to wheat early in September. The land was a mixture of sand, gravel and loam. It had laid several years in timothy. In the spring it was ploughed, and oats, corn and peas put in. Part of the field I applied no plaster to. The difference between that sowed with plaster and that on which no plaster was sowed, was quite one-half in favor of the former.—That which was plastered produced a vigorous growth of straw, while the heads of wheat were much longer and fuller than that which was not plastered. By sowing in the fall, the gypsum becomes, from the action of the fall and winter rains and snow, perfectly dissolved, forms a chemical union with the soil, and affords to the wheat plant its natural food. When sowed in quantities from five to six bushels per acre, the benefit is felt on the subsequent crop of grass.

From experience I am satisfied that gypsum ought to be applied on timothy and other grass meadows, in much greater quantities than are usually put on clover. Gypsum when sowed in large quantities on a clay soil, ameliorates it. Upon a few yards of stiff red clay I spread about half a bushel of plaster last spring; in the course of the summer the color of the soil changed to a dark brown, and the clay pulverized, lost its tenacity and became, when dry, almost as light as ashes. I agree with you in your opinion as to the manner in which plaster benefits different crops.—Of some plants, such as corn and clover, it constitutes the specific food. But others, such as timothy, wheat oats and barley, it benefits by its chemical action on the soil as well as by furnishing lime to those which require it. The wheat crop, as far as I have observed since the snow has left us, looks well.

Your obedient servant,

SAML. J. BAYARD.

REMARKS.

The suggestions in the preceding communication of Mr. Bayard are very important to the farmer. They go to render probable, what before was doubted, that gypsum may be advantageously applied to clays, if applied in larger quantities than usual; that it has a chemical action upon the soil, and is thus in directly and highly beneficial to crops upon which it is believed not to have any direct action. The improvements it suggest are, 1. To sow gypsum in the autumn, or early in the spring; and, 2, to sow it in larger quantities than usual upon clays. We sowed plaster upon our meadows in April, and upon two or three ridges the quantity was doubled, i. e., at the rate of two bushels the acre. The crop upon these ridges was nearly double what it was upon the rest of the field. Soil, clay loam. —*Cond. Cult.*

Smut in wheat.

J. Buel, Esq.—Dear Sir,—It seems that our wheat crop, as bread-stuff, in this country, is considered the most important; it is well known there are many evils befalling this grain, especially of late years.—Many inquiries has been made for warding off those evils. The smutting of this grain may be considered one of the greatest evils, although a remedy is found to allay the matter in some degree; yet the cultivator is not exempt from much trouble and anxiety, that is from the mode of liming, brining, &c. It is ascertained in my neighborhood, that the sowing of old wheat is a complete preventive; a neighbor having spared all his new wheat sowed of his old, observing the product to be perfectly clean from smut, when his neighbors and his former crop was more or less smutty; when this was fully discovered, they flocked to him for clean seed; inquiry was excited, and the circumstance of sowing the old grain was brought in question, and considered to be the only cause.

As we are small wheat growers in this section, but little has been said respecting the discovery. I have laid it up for a valuable truth. Mr. Editor, if you know nothing relative to this statement, I think you will cause it to be published in your paper, soliciting information; if correct, it must be a valuable acquisition to the public when generally known.

If the true cause of smut in wheat be an insect, the period of one year destroys them. If it be seed, the germinating powers must have perished. If buggy peas are kept over one season, there will be no live bugs found among them.

A small portion of fine salt sifted and raked into a bin of corn, or any grain whatever, immediately kills the insects or drives them off; can any quantity of salt sufficient to drive them away from the field be applied and not destroy the grain, at the proper season of their mischief? Respectfully,

ABEDNEGO ROBINSON.

Portsmouth, (N. H.) March 1, 1838.

REMARKS.

The modern opinion is, that smut is a parasitic plant, i. e. a plant which feeds and lives on the wheat plant, and Bauer, in the transactions of the Royal Society, says its seeds are so minute as to pass from the seed grain in the soil, with the ascending sap, to the ear of the grain, where it grows and produces smutty grain. Many of the salts, as marine salt, lime, vitriol, copperas, &c., are found to destroy the germinating principle of this seed, and the supposition is a rational one, that the smut seed loses its vital principle by being kept through one season, which we know to be the case with many seeds. And upon this hypothesis we account for the fact stated by Mr. Robinson. But even if old wheat is put into a bag which has contained smutty wheat, or is in other way brought in contact with smut seed, the infection will take, and the crop will be more or less affected.—*Cond. Cult.*

How to produce new varieties of Corn.

I selected last June from my early garden corn, sachatash kernels, sufficient to plant about thirty hills, continuing the rows a few hills with the original product of the cob. This corn was a bright yellow, and of tolerable size; the kernels picked out of the rows of the ear were also yellow, but not as bright a tinge as the original, but very well matured; those kernels must have originated from white sachatash, as I have never seen any other color of the sachatash, other than dark purple, which is used for coloring frequently; this corn was all planted at the same time, and the attention precisely the same. Its appearance was so uniform, no one acquainted with its growth would pretend to draw a line of distinction; it kept equal pace to maturing. The result of my experiment has far more than remunerated for the set out, and has successfully exceeded my expectations. In harvesting I found one uniform original appearance of the early garden, the sachatash differing only in softness. A few ears were boiled when in a proper state and found to be good sachatash. I have now a handsome little trace of this corn, no more mixed than common, where other varieties are planted neighbors to it; some ears being perfectly clear.

This statement infers, that different varieties of corn as to size, color, and period of maturing, may be chosen as fancy may lead, and planted aside or in the midst of sweet sachatash, which will receive a portion of sachatash in the ear, the product of which planted by itself, will be of the original in all the particulars, except it being soft, sweet sachatash. Mr. Editor, it will be my greatest pleasure to send you one ear of this experimented handsome corn, if any opportunity by sending it by water should occur, and hope it would be accepted. If any rare seed should be in your hands, intended for distribution at the time this may be received, I should think myself highly flattered in receiving a few seed, especially of such as promise a profit. A. ROBINSON.

Portsmouth, (N. H.) March 2d, 1838.

REMARKS.

The idea of improving our corn, by artificial crossing, is novel, yet perfectly philosophical; and we doubt not but in this way improved varieties may be obtained, or at least varieties combining the prolific qualities of one kind, with the early maturity of another. Although when corn is found mixed on the same ear, as white and yellow, the grain appears to resemble exclusively one or the other parent, that resembling the male must partake more or less of the peculiar properties of the female parent, and must of course constitute a new variety. Mr. Knight experimented with the pea, with wheat, and the strawberry, and produced by the artificial cross several esteemed varieties, several of which in consequence bear his name.—*Cond. Cult.*

Steeping and Tarring Seed Corn—Italian Wheat—Farm Accounts.

Sennett, March 8, 1838.

Judge Buel,—Dear Sir,—We planted about 12 acres of corn, most of it 8 rowed, some the large 12 rowed variety, common with us, and about 1 acre of the Dutton. All of it was soaked, tarred and plastered with great care, and planted the 12th to 15th of May. It came up remarkably even and thrifty, maintaining its superiority over all other fields in its vicinity, and has produced about 70 bushels per acre of excellent sound corn. The tarring and plastering, although not a perfect cure for the crows and wire worm, we are fully convinced is better than all other means hitherto employed, and for promoting the growth and ripening of the corn, so valuable, that accidental causes alone, will prevent me from using them hereafter. Their successful application requires much care, both in the preparing and planting, but when well done, will add one-fifth to the product, besides lessening the liability to be destroyed.

I sowed 6½ bushels of Italian spring wheat from Rome, on 5 acres of corn stubble in the best condition, the 15th April, and from it have received 202 bushels of excellent wheat, which I have sold for seed at 2 dollars per bushel. This all fell down, 3 weeks before it was cut, yet it did not rust in any degree, while winter wheat in the same field, was completely spoiled by it.

We sowed 2 acres of roots, ruta baga, carrots, and mangold wurtzel, and gathered about 600 bushels pr. acre from the turnips, but not as many from the carrots, and still less of the beets. We consider the turnip the most valuable for common culture, considering the relative labor, in raising and their value when raised, although the carrot is probably the most nutritious of the three.

The plan of keeping an account of the produce of different crops, and our operations, we have pursued the past year for the first time, and find it very useful; and on the whole have learned much, and we think laid the foundation for learning much more.

Yours very respectfully,

LEVI J. HOPKINS.

The Contrast.

The astonishing power of hereditary opinions, and of impressions received in early education, is attempted to be illustrated, by the following dialogue, supposed to have occurred in an evening conversation, between a farmer of the hereditary school, and his son, on the latter's return from school, where he had studied, with some interest, the principles of scientific farming.

LANSINGBURGH.

Father—Well, John, since you are becoming a scholar, I suppose you have quite outgrown the thoughts of being a farmer?

Son—No, father, the effect is quite the contrary. I have been paying considerable attention to the study of agriculture; and I assure you I have found it a most delightful subject.

Father—From the number of books and foolish newspapers, all about farming, you have brought home, you are in a fair way to run crazy and turn book farmer—why son I would sooner see you engaged in catching grasshoppers.

Son—Then, I suppose father, you consider farming as not susceptible of any improvements.

Father—Improvements, why what improvements do you want, John? Have not I been a farmer all the days of my life—and a good farmer? and were not my father and grandfather good farmers, brought up to it? and now I have been sending you to school, and on your return home, have commenced teaching me how to farm. No—no—John, that wont do—I am too old to begin to learn my trade anew from books, written by a parcel of lazy fellows, who never hoed a hill of corn in their lives.

Son—Then, I suppose you will plant corn on the same old field behind the barn where you have always planted it, and feed the same breed of long snouted, razor backed hogs.

Father—Yes, John, I have hoed corn in that old field many a day, by the side of your grandfather; and it is good enough for me, yet; and the pork of my old breed of hogs brought me over a hundred dollars last winter, and I have no doubt, they will bring me as much this winter coming; and if you intend to be a farmer, and are wise, you will follow my example, and not be led into the wild goose chase of book farming.

Son—Well, father, I am not disposed to question your claim to the title of a good farmer; and I am proud of being descended from ancestors of that most ancient and most honorable calling; but should I arrive at the honor of pursuing it on my own account, I shall feel additional pride in meriting the appellation of a book farmer. If I can succeed in raising sixty bushels of corn from an acre with the same, or less labor than it cost you to raise thirty; and if I can obtain a breed of hogs which are not more than half legs, ears and snout; and which will not, like Pharoah's lean kine, cost more than their value, I shall not consider that I disgrace my worthy ancestors by so doing.

Father—Ah, John, when you are of age you will of course act for yourself, and I hope, by that time, you will have more sense than to believe your sixty bushel stories, and hogs fatted upon moonshine. I have as good corn on the old family corn lot as any of my neighbors, and I think thirty bushels a pretty good crop. For my part, I dont think best to believe half the lies people tell.

Son—I have no wish, father, to believe lies; but I think I could give you most satisfactory proof that more than a hundred bushels of corn have been raised from an acre, in a great number of instances—

Father—Why John—I would not believe so foolish a story, if I told it myself. But I see I have sent you to school to make a fool of you. I hope, however, you will out grow it when you get more discretion.

Son—I hope, Sir, I shall improve in discretion, but I am very sure discretion will never influence me against being a book farmer.

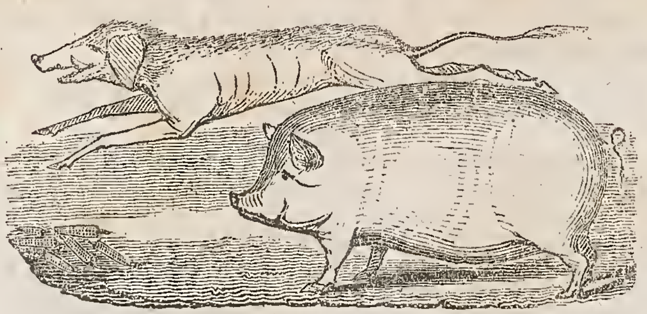
Father—A book farmer!—why my son, I am tired of such folly—have not I always been considered a good respectable farmer? Are not my crops always planted in season and tended and gathered in good order? What better can you do in farming, than to follow my example.

Son—Your example, father, as far as industry and attention to business go, are perfectly satisfactory, and I shall be proud to follow it. But you will excuse me when I tell you that book farming teaches me some improvements in the system of managing which I think are too important to be neglected. It teaches me that plants require food as well as animals; and that the ground which supplies that requires to be replenished from time to time with the means—it teaches me that if the manure which has been accumulating by the side of your barn ever since my remembrance, and is now rotting the covering, were spread upon your corn field, it would, at least, double your crop; that by changing crops the value of your land would be doubled. I have learned, by books, as well as by my own observation, that as great improvements may be made in the breeds of animals as in the choice and cultivation of vegetables, especially in the breed of hogs.

Father—Why, in the name of common sense, what improvement would you have in the breed of hogs?—My hogs last fall weighed from three to four hundred—do you want any thing better than that?

Son—Why, sir, the corn which fatted each of your hogs, to that weight, would have been abundantly sufficient for three of the Berkshire breed, of the same weights, and that which feeds your store hogs, with bodies as lank as grey hounds, and having as if you were breeding them for racing and leaping fences, would keep double the number of any of the improved breeds, with short legs and ears, so fat that their bellies would drag upon the ground.

By the way, father, let me show you a sketch I made at Hoosic falls, the other day—a fat hog, of the Berkshire breed, was turning to get at an ear of corn which lay between it and the fence, when a real racer, of your favorite breed, which was six or seven yards off, seeing the corn, and urged no doubt by his ever craving appetite, making what a Scotchman would call a *hop, step and leap*, jumped clean over him, and got the corn. [Fig. No. 33.]



Moneys received during the last month. Sums under five dollars not noticed.

THE CULTIVATOR:

A MONTHLY PUBLICATION, DEVOTED TO AGRICULTURE.

I KNOW OF NO PURSUIT IN WHICH MORE REAL AND IMPORTANT SERVICES CAN BE RENDERED TO ANY COUNTRY, THAN BY IMPROVING ITS AGRICULTURE.—*Wash.*

VOL. V. NO. 3, WASHINGTON-ST. ALBANY, N. Y. MAY, 1838. NO. 3.

Conducted by J. BUEL, of Albany.

TERMS.—ONE DOLLAR per annum, to be paid in advance. Subscriptions to commence with a volume.

Special Agents.—L. & R. HILL, Richmond, Va.; BELL & ENTWISLE, Alexandria, D. C.; GIDEON B. SMITH, Baltimore, Md.; JUDAH DOBSON, bookseller, and D. LANDREITH, seedsman, Philadelphia; ISRAEL POST, booksellers, 88 Bowery, ALEX. SMITH, seedsman, P. WAKEMAN, office of the American Institute, Broadway, N. York; E. M. HOVEY, Merchants's Row, Boston; ALEX. WALSH, Lansingburgh, and WM. THORBURN, Albany, gratuitous agents. For general list of agents see No. 12, vol. iv.

The Cultivator is subject to common newspaper postage.

☞ Price of the published volumes, 50 cents per vol. stitched—the four volumes bound together, $2.75—bounded in two volumes, $3—the four vols. bound each separate, $3.25.

THE CULTIVATOR.

TO IMPROVE THE SOIL AND THE MIND.

The New Husbandry.

IV. ALTERNATION OF CROPS.

Alternation of crops is an essential requisite in good farming, and forms a part of it wherever it is considered to have arrived at any degree of perfection. It is this which gave to Flemish husbandry a pre-eminence over that of every other country, long before the new system had obtained a footing in Great Britain. It is this which has principally converted the county of Norfolk, and other disticts in England, from the poorest and least productive, into the most wealthy and populous portions of that country. It is this alternating system which has contributed, in a great measure, to the astonishing recent improvements in the agriculture of Scotland; and it is this which constitutes the pioneer marks of improved husbandry in our own land.

In the preceding sections, we have suggested the importance and the modes of making our lands rich, and dry, and of subjecting them to good tillage. Let us now inquire under what method of management they are likely to make us the largest returns, without diminishing their intrinsic value.

It is palpable to every observing farmer, that the old mode of permanently dividing our grounds into meadow, plough and pasture lands—is a most wretched system of exhaustion, both to the land and its occupant. The tillage ground deteriorates, with the scanty manuring it gets, till it ceases to make a return for the expense of culture, or till it is thrown into old fields or commons. The meadow grasses run out, mosses and weeds come in, the soil becomes too compact and impervious for the ready admission of the great agents of vegetable decomposition and nutrition, and the free extension of the roots of the finer grasses;—and, as all is carried off, and little or nothing brought back, the soil is annually becoming poorer and less profitable. The pasture is the only portion of such a farm that is improving; and even in this bushes, brambles and noxious weeds are too often permitted to choke and destroy the better herbage.

It is equally apparent, that we cannot take two or more arable crops, of the same kind, from a field, in successive seasons, without a manifest falling off in the product. The reason of this may be found in an immutable law of nature, which has provided for each species of plants a specific food, suited to its organization and its wants. Thus some soils will not grow wheat, or other farm crops, although abounding in the common elements of fertility, and although they will make a profitable return in other farm crops,—in consequence of their being deficient in the specific food required for the perfection of the wheat, or other particular species of crop. One family, or species of plants, requires a different food from that which another family, or species, requires; and it seems to be another law of nature, that what is not essential to one family, or species, shall be left in the soil, or returned to it through the excretory organs of the growing crop. Of course, the specific food for any class, or species, continues to accumulate in the soil, the general fertility being kept up, till the return again to the field of this particular crop. Thus it is supposed to require ten or a dozen years for the specific food of flax, to accumulate sufficiently for a second crop, after one has been taken from a field. Even the specific food of clover becomes exhausted by a too frequent repetition of it in the same field: it being found necessary, in Norfolk husbandry, to substitute for it in every other course of crops, other grass seeds, so that this may not be repeated oftener than once in eight years. There are exceptions to the rules of practice which these laws inculcate. Some soils seem natural to wheat, others to oats, or grass; and successive crops of these are taken without apparent diminution of product. Yet it is better to regulate our practice by general laws, than by casual exceptions. In the cases noted as exceptions, there is probably so great an accumulation of the specific food of the particular crop, that it has not been *exhausted*, though it evidently must have been *diminished*. It is in accordance with the natural laws we have noticed, that the grasses in our meadows change; that the timber trees of the forest alternate—new species springing up as the old ones decay, or are cut down; and it is in accordance with these laws that the alternation of crops has been adopted in all good farming.

To simplify and render the subject more plain, the generality of tillage crops have been grouped into two classes, differing essentially in their character, culture, and exhausting influence upon the soil. These two classes are denominated *culmiferous* crops, and *leguminous* crops. The first is so named from *culm*, the stalk or stem of grains or grasses, usually jointed and hollow, and supporting the leaves and fructification. Our intention here is not to embrace the grasses. Culmiferous crops are termed robbers, or exhausters of the soil. This class includes wheat, barley, oats, rye, indian corn, tobacco, cotton, &c. These are particularly exhausting during the process of maturing their seeds. If cut green, or when in blossom, they are far less so. Leguminous crops, literally, are peas, beans, and other pulse; but here the class is intended to embrace all which are considered as ameliorating or enriching crops, as potatoes, turnips, carrots, beets, cabbages—and clover. These latter are not only less exhausting than the culmiferous class, as most of them do not mature their seeds, and all, on account of their broad system of leaves, draw more or less nourishment from the atmosphere, but they improve the condition of the soil, by dividing and loosening it, with their tap and bulbous roots. For these reasons they are called ameliorating or enriching crops; and as they generally receive manure, and drill culture, they are peculiarly adapted to enrich and fit the soil for the culmiferous class.

Good husbandry enjoins, that culmiferous and leguminous crops should alternate, or follow each other in succession, except when grass is made to intervene; and it matters little which crops are selected from the two classes. The good judgment of the farmer may here be exercised to determine which are likely to be to him the most advantageous. It may be proper to note two exceptions to this rule: Indian corn may, under certain contingencies, be made to precede or follow another grain crop to advantage, and oats may sometimes be profitably sown, as a fallow crop, to supersede a naked fallow, preparatory to a crop of wheat or rye. Some soils, it is true, are more favorable to one kind of crop than another; as for instance, calcareous clays and strong loams are better adapted to wheat, than silicious gravels and sands; while the latter are better fitted to carry Indian corn, turnips and clover, than clays. In other respects, such as the exhaustion of the ground, it is a matter of little interest with the farmer, what crops of each class are chosen to alternate with each other.

Farm stock seems necessarily to be embraced in the system of alternate husbandry. Cattle convert the bulky products of the farm, into meats, butter, cheese, &c. These concentrated products are carried to market at comparatively trifling expense. Cattle also furnish labor, and manufacture into manure the straw, stalks, and other offal and litter of the farm, necessary to keep up its fertility; for without manure, the soil will grow poor, and its products annually diminish. Manures, we repeat, are the main source of fertility to our soils, and the substantial food of our crops. Our supply of these will depend on the amount of stock we feed upon the farm; and the amount of stock we can keep profitably, will again depend upon the fertility of the soil, and the consequent abundance of its products. So that grain and grass husbandry, and cattle husbandry, are reciprocally and highly beneficial to each other. It is maintained, by practical men, that grounds under good tillage, will yield as much cattle food, in roots, straw, &c. as the same grounds would yield in grass, thus leaving the grain as extra profit.

The subject of clover, which we have classed with ameliorating crops, merits a further and distinct notice. We find that clover was cultivated at an early period by the Flemings, and constituted an important item in their excellent system of husbandry. Its introduction into Britian is of comparatively modern date. Forty years ago its culture may be said to have commenced in the United States; but its progress was slow till within the last few years; and even now, large portions of our country are practically ignorant of its improving and enriching qualities. Its benefits have been great wherever it has been introduced, accompanied with the use of gypsum; and the two combined have hitherto been the principal basis of good husbandry. But their benefits are capable of being far more widely extended. We consider the use of clover for cattle food, great as it is, but of secondary importance to the farmer—its most profitable use being to feed crops and ameliorate the soil. No green crop is so serviceable for the latter purposes; and we are satisfied from experience, that the practice of habitually sowing it with small grains, for these purposes, where it is not intended to stock with grass seeds, is an excellent one, on all grounds adapted to its growth. Upon this subject we quote as follows from Chaptal:

> "Artificial grass lands [constituting a part of the alternating system, and in contradistinction to natural and permanent grass lands] ought now to be considered as forming the basis of agriculture. These furnish fodder, the fodder supports cattle, and the cattle furnish manure, labor, and all the means necessary to a thorough system of cultivation."

V. ROOT CULTURE.

The advantage of root culture to the soil, in the alternating system, has already been briefly alluded to; but this culture possesses higher claims to our notice than the bare influence it has in ameliorating the soil: It constitutes otherwise a valuable source of fertility to the farm, and of profit to the farmer. It trebles the amount of cattle food, and doubles the quantity of manure. Potatoes constitute a great portion of the bread and meat of the Irish peasantry, feed their cows, fatten their pigs and poultry, and form an article of foreign commerce. The turnip has long been made an important crop in German husbandry. The beet has become so important in France, as to engage the attention of her scientific men, and of the government, in extending its culture. The field culture of the carrot has long been profitably pursued among the Flemings. And as it regards Great Britain, whose example in husbandry is deservedly held up for our imitation, her best writers on rural matters, and her best practical farmers, all concur in saying, that her pre-eminent success in modern husbandry, has been in a great measure owing to the introduction of turnips as a field crop in that island. We will here quote a passage from the New Edinburgh Encyclopædia, in corroboration of what we say:

> "The introduction of turnips into the husbandry of Britain, occasioned one of those revolutions in rural art which are constantly occurring among husbandmen, and, though the revolution came on with slow and gradual steps, yet it may now be viewed as completely and thoroughly established. Before the introduction of this root, it was impossible to cultivate light soils successfully, or to devise suitable rotations for cropping them with advantage. It was likewise a difficult task to support live stock through the winter and spring months; and as for feeding and preparing cattle and sheep for market, during these inclement seasons, the practice was hardly thought of, and still more rarely attempted, unless where a full stock of hay was provided, which only happened in a very few instances. The benefits derived from turnip husbandry are, therefore, of great magnitude: light soils are now cultivated with profit and facility; abundance of food is provided for man and beast; the earth is turned to its uses for which it is physically calculated; and, by being suitably cleaned with this preparatory crop, a bed is provided for grass seeds, wherein they flourish and prosper with greater vigor than after any other preparation."

Few of our readers are probably apprised of the fact, that English beef, so highly extolled, and of which John Bull so vauntingly boasts—and perhaps no people have better beef—is mostly winter fattened upon turnips and straw—very little hay being used. This will account for the high value which the turnip culture has obtained in Great Britain.

All the above named roots are well adapted to our soils and climate; and where their culture has been undertaken with spirit, and managed with judgment, success has been certain. The great objection to this culture has been, the labor which is required to secure these roots from the frosts of winter; and yet the labor and expense required for this purpose are perhaps no greater than we expend in securing our grain and forage—if they are as great. Where cellars are not at command, or not adequate, these roots may all be securely preserved in pits, in dry situations, due precaution being had to covering and ventilation. It is the novelty of the labor, rather than the amount, and a want of practical knowledge and confidence of success, which intimidates and deters us. We *do* save our potatoes, and we *can* save other roots in like manner. Assuming the average product of hay at a ton and a half to two tons per acre, and of beets and ruta baga at 600 bushels—and allowing a bushel and a half of the latter, (90 lbs.) to be equal, for farm stock, to twenty pounds of hay, an acre of the roots will go as far in the economy of feeding as nearly three acres of meadow, to say nothing of the tops, which will go far to pay the extra expense of cultivating the roots—while the ground in one case is ameliorated and improved, and in the other impoverished. These roots, besides, may be used as a substitute for grain, for working cattle, and for pigs. The three acres of grass gives less than 9,000 pounds to the manure yard, while the one acre of ruta baga, or beets, gives 36,000, or four times as much as three acres of grass land.

VI. SUBSTITUTION OF FALLOW CROPS FOR NAKED FALLOWS.

Fallowing is the mode of preparing land, generally green sward, by ploughing it a considerable time before it is ploughed for wheat and rye, to be sown in autumn. A naked fallow is such as receives no intermediate crop between the first ploughing and seeding for the main crop: a fallow crop is one that intervenes between these two processes. In England, fallows are generally broken up in autumn, receive repeated ploughings during the ensuing summer, and are sown in autumn, or cropped with turnips, and sown the third year with barley. In the United States, naked fallows are more often broken up in June or July, receive repeated ploughings, and are sown in September. For fallow crops, old swards are broken up in autumn, and clover lays in the spring; the first receives one or more ploughings in the spring, and immediately after the seeds which are to constitute the fallow crop. Clover lays receive the fallow crop upon the first furrow, or with but one ploughing. Naked fallows, in England, occupy the ground a year; and if they are sown with winter tares or rye, as they often are, to be fed off in the spring, they are termed bastard fallows. With us fallow grounds lay idle but part of a season.

There is no agricultural writer of note, and very few good farmers, who now contend for the propriety of naked fallows, except on stiff clays, or wet grounds, which can only be worked in the summer, and this for the purpose only of being able to clean such soils from root weeds. We subjoin two or three quotations in corroboration of this fact:

> "Fallowing was necessary as long as grains only, all of which exhaust the soil, were cultivated; during the intervals of tilling the fields, a variety of herbs grew on them, which offered food for animals, and the roots of which, buried in the soil by the plough, furnished a great part of the necessary manure. But at this day, when we have succeeded in establishing the cultivation of a great variety of roots, and artificial grasses, the system of fallowing can be no longer supported by the shadow of a good reason. The ease with which fodder may be cultivated, furnishes the means of supporting an increased number of animals; these in their turn supply manure and labor; and the farmer is no longer under the necessity of allowing his lands to be fallow."—*Chaptal.*
>
> "It is already acknowledged, that it is only upon wet soils, or, in other words, upon lands unfit for the turnip husbandry, that a plain summer fallow is necessary."—*New Edin. Ency.*
>
> "As there is only one good reason for fallowing, namely, to destroy weeds,—and as this can be done full as well by fallow crops, that is, by crops that require frequent hoeing and cleaning, during their growth, no fallows ought to be permitted in a good system of agriculture."—*T. Cooper.*

We have quoted in the last number of our fourth volume, the practical example of the late Chancellor Livingston, showing an increased profit, of nearly two hundred per cent, resulting from substituting fallow crops for naked fallows, besides an increase of cattle food, upon one hundred acres of arable land, of sixty-five tons, and the manure from sixty-five cattle, which this extra food would keep. In pages 88 and 104 of the same volume, we have given Greig and Beatson's systems of managing clay farms, in which naked fallows are dispensed with, and the profits doubled, by substituting fallow crops. These evidences might be greatly multiplied were it necessary; but we have so many examples and illustrations in every quarter of our country, that he who will may profit by his own observation and inquiry. The expense of the summer fallows may be saved, and a very valuable extra crop obtained, by the new mode of practice.

In regard to what are the best fallow crops? This will depend much upon the soil. Upon stiff clays, oats and peas are recommended, which although not cleansing crops, succeed well upon an undecomposed sod. Potatoes also answer well; and if they do not ripen early enough for winter grain, they prepare the ground remarkably well for spring wheat. Clays should be broken up in autumn, if intended for a fallow crop, that the frost may break down and pulverize the soil, and that the decomposition of the sod may commence earlier in the spring. The late John Lorrain, of Pennsylvania, who was an excellent practical farmer, as well as a gentleman of science, recommended, that in ploughing for grain, after a fallow crop, the furrow be supreficial, so as not to turn up the vegetable matter of the sod, but to leave it where the roots of the ensuing crop will most need it. Upon light soils, Indian corn, beans, peas, potatoes, turnips, or other roots, constitute good fallow crops, particularly preparatory to spring wheat and barley.

CONCLUSION.

We have gone over the ground we proposed to examine. We have endeavored to explain what we mean by the *New System of Husbandry*—to develope its principles, and to show WHY, and WHEREFORE, it is superior to the old or common system. We have, we think, demonstrated,—

1. That the *fertility* of the farm may be kept up, and augmented, by the manures it can be made to furnish;
2. That the *condition* of the farm may be much improved, by thorough draining;
3. That the *capacities* of the farm, can be fully developed only by good tillage;
4. That the *profits* of the farm, are materially augmented by alternating crops, and a system of mixed husbandry;
5. That the *cattle food* and *manures* of the farm, the main sources of fertility and profit, may be greatly increased by the cultivation of roots;
6. That the *labors* of the farm, may be economised, and its products further increased, by substituting fallow crops for naked fallows.

And finally, that were these several improvements generally introduced into our agricultural practice, they would render our farmers more independent, bring industry into better repute, and essentially promote the prosperity and happiness of all classes of society.

There is no doubt that most of our impoverished farms may, under the system of management we have been describing, and with the auxiliary and available aid of lime, marl, gypsum, swamp earth, ashes, &c. be progressively improved in fertility, and rendered productive and profitable. We have the strongest grounds for this belief. The like has been done in Great Britain, in the Netherlands, in Germany, in France. Worn-out lands have there been renovated and rendered very valuable. They have been so in the United States. They are now undergoing this improvement in the valley of the Hudson. The partial introduction of the New Husbandry, has, within a few years, doubled the surplus agricultural products of most of the counties between Albany and New-York; and yet the improvement has there been but begun.

The same management which our subject suggests for the renovation of old lands, will perpetuate the fertility of those which have been newly brought under culture. Although the soils of the great secondary formation of the west will not so soon become impoverished as those of primitive and transition formations; and though fertility may be more readily restored to them, when it has become exhausted—yet the same general laws govern in all. Deterioration will progress in all soils which are cropped, unless there is returned to them, in the form of manure, some equivalent for what is being constantly carried off.

The Conductor of the Cultivator will make it his business to continue to collect and publish practical instructions in rural affairs, and particularly in the improvements which it has been our object in this article to describe and recommend; in the performance of which, he respectfully invites the co-operation of practical farmers, in the various departments of husbandry, and in the different sections of our country.

Like Produces Like.

This is true, whether applied to animals or vegetables. It is a law of nature, and therefore immutable. If we would multiply a choice breed of animals, a valuable variety of plants, or an elegant flower, we must take care to breed from the individuals in greatest esteem. Although we may be considered trespassing upon hallowed ground, we will venture to remark, that these truths are not unworthy of consideration in matrimonial alliances. Constitutional defects, intellectual as well as physical, are often hereditary in man; and an alliance between two persons disposed to pulmonary affections, for instance, will almost certainly entail this class of diseases upon their offspring. We will not enlarge upon this branch of the subject, but apply our remarks more particularly to the improvement of farm stock and farm crops.

But we may be asked, in the outset, why, if our position be true, do not the seeds of our apples, pears, plums, &c. produce the same fruits as the parent tree? Because, we answer, these fruits, like animals, have two parents, a male and a female parent, which seldom belong to the same variety; and having a parent of two varieties, or breeds, it necessarily follows, that the offspring will not exactly resemble either, but partake, more or less, of the qualities of both. In most of our orchard and garden fruits, the sexual organs exist in the same flower; yet, from the varieties that are associated in the same ground, the female organ is liable to be impregnated with the pollen of the male organs of half a dozen other kinds. We have seen this strikingly illustrated in an experiment with the Siberian crab. Seeds of this fruit, which grew in an orchard of other apple trees, produced more than twenty new varieties, all partaking, in some measure, of the peculiar properties of the female parent, and yet none of them exactly resembling it. Yet there is no doubt but the seeds of the Siberian crab, or of any other variety of fruit, completely isolated, during the season of blooming, from all other trees of a like genus, would produce fruits resembling precisely the parent.

The practice of crossing breeds of animals has led to the great improvement of our farm stock. The new varieties of wheat, oats, barley, potatoes, Indian corn, &c. spring from th accidental crossing of two or more old varieties. They arrest the attention of some observing individual, are preserved, propagated, and come into repute for their prolific or other remarkable properties. We have had a field of China beans adulterated by growing in contiguity with the small white and pole beans. Although every bean planted the second year, was to appearance a pure China bean, in their growth many of them sent up runners, and when gathered, a fifth part of the crop was either white or pole beans, with the pollen of which latter the blossoms of the China beans of the preceding year had become impregnated. The artificial crossing of fruits was first practised by Knight about the beginning of the present century. He began with the pea, with wheat, and the strawberry, and has extended his experiments successfully to the apple, pear, peach, &c. The varieties of our Indian corn have been greatly multiplied by incidental fecundation; and we heard a naturalist insist, the other day, that all the varieties of this grain had sprung from two species. It is to this natural tendency to mixture, in the cabbage, turnip and radish families, and the heedlessness of American gardeners in seeding different species and varieties in the same ground, that foreign seeds of these plants are in higher repute than our own—the practice in Europe being to seed each kind by itself, remote from any other species of the family.

From the preceding considerations it must be apparent, that if a farmer would have good stock, he should breed from only the best individuals; and that if he has not good individuals he should procure them, at any reasonable price; that he should select and breed from those which are best adapted to his grounds and his business—whether it be for the market, for the dairy, for labor, or for wool.

That if he would have good crops, he must select his seed with care; and having obtained that which is good, he should keep it pure, by not permitting it to become fecundated and deteriorated by growing along side of inferior kinds, and by carefully preserving the best samples to breed from.

We beg to refer to the communication of Gideon B. Smith, for an illustration of the crossing process, in vegetables, which came to hand after this article was written.

Hints for the Orchard.

The slopes of hills are better for the apple orchard than flat or level surfaces—because the trees are not so liable to be injured by stagnant waters, upon the soil or subsoil. Upon a northern aspect, the fruit is not so liable to be injured by late vernal frosts, as upon a southern aspect—because, the blossoms are later in developing. A rich soil will give the largest and fairest fruit; a dry and warm one the richest, and bring it to the earliest maturity. The soil should be sufficiently rich to encourage a moderate growth, but not so rich as to stimulate the plant to premature exertion. It is better to have trees obtain a fair size before they fruit much, as fruit exhausts the nutriment of the plant, and prevents growth; and a precocious tree is generally a short lived one. The distance between apple trees should vary from 25 to 40 feet, according to the habits of the tree—whether spreading much or growing upright, the quality of the soil, and the other uses for which the ground is required. The distance may be lessened between the rows, by planting in the quincunx form, or planting the second row in the intervals between the trees in the first row—thus, $^{\,*\,*\,*}_{*\,*\,*\,*}$ Ground may be still further saved, by planting in clumps, of five trees, the centres of which to be sixty feet apart, and four trees at ten feet from the centre, on each side, thus, $*\overset{*}{\underset{*}{*}}*$. This leaves large intervals unobstructed by shade; the fruit is gathered more readily, and the trees mutually protect each other from the wind. Hogs and other farm stock are like men, in relishing acid as well as sweet apples. The nutrient properties of the apple are not diminished by the presence of the acid. The roots of a tree conform to the shape of the branches, and generally extend under, as the branches do horizontally over the ground.

Children belong to the Republic.

Thus taught the Spartans, and thus we should teach. As the twig is bent, so will the tree incline. If we sow tares, we cannot expect to reap wheat. Children are the materials—the wood, brick and mortar, if we may so express ourselves—which are to compose our temple of freedom; and if these materials are bad, or unsound, dilapidation will ensue, and the beautiful fabric will ere long fall to the ground. If children are brought up in idleness, they are too often useless to themselves, and become a tax upon society. If they are not taught to do good, they will learn to do evil. If they are brought up in ignorance, they are in a manner unfitted to discharge the high duties which devolve upon freemen. If the mental soil is not cultivated, weeds, and brambles, and thorns, will spring up spontaneously, to the great annoyance of the community. As every man's vote weighs alike in the political scale, it were well for all that every man had enough of good sense and independence to cast his vote honestly. And the best way to insure this, is, to lay a good foundation of usefulness in youth—to teach the hands to work, and the mind to think. "Reading," says lord Bacon, "makes a full man, and thinking a correct man." Every citizen is in a measure dependent, for the preservation of the great blessings of freedom—security for his person and property,—upon the suitable education of the rising generation.

Children in our Factories.

It has ever been urged against large manufacturing establishments, that they tend to impair the health and deprave the minds, of the numerous children who are usually employed in their manipulations. The evil became so apparent and alarming in Great Britain, a few years since, as to call for official investigation; and on inquiry it was ascertained to be worse than was apprehended. Thousands of miserable victims of oppression, were found growing up in ignorance and vice, alike disgraceful to themselves, and dangerous to the community. And from being compelled to labor twelve to sixteen hours in twenty-four, in confined apartments, and fed on coarse and scanty food, they were generally in a sickly condition, and many had died from hardship and want. Parliament applied a prompt, though in the opinion of some, not a sufficient corrective. It excluded children under a certain age from these establishments; restricted the labor to ten hours in a day of the younger class to be employed, and we believe made some provision for their being educated.

This evil has also produced a legislative investigation in Pennsylvania; and the committee appointed to examine into the matter, we are sorry to say, have reported a state of facts disreputable to our country, and have proposed suitable correctives. The report is accompanied by the testimony, on oath, of a large number of operatives and employers. It states, among other things, that no particular attention is paid to the education of the children employed in the manufacturing establishments; that of all under eighteen years of age, not more than one-third can read or write; that the long hours of labor, (generally twelve hours per day,) close confinement, and vitiated air, have proved extremely injurious to the health of the children employed, those under twelve comprising one-fifth of all the operatives in these establishments.

The report recommends, that hereafter, no child under ten years of age shall be employed in these factories; that children in factories not able to read, write and keep accounts, shall be sent to school at least three months in every year; and that children under sixteen shall not be allowed to labor more than ten hours a day. "The destitution of education," says the Commercial Herald, "and moral culture, among the factory children, is astonishing. In the majority of instances children enter and grow up in our factories, without being able to spell, read or write. With broken constitutions, from excessive labor in youth, harassed with disease, and brutalized with savage ignorance, they reach manhood fit instruments for the purposes of demagogues, and ripe for every sort of crime and violence." "Where children are thus raised in ignorance," says Mr. Heastings, one of the witnesses examined, "and so totally devoid of the necessary improvement of their mental faculties, it is not to be wondered at that mobs and murders are so common in our large towns and manufacturing districts, where the people are kept in ignorance, and regarded but a little superior to the beasts that perish."

We have referred to this subject, in the hope of turning the public attention to the matter in our own state, where, if the like evil exists, it becomes the interest and the duty of all good citizens to see it promptly corrected.

Smut.—The fact is well authenticated, that after the seed of smut has been destroyed by steeping the seed in pickle, the *virus* may be again communicated to the seed grain, so as to affect the crop. Bauer took some kernels of wheat, which had been purified with salt and lime, and inoculated them, as it may be termed, with the dust of smut brand, that is, by pressing some of this dust into the suture or crease of the grain, and the product was smutty. This dust, or seed of smut, may adhere to a bag, to a barn floor, or indeed may be left in the soil, and, as we believe was the case with Capt. Greene, noticed in our last, brought in contact with the sown seed by water in the soil.

Salt Petre.—Great efficacy has been ascribed to this salt, applied in steeps for seed corn. We cited a case in our last, from Senator Johnson, of its great efficacy in the steep for seed wheat. In our March number we stated the experiment of Hart Massy, Esq. where the nitre seemed to have added vastly to the product, and served as a complete protection against the worm. A correspondent, whose favor is now before us, says—"Seed corn soaked in a strong brine of *salt petre* was found a certain preventive against the ravages of the grain worm [wire worm, or grub, we suppose] last year. Have you tried it?" In our noviciate in farming, being desirous of making some experiments with salt petre, we desired a mercantile friend, going to New-York, to buy us a small parcel of crude, cheap salt petre. He bought us a bag of 200 lbs! We placed it in our garret, and we have used of it for fifteen years, at the rate of a pint for half a bushel of seed, in the steep of our seed corn. So far as our recollection serves us, when nitre has been used, for we think it has been partially omitted in two or three instances, we have been very little troubled with the wire or grub worm. We have ascribed great potency to tar, in protecting the seed from birds and insects; but we have now our doubts whether our exemption from their ravages should not be imputed, at least in part, to the nitre employed in the steep. We particularly refer to this subject now, in the hope of inducing satisfactory experiments in the current month. The oxygen, of which the nitre is principally composed, has a salutary and powerful influence on the germination of seeds; the impregnation of the grain with this salt may render it offensive to the worm, while it cannot fail to impart some fertility to the soil. We hope that experiments may be made in this matter, and that we may be favored with the results.

The Grain Worm.—We beg to call the attention of the reader to the communication of C. in our last number. It asserts two facts in regard to the grain-worm, at variance with received opinions. 1. That the insect is *viviparous*—not *oviparous*—that is, that it does not produce eggs, but brings forth its young in a living state; and 2, that it is not the offspring, or maggot, but the parent, or fly, which causes the mischief. From the high character of our correspondent, as an entomologist, we are disposed to pay a respectful deference to his opinion. We hope the matter will receive further elucidation the coming season.

The least of the bugs.—We would also ask the attention of the reader to another communication from "C." under the above head. It involves matters of deep interest to the farmer. The insects of which it treats are supposed to produce the ergot in rye, quack grass and spear grass (poa pratensis.) The alarming epidemic which prevailed in New-England in 1811–12, has been imputed to the deleterious effects of the ergot in rye of the preceding season. And at this time a great mortality pervades the west, among cattle, which is believed to be caused by the ergot of the grasses we have named. There is not the shadow of doubt but that ergot is poisonous to men and brutes; that it abounds upon the plants we have named, much more in some years than in others, and that without special care, it enters into the food of man and beast. Threshing and thoroughly cleaning rye, divests the grain of most of the poison; but means are seldom taken to separate it from the food of the brute. We have seen fields of spear grass, which is wont to crowd out and take the place of other grasses, as meadows and pastures increase in age, seemingly covered with ergot. The best preventive we know of in this case, is to alternate crops where it can be done, and to give such high culture as will ensure the growth of what are termed the cultivated grasses; and where this cannot be done—or where the lands are doomed to perpetual meadow and pasture, to top-dress them with dung and compost—to seed and scarify them, that the healthful grasses may be maintained and perpetuated.

Morus Multicaulis.—We would also invite the attention of silk growers to the communication of Professor Ives, in our last. His experiments go to show, that the morus multicaulis, which has made no little noise, and induced some extravagant speculations, is not a distinct species, but merely a variety of the common white mulberry. It is a peculiar trait in the American character, to believe, without examination, and upon the slightest authority, whatever promises to administer to our cupidity. We have stood alone in admonishing the public, that the multicaulis, and even the white mulberry, was too tender for our northern winters, and in advising to cultivate them in stools, so that if the tops were killed, a surer dependence might be had upon the new annual growth which might spring from the roots. And we very much fear, that unless the Brussa proves more hardy than the multicaulis, or even the alba, and we have reason to believe that it will, we must, in the north, either resort to our indigenous hardy species, the M. rubra, or come short of our expectations in being able to produce our own silk.

The Brussa Mulberry.

Six thousand plants of this species, or variety, of the mulberry, belonging to the estate of the late David Ruggles, Esq. of Newburgh, were sold at auction on the 7th April. The sale was well attended, and the plants, though many of them small, went off at an average price of about thirty cents. There were samples of cocoons and of manufactured silk, fabricated from this mulberry, both of which were highly admired. The wood of this plant, although the trees were closely planted in nursery, appeared perfectly ripened and fresh, even to the terminal points, and wholly uninjured by the cold of winter; and the impression seemed to prevail, that it is hardy enough to withstand our northern winters. Brussa, from which this mulberry derives its name, is in Asia Minor, at the foot of Mount Olympus, which mountain is capped with snow during most of the year. Brussa silks are distinguished in the bazaar of Constantinople as pre-eminent for beauty and excellence. We anticipate great national benefits from the introduction of this valuable plant.

When attending the above sale, we were presented with one hundred plants of the mulberry, by Mr. Nicholas Haight, of New-York, which were imported late in the spring of 1837, from Smyrna, as the Brussa. On comparison they seem to be identical in variety with those sold. Mr. Haight has 10,000 on hand for sale. See his communication.

Mr. Whitmarsh, of Northampton, presented us, at the same time, a bundle of plants of his Canton mulberry. They are evidently different from the Brussa, and we should think not so hardy. We have planted the two kinds presented to us, and those we purchased at the sale, along side of each other, and hope, another year, to speak more satisfactorily of their hardiness and relative properties.

Cattle Husbandry.

Although we have been in the habit of appropriating a large portion of our paper to tillage husbandry, and have particularly urged the alternation of crops, and the cultivation of roots—yet we are aware, that, in many portions of our country, and even of New-York, which has been denominated the grain-growing state, cattle and sheep husbandry must ever constitute the most important and profitable business of the farm—that meat, wool, and the products of the dairy must form the great staples of trade. The lands denominated pine lands, comprising sands and sandy loams, are particularly adapted to alternate husbandry; and even upon these, it is desirable to rear as many cattle as can be well fed, as the best means of preserving or improving their fertility. Our valleys, particularly of the larger streams, as the Hudson, Mohawk, Susquehannah, Chemung, Genesee, &c. are adapted, generally, to the culture of grain, as is also the northern section of West New-York. In these, at least, for the present, cattle seem to be but a secondary object. But the hilly district lying west of the valley of the Hudson, south of that of the Mohawk, and the basins of the small lakes, and north of the New-Jersey and Pennsylvania lines, is peculiarly adapted to cattle and sheep husbandry, as is also much of that north of the Mohawk valley, and east of the Seneca river. These districts may be made to furnish the bread-stuffs necessary for the subsistence of their population; but the great staples of trade must be farm stock and their products. Nor does this augur bad for the future prosperity of these districts. While the demands for meat, butter, cheese and wool, are likely to increase, the fertility of the soil, under judicious management, is likely to improve, and with it the condition of the population. We may confidently predict, that, at no distant day, the best portion of our population, that is, the most intelligent, the most independent, and the most republican in their principles and habits, will be found in these districts. Though there may not be so many that possess great wealth, there will be a larger portion who possess competent wealth—though not so much ostentation and extravagance, there will be less want and more substantial comfort, more equality and social enjoyment—in the cattle, than in the grain growing districts. It is worthy of remark, that in those districts where attention has been given particularly to the dairy, the condition of the husbandman has been rapidly improving. This remark applies to Orange, the northern part of Delaware, portions of Herkimer, Oneida, Otsego, &c. &c.

We gave, in our March number, some directions for renovating and improving old meadows and pastures. We now proceed to give some suggestions

ON CONVERTING ARABLE, OR PLOUGH-LAND, INTO PERMANENT MEADOW OR PASTURE.

The first obstacle to encounter, is the practice, yet too prevalent, of throwing plough-land into old field, or pasture, without stocking it with grass seeds. We lay it down as an unerring rule in good husbandry, that ploughed fields, intended to be converted in pasture or meadow, should be well stocked with grass seeds; and as next in importance, that as many species of grass seeds be sown as can be procured, or are adapted to the soil; and that, if possible, there be included the seeds of those grasses which are either indigenous to, or which are found to thrive well in, the immediate neighborhood, and in similar soils. The reasons for recommending several species are these: Each kind has its particular season of growth, and exhausts a particular food in the soil; and by multiplying the number, we are more apt to obtain a constant growth of herbage, and a far more abundant supply of feed. Thus, for instance, say a square foot of surface will support but six stocks of timothy,—this grass, growing neither very early, nor very late, the herbage would neither be abundant nor permanent. But the same square foot which would support but six plants of timothy, would support, at the same time, because every kind requires its specific food, six plants of five other species, say meadow fox-tail, red clover, white clover, orchard and tall oat grass, or species of the agrostis or fescue families. Of these six kinds, some one would be in luxuriant growth at all seasons, and the herbage would be increased from three to four fold, if the soil be good, by the admixture of the different seeds.

We cannot too often repeat, that pastures and meadows are almost as much benefitted by a rich soil, and a soil moist, not wet, as arable husbandry. The food of the grass, as well as of the grain crop, must come mainly from the soil; and if this food is scanty, the crop will, in like manner, be scanty. And again, the more nutritious grasses will not grow on soils habitually wet.

"The products of natural meadows," says Armstrong, "have been carefully and skilfully analyzed in Germany, in Italy, in England and in France, and the result shows, that wet meadows contain the smaller number of the different species of plants, but the greater number of those which are either useless or injurious; and, on the other hand, that *moist* meadows contain the greater number of the former, and the smaller number of the latter. The following simple table exhibits, at a glance, the present state of knowledge on this important part of our subject:

	No. of plants.	*Useful.*	*Useless or bad.*
In wet meadows,	30	4	26
In dry "	38	8	30
In moist "	42	17	25

"The agricultural labors suggested by these facts, are of two kinds,—the eradicating of useless, pernicious plants, and the continuance and multiplication of those which are good. The first of these objects is promoted by mowing the meadows before the seeds of noxious plants ripen, by pasturing them once in three years, by sheep, horses and cattle, in succession; by harrowing them in the spring and fall; by destroying by hand perennial weeds, and lastly, by sufficiently draining those that are wet.

"Many pernicious plants are annuals, and are killed by the first of these operations. A similar effect is produced by the second; the harrow or scarifier will destroy mosses or other weeds, whose roots are fibrous and superficial; the hand hoe will extirpate such taprooted plants as resist the harrow, and are refused by cattle, and draining will expel all worthless aquatics."*

In order to obtain seeds of indigenous kinds, which are not to be had in the shops, it is common, in Europe, to have the seeds carefully gathered by children, which being sown on a well prepared piece of ground, and taken care of, will soon yield seeds for farm culture. It is easier to accommodate the plant to the soil, than to adapt the soil to the plant.

In laying down lands to permanent meadow or pasture, it is all important to have the soil perfectly broken and pulverized; as the future value of the crop will depend upon the perfect germination of the seeds, and this cannot be expected without a thorough pulverization and preparation of the soil. It is also important to sow plenty of seed. The ground, to be sure, will sustain and nourish only a certain number of plants; yet it is better to go to an extra expense for seed, than to have a deficiency of plants. It is usual, in Britain, to sow from ten to sixteen pecks of grass seed to the acre on lands intended for permanent grass, and embracing from six to a dozen species. Another practice there, entitled to our notice, in laying down lands permanently to grass, is to sow grass seeds exclusively, that is, unaccompanied with any sort of grain. A good turf is the main object; and if grain is sown with the grass seeds, it robs the soil of much of the food which is necessary to nurture the young grass; and permanent value is thereby sacrificed to temporary and comparatively trifling profit.

The best time for sowing, for permanent grass lands, is said to be the early part of autumn, say in August or the first of September, in order that the plants may become well established before winter. Or, the more hardy kinds may be sown then, and the tenderer kinds sown upon the same field in the spring, as we sow clover upon the winter grain. As the seeds of grasses are generally small, the use of the roller, to pulverize and press the earth upon them, and to smooth the surface, is almost indispensable in good husbandry. It is considered of great advantage to give a light dressing of compost, or rotted dung, to young grass; and to avoid feeding it with heavy animals the first year, before the turf has thickened and become firm.

If the grounds laid down in grass are intended for permanent meadow, reference should be had to the grasses which are fit for the scythe at nearly the same time. For information on this point, we refer to p. 30, vol. IV, and to pages 11, 33, 47 and 63, vol. III. of Cultivator.

Should pasture and meadow be made to alternate, or should fields be kept exclusively for each? The American practice is not to alternate; and yet there seems to be substantial reasons for a contrary course. The object in both cases is to obtain the greatest quantity, and best quality of food for farm stock; and this object is promoted, in both cases, by scarifying, draining, top-dressing. Labor is as profitably laid out in improving our pasture, as our meadow grounds. But feeding and mowing have different effects upon the soil. In one case the crop is annually carried off, and in the other consumed upon the ground: Meadows, therefore, diminish in fertility; pasturing increases the fertility of the soil. Is it not proper, for this reason alone, to alternate, in order to keep up fertility? But there is another argument: Pastures soon abound with biennial and perennial plants, as thistles, mulleins, &c. which, as cattle do not consume them, mature and shed their seed, and multiply rapidly. Whereas, if occasionally converted to meadows, these plants would be cut down, before the seeds matured, and at least the biennials would be soon extirpated. These weeds are as prejudicial in pastures, in diminishing the quantity of herbage, as they are in meadows, and the same good management requires their extirpation in both.

Something depends *on the size of enclosures*. Small enclosures, say ten acres, are believed to be better than large ones. Grass grows better when there is no stock upon it, than when it is subjected to the constant tread of heavy animals; hence it is deemed economical to shift cattle occasionally from one enclosure to another. Another advantage of small enclosures is, it enables the farmer to keep different classes of stock separate, and thereby prevent injuries which often occur to weaker animals from running with stronger ones.

"Respecting the *stocking of enclosures*—(we quote from Br. Husbandry,)—it is the opinion of the most intelligent graziers, that the cattle fed upon them should be divided in the following manner. Supposing four fields, each containing a nearly equal quantity of land, one of them should be kept entirely free from stock until the grass has got up to its full growth, when the prime or fattening cattle, [or the cows, where the dairy is the prominent business] should be put into it, that they may get the best of the food; the second best should then follow; and after them, either the working or store stock, with lean sheep to eat the pastures close down: thus making the whole of the stock eat over the four enclosures in this succession:—

No. 1. Clear of stock, and reserved for the fattening beasts or cows.
No. 2. For the fatting beasts, till sent to No. 1.
No. 3. For the second best cattle, until forwarded successively to Nos. 2 and 1.
No. 4. For stores and sheep to follow other cattle, then to be shut up until the grass is again ready, as at No. 1, for the fattening beasts." p. 482.

"*Land that is constantly mown, must also be frequently manured*, or it will be thrown out of heart." There is no doubt on this point. If the crop is annually carried off, and nothing in the shape of vegetable matter returned to the soil, the land must and will deteriorate, till the crop will not pay the labor of gathering it. Those, therefore, who will have *good* permanent meadows, must, once at least in four years, give it a bountiful top-dressing of dung.

Agriculture of Massachusetts.

First Report of the Agriculture of Massachusetts, by HENRY COLMAN, *Commissioner for the Agricultural Survey of the State.*—Boston, pp. 140—8vo. 1838.

The distinguished gentlemen to whose politeness we are indebted for copies of this report, will please accept our thanks. It is the first report of a strictly agricultural survey ever made, we believe, on the new continent, and embraces barely the county of Essex. As we consider it the pioneer of many which are ere long to follow, in that and other states, of a like nature, we will endeavor in our next number to notice so many of the good practices in husbandry which it exhibits, and to point out such of the bad ones, as our restricted limits will permit, and the interests of our patrons demand.

Massachusetts Statistics.

The legislature of Massachusetts, in 1837, required the assessors of each town to make returns to the secretary of the commonwealth, before the first of October, of certain statistical facts in regard to the industrial resources of the state. These returns have been published in a pamphlet of 200 8vo. pages, accompanied by an abstract in tabular form, and a copy has been sent to us by some unknown friend. The plan of thus collecting and concentrating these data, so important to all classes, must be apparent to every one who examines the publication, and we cannot but indulge the hope, that our legislature will see the expediency of adopting the example of a sister state, as well in this, as in the liberal encouragement which she extends to her agriculture. The abstract contains the aggregates of each county. We make the following extract from the general summary, the footing of which shows, that the capital invested in the branches of industry noted, principally manufactures, amounts to $54,851,643; that the value of the annual product is $91,765,215; and that these branches of labor give employment to 117,352 of her population. We have selected but a small portion of the items.

Articles manufactured or produced.	Value.	Hands emplo'd.	Capital.
Axes, scythes, snaiths, &c.	325,956	387	196,938
Bonnets (straw) and palm leaf hats,	1,902,803		
Boots and shoes,	14,642,520	39,068	
Brushes, brooms & baskets,	289,512	350	103,095
Buttons of all kinds,	246,000	358	147,200
Cotton goods, (cloths,)	13,056,659	19,754	14,369,719
Cotton batting, thread, warp and wicking,	169,221	151	78,000
Cotton printing,	4,183,121	1,660	1,539,000
Fishery, whale, cod & mackerel,	7,592,290	20,126	12,484,078
Glass,	831,076	647	759,400
Hats,	698,086	869	
Leather, including morocco,	3,254,416	1,798	2,033,423
Nails, brads and tacks,	2,527,095	1,095	1,974,000
Oil, (refined whale & other,)	2,030,321	145	1,133,500
Paper,	1,544,230	1,173	1,167,700
Silk,	56,150	125	137,000
Stone, (granite, marble, slate and soap,)	680,782	1,177	209,950
Wool,	539,689		2,842,778
Woollen goods,	10,399,807	7,097	5,770,750

The Aim and Fruits of Philosophy,

According to the Baconian creed, should be "the multiplying of human enjoyments, and the mitigating of human sufferings;" "the relief of man's estate;" "the comfort of mankind;" "to enrich the human race with new discoveries and possessions;" "to endow mankind continually with new powers and works." Two words, says Bacon's biographer, form the key of the Baconian doctrine—utility and progress.

The odium cast upon philosophy by the events of the French revolution, excited, in the minds of many, an undue prejudice towards it, and probably deterred thousands from those studies and investigations which are most eminently promotive of human happiness. We have often heard the term *philosophy* employed, by the ignorant or prejudiced, as denoting something repulsive to our moral feelings; and yet we are indebted to it for most of the comforts and enjoyments of civilized life. It not only multiplies our enjoyments, but it teaches us how to avert the ills of life, and, when they do overtake us, how to mitigate their rigor. It calls into action those powers which distinguish man from the brute, and which are given him, with the implied promise, that the harvest shall be in the ratio of the culture which he bestows upon his mind. We make these remarks, because we have hardly yet become divested of the prejudice excited in our younger days, against whatever bore the semblance of modern philosophy; while at the same time we have sedulously studied it, under various names, and believe we have derived a profit from it, which in some measure, we hope to impart to others; and because we would excite the young reader to investigate its principles, and to profit from its precepts.

---

* Treatise on Agriculture, p. 126-7.

The writings of Sir Francis Bacon form an era in philosophy, as well as in social improvements. The following enumeration, from the Edinburgh Review, of the benefits which his philosophy has conferred on society, may tend to excite a taste, even in the farmer, for the higher and nobler studies.

"Ask a follower of Bacon," says the Review, "what the new philosophy, as it was called in the time of Charles the second, has effected for mankind, and his answer is ready—'It has lengthened life; it has mitigated pain; it has extinguished disease; it has increased the fertility of the soil; it has given new securities to the mariner; it has furnished new arms to the warrior; it has spanned great rivers and estuaries with bridges of form unknown to our fathers; it has guided the thunder-bolt innocuously from heaven to earth; it has lighted up the night with the splendor of day; it has extended the range of the human vision; it has multiplied the power of the human muscles; it has accelerated motion; it has annihilated distance; it has facilitated intercourse, correspondence, all friendly offices and dispatch of business; it has enabled man to descend to the depths of the sea, to soar into the air, to penetrate securely into the noxious recesses of the earth, to travel the land on cars which whirl along without horses, and the ocean in ships which sail against the wind.' These are but a part of its fruits. For it is a philosophy which never rests, which has never attained it, which is never perfect. Its law is progress. A point which was yesterday invisible, becomes its goal to-day, and will be its starting-post to-morrow."

$100 premium for American Silk.

An association of gentlemen have obligated themselves to pay to the treasurer of the American Institute, New-York, the sum of one hundred dollars, to be awarded in October to the person "who shall raise, and cause to be manufactured, the greatest quantity of sewing silk, on not less than one-sixteenth of an acre of land, by a succession of crops in a single season, and exhibit satisfactory evidence of the same to the committee of the said institute, on or before their next annual exhibition at New-York, together with the weight of the mulberry leaves consumed, the weight and number of cocoons produced, and the weight of waste silk and floss, and the number and quality of the trees set on the land. The amount of land, and also the weight of leaves which may from necessity be borrowed from any other source to complete the experiment, together with all the material facts, to be certified to the committee on oath or affirmation. To this statement will also to be subjoined the number and condition of the trees which are produced on the land at the end of the season." The gentlemen who sign the notice are an ample guarantee that the premium will be paid.

Operation of Marl.

Marls are held to be valuable, for spreading on land, in proportion to the quantity of calcareous matter which they contain.

Clay-marl, as it is termed, is composed of carbonate of lime, silica and alumina, with a portion of the oxide of iron or manganese. It occurs in beds, and is extensively diffused. It assumes a considerable diversity of aspect and character, as it is more or less indurated, or as the calcareous or aluminous matters prevail. When very indurated, it is frequently termed rock-marl.

The operation of marls is more slow than that of lime, and they require to be applied in comparatively larger quantity. They should be laid upon the surface, and generally well exposed to the influence of the atmosphere, before being mixed with the soil. Some marls have been found to be very deleterious, unless they have undergone this previous exposure to the air. The kinds of soils to which clay marls are most beneficially applied, are the sandy, gravelly and peaty. In this case they supply calcareous matter to the soil, and improve its texture by the addition of alumina.

The quantity of this substance applied is exceedingly various, being dependent upon the nature of the soil, and the proportion of calcareous matter in the marl. Where the purpose has been to change entirely the constitution of a defective soil, it has been applied even at the rate of from 300 to 400 cart-loads to the acre. But where the purpose is to give merely a common manuring, it is supplied in the quantity sufficient to afford an ordinary proportion of calcareous matter. It may be laid upon the surface of land when in grass, where it remains till the land is brought under tillage; and this is the best method of applying it.

Shell marl is an entirely different substance. It is chiefly a deposite of marine, and sometimes of land shells, found under a bed of peat. It may be used at the rate of twenty-five to thirty cart-loads to the acre. It can be applied to the land when in various states, as when it is in stubble, in summer fallow, or in grass. The latter is a good practice; for, as in the case of all calcareous matter, the application improves the herbage; and the mineral, sinking into the soil, prepares it well for producing crops of corn when it is broken up for tillage. Its operation is not so quick as that of calcined limestone, but its effects are more lasting. The same consequence is produced by excessive cropping after the application of this substance, as after the application of calcined limestone. The soil which has been stimulated by the action of the mineral becomes more barren than before, and it is for the most part only to be restored by rest and the action of animal and vegetable manures.—*Low.*

Experiment in Harvesting Corn.

Andrew Nicol has given in the March No. of the Farmers' Register, a statement of some experiments he made last year with his corn crop, the pith of which we abstract.

1. He took 32 loads of pine leaves on to a piece of corn, planted very close for the climate of Virginia, and spread these leaves so closely, as to give an average thickness of four inches. The corn received no after culture. The product was 75 bushels per acre, considered there a very large return. The pine leaves counteracted the effects of drought; and Mr. N. thinks, that had the covering been thicker, the product would have been greater.

2. The second experiment was made to ascertain the effect of topping, cutting up, and leaving the grain to ripen upon the standing stalk. Eighteen rows of 150 yards in length, were stripped of the fodder, that is, all the leaves, except two above the ears, were taken off on the 11th Sept.; the tops were cut from six of these rows on the 20th Sept.; six other rows of the 18 were cut by the ground the same day; and the third six rows were left to stand, together with the first six, until the corn ripened; the fourth and last six rows, from which neither fodder was pulled nor tops cut, was, on the same 20th Sept. cut off by the ground, and set up in small stooks. "The corn from each was gathered on the 2d Dec. and on the 7th Feb. shelled and accurately weighed. The following are the results, in measure and in weight:

1st 6	rows	measured	8 bu.	weight per bushel	58 lbs.
2d 6	"	"	7¾ "	"	57 "
3d 6	"	"	7⅝ "	"	56¾ "
4th 6	"	"	8½ "	"	59¾ "

These results go to show,

1. That leaves are essential, even after corn is cut off at the ground, in increasing the quantity and weight of the crop. And

2. That the mode of cutting up the whole, grain, tops and leaves, gives the *most* corn, and *heaviest* corn, and certainly improves the quality, and increases the quantity, of cattle fodder. The difference between No. 2 and No. 4, will be seen to be nearly 10 per cent in quantity, and in weight nearly as much more.

The third experiment was in succoring corn. Mr. N. considered the result decidedly in favor of the practice. Where the corn was not succored, the ears were diminutive, and the succors produced little or no sound grain. There is no doubt but succors abstract food from the plants, and if taken off (we should prefer to *cut* them off) and well cured, furnish excellent forage; yet we have hitherto doubted if the gain would repay the labor of succoring. But we do not profess to be infallible in our opinions.

A sentiment of Franklin.—"I think agriculture the most honorable of all employments, being the most independent. The farmer has no need of popular favor, nor of the favor of the great: the success of his crops depending only on the blessing of God upon his honest industry."

Knight's Mode of Grafting in July.

It is thus described in Loudon: "The head of the stock is taken off by a single stroke of the knife obliquely, so that the incision commences about a diameter below the point where the medulla (pith) appears in the section of the stock, and ends as much above it on the opposite side. The scion, which should not exceed in diameter half that of the stock, is then to be divided longitudinally, about two inches upwards from its lower end, into two unequal divisions, by passing the knife upwards just in contact with one side of the medulla. The strongest division of the scion is then to be pared thin at its lowest extremity, and introduced, as in crown grafting, between the bark and the wood of the stock, and the more slender division is fitted to the stock upon the opposite side. The scion consequently stands astride the stock, to which it attaches itself firmly on each side, and which it covers completely in a single season. Grafts of the apple and pear rarely ever fail in this method of grafting, which may be practised with equal success, with young wood in July, as soon as that has become moderately firm and mature."

The grafting clay of the French and Dutch, is unguent de St. Fiacre (St. Fiacre being the patron saint of gardening,) and is composed of half cow dung, free from litter, and half fresh loam, intimately incorporated. They prefer this to all other for excluding the external air from wounds of every description, and ridicule the idea of complex compositions. We know from experience, that cow-dung alone is an efficacious application to the fresh wounds of trees, barked or bruised accidentally, and we have saved trees by its prompt application, where the bark had been entirely removed from a foot of the stock. The common grafting wax used in this vicinity is composed of one part of tallow, two parts of bees-wax, and four of rosin, melted and well incorporated. It should be thrown into tepid or warm water, when about to be used. A larger proportion of tallow will render it softer, and more easily managed. The wax or clay checks the extravasation of sap from the wounds; prevents the too sudden drying of the wood, and excludes the rain water from the wound or cleft.

A new mode of fertilizing land,

Has been announced in France, discovered by M. Jauffet, and tested by him and others. Several French societies have endorsed the inventor's claim to merit, and a learned committee has been raised in England to test its value to agriculture. It purports to be "*a process for obtaining cheap and valuable manure, without the aid of cattle.*" The old mode of converting vegetable matters into food for farm crops, has been that of first feeding cattle with them, and of then applying the dung and offal to the soil. The inventor of this new process proposes, if we understand his project, to convert vegetable matters into food for vegetables by a summary and speedy process, without the aid of the digestive organs of farm stock. We do not see that it adds any thing to the *materials* of fertility, but merely *cooks them,* if we may use the expression, and thereby expedites their conversion into new vegetable matter. The process consists in steeping straw, or other vegetable matters, in water, in which a certain proportion of lime, cinders and soot have been mixed. Fermentation ensues, and in three weeks the manure is fit for use. The *Journal des Comices Agricoles* gives the following proportions: 700 pounds of cut straw, or other vegetable substance, five hogsheads of common water, one and one-fourth hectolitres of quick-lime, three-fourths hectolitre of cinders, and one-fourth hectolitre of soot; this mixture to be well brewed for a couple of hours: and the vegetable substances, after having thoroughly imbibed the liquid, are to be heaped together, battened down, and covered with something to compress them well together; the heap is to be watered every five or six days, or as often as the heat of the fermenting mass diminishes. The hectolitre is equivalent to about 22⅛ gallons. The straw or other vegetable matter is first cut in a machine; three men and a horse, with a machine, costing about $66, will prepare seven tons a day; and ten quintals of straw will produce 40 quintals of manure, either by the addition of the ley, or by the fermentation dilating the materials operated upon. We are afraid the discovery is not likely to prove of great benefit to this country, in many parts of which manure is not yet enough regarded to arrest the farmer's attention.

Hints in Husbandry.

[*From Loudon's Statistics of Agriculture.*]

NORFOLK.

Buildings.—Lime-wash is used as a preservative of boards. It is composed of lime, *fresh from the kiln,* and clean sharp sand, mixed with *hot* water, and *laid on hot,* stirring it up so as always to lay on sand mixed with lime. At Holkham, a brick manufactory, where bricks of all forms are made, and common bricks are cut, five parts in six, through in various directions, so as to give half and quarter bricks, angles, &c. without breaking and waste. This is one of the most complete manufactories in the kingdom. Sharp clean sand dashed on new paint is found to answer the end of imitating stone. Front edge of cattle manger rollers covered with tin, at Holkham; mangers themselves plated with iron, bottoms slate.

Improvements.—A good deal of draining done of late years; very little irrigation; among the manures are reckoned marl, lime, gypsum, oyster shells, sea ouse, sea weed, pond weeds, burnt earth, sticklebacks, oil cake, ashes, soot, malt dust, ploughing in growing buckwheat, yard dung, leaves, burning stubbles, river mud, and town manure. Marling, or claying, as it is called, [the soil being principally sandy,] has been much used for an unknown length of time, and is found of great use on the sands; laid on at all seasons, but chiefly on the clover leys in autumn, and spread to eighty loads an acre; duration twenty to fifty years. Sea ouse, a calcareous mud, forty loads per acre.

Grass.—Very little natural turf in the county, [the alternating system being generally adopted.]

BERKSHIRE.

Peat ashes, as a manure. almost peculiar to Berkshire, though they might be obtained by the same process wherever peat of the same quality abounds, as they are in Holland. An acre of peat land, at Newbery, now sells at 300 to 500*l.* though it formerly sold at 35*l.* The ashes are generally applied in March and April, from twelve to fifteen bushels the acre. The benefit two years.

Hogs.—The native breed are the best in Britain—improved by a cross on the China.

Poultry.—Near Oakingham, many are crammed for the market; they are put up in a dark place, and crammed with a paste made of barley-meal, mutton suet, and some treacle, (molasses,) or coarse sugar, and are found to be completely ripe in a fortnight. If kept longer, the fever that is induced by this continued state of repletion, renders them red and unsaleable, and frequently kills them.

YORKSHIRE.

Orchards and gardens.—A particular species of plum grows at Sherburn, and in its neighborhood, called the *Wine-sour*. It grows well in gravels and limestone, is hardy, and a good bearer. The fruit sells from 21*s.* =to $4.60 per peck, when sound and good, to 4*s.* 6*d.* when cracked and damaged. They are easily hurt by rain. [This plum is superior for preserves—may be had at the Albany Nursery.]

Live stock.—Near Leeds, where milk tastes of turnips, a tea-spoonful of dissolved nitre (salt petre) is put into eight gallons of milk, which entirely removes the flavor.

EAST LOTHIAN.

Grass.—Natural meadows or pastures are not admitted into the East Lothian system of husbandry, as they are found only where nature, or certain local circumstances render them, in some measure, unavoidable, and are never kept voluntarily, or from an idea of profit. Many farmers fallow land to lie a few years in grass, especially where it has been exhausted by long and imperfect tillage; but fields of this description are not be ranked as permanent pastures, for the object is to restore them, as soon as possible, to a state capable of bearing corn crops to advantage.

SCOTLAND.

Though Scotland was far behind England, in cultivation, till the middle of the last century, it has greatly now outstripped that country, especially in arable husbandry.

Economy of Health.

We renew our notice of this sterling work of Dr. Johnson, because it exhibits a profound knowledge of the human frame, and of the human passions and propensities, and abounds in wholesome instructions for the promotion of health and the enjoyment of rational happiness.

We have reached, in order, the fifth and sixth septenniads of life, extending from the 28th to the 42d years of man's age, which the Doctor denominates the Golden Era—the double key-stone of the arch of human life, in which our physical and mental powers are most successfully developed.

"This is the epoch," says our author, "of man's existence—provided he has not grossly violated the laws of nature and of temperance, or carried into the world with him some hereditary taint—in which all the functions of the body are so nicely balanced, that no one interferes with another. The circulation in the heart does not disturb the respiration in the lungs—digestion is performed without the slightest consciousness—sleep is a temporary death without dying—and man springs from his couch with keen appetite for food, and inextinguishable energies for mental or corporeal exertion. The organs of supply are now more than able to compensate for the waste occasioned by the ordinary wear and tear of life; because the machine has ceased to make demands for additional growth. Hence it is that we are capable, during the fifth and sixth septenniads, of undergoing fatigues of body, and excitations of mind, that would be ruinous to health either before or after these epochs of existence."

After discussing the subject of phrenology, in which the Doctor is a staunch believer, with some limitations, he proceeds as follows:

"I have hinted, a few pages back, that although the mental and corporeal *powers* attain their acme in the fifth and sixth septenniads, the intellect may yet display greater prodigies *after* the completion of that period, than it could have done *during* the golden era of moral and physical perfection. The reason of this is obvious. The mind continues to acquire knowledge long after the body has ceased to gain strength. And although certain powers of the intellect, as memory, imagination, or even perception, may be on the decline, yet the accumulated materials in the granary of the mind may, and often do, enable it to construct edifices of noble dimensions, and more durable architecture, than at earlier and more vigorous epochs of life."

This proposition is illustrated by the example of Shakspeare, Scott, Byron, Milton, Johnson, Bacon, Newton, Locke, Linnæus, &c. whose finest productions were written after they had passed the golden era, or the age of 42. These successful efforts of the mind, however, are ascribed to the "accumulated stores in the emporium of the soul, which have been laid up in earlier life." "If we hope to send forth corruscations of mind, says our author, in advanced age, we must charge the electric battery, (the minds material organ) in the prime of life. He who attempts, in the vale of years, he continues, to astonish the world with the elaboration of knowlede acquired after the completion of his sixth septenniad (42) and with energies of mind *not* exerted strenuously *before* that epoch, will find himself lamentably disappointed."

Emulation and Ambition.—"It is in the fifth septenniad that the *emulation* of youth gradually slides into the *ambition* of manhood. The change is so gradual as to be scarcely perceptible—like the mutations of figures in the magic lantern, or the transformations which fancy loves to trace in the moving panorama of clouds on a summer's eve. That which was in early life only a laudable desire to excel in literature, arts, science, or manly exercise, becomes in manhood a passion for outstripping and eclipsing our neighbors in rank, wealth, estimation, power, and all the thousand objects, paths and pursuits of AMBITION."

"What is *ostentation* in either sex, but the ambition of surpassing our neighbors, or equalling our superiors, in pomp and show? *Pride* itself is oftener nothing else than ambition, gratified and elated by the supposition, whether well or ill founded, that the individual is superior in personal importance, rank, riches, attainments, or other circumstance, to the generality of mankind."

Our author illustrates his position, that *emulation* in the school is the germ of *ambition* in manhood, by citing the cases of Napoleon and Byron among the dead, and of Peel and Brougham among the living, and continues,—

"These four illustrations might be multiplied ad infinitum, and easily made to prove several propositions, but especially the following, viz:—*First*. That the emulation of youth becomes the ambition of of age. *Secondly*. That talent is not developed at any period of life, unless it has *existed* from the beginning—in other words, that it is congenital, and not acquired; consequently that men are *not* born equal. *Thirdly*. That if any thing be entitled to the denomination of 'UNIVERSAL PASSION,' it is ambition taken in its extended sense." **

"As common economy is most advantageously practised in the season of prosperity, so the ECONOMY OF HEALTH is most beneficially cultivated when we are in the fullest enjoyment of that blessing. The stings of unmerited penury are blunted by habits of previous moderation, and so the dangers and sufferings of accidental disease are obviated or mitigated by previous attention and temperance. It is in these two meredian epochs, however, that the seeds of various diseases, sown at much earlier periods, now take an activity of growth, and bring forth their bitter fruits. But, independently of these, the germs of many new afflictions, hitherto unknown to the constitution, are firmly planted, and soon fructify with disastrous fertility. The dry-rot of the frame, CONSUMPTION, which may have lain dormant for so many years, is frequently called into action about the beginning of the fifth or sixth septenniads, by causes which had not previously operated. But the great evil—the root of innumerable evils—the proleiform malady—DYSPEPSIA—the hydra-headed monster of countless brood and Medusa mien, is the progeny of civilization—and is much more indebted for its existence and diffusion to intellectual refinement, than to bodily intemperance—in other words, its causes, multifareous as they are, may be traced far more frequently to anxieties, cares, and tribulations of mind, than to improper indulgence of the palate or senses. This *nova pestis* was unknown to, or so rare as to be underrated by, our ancestors. This assertion need not stagger us. All diseases are the creatures, or rather the creations, of circumstances. Numerous maladies of antiquity have disappeared from the tablet of nosology, and others have taken their place. It may be proper to advert to syphilis and cholera, no authentic types of which can be found among the records of Greek and Roman medicine. To come nearer home, the diseases of the heart, one of the protean forms of the malady under consideration, were so little attended to before the French revolution, as to be scarcely noticed by medical writers. The portentious scenes of that eventful period called forth such a multitude of examples of this fatal disease, that a volume was soon written on the subject by Cervisart—and the mental excitation that has ever since continued, has kept up the tendency to affections of the heart, which are now among the most prominent and dreadful of human afflictions."

* * "To prevent the corporeal malady, and to diminish, as much as possible, the mental affliction itself, the individual must tread in the steps—haud passibus æquis—of Xenophon and Byron. He must "KEEP THE BODY ACTIVE, and the STOMACH EMPTY." I can answer for the value of this precept. It prevents not the individual from throwing into the prescription as much philosophy, and even theology, as he pleases. Of the *last* ingredient it becomes not me to speak, even comparatively; but of the two other items, I can conscientiously own, that they are as 'dust in the balance,' when weighed against the Græco-Byronian receipts which I have so strongly recommended. The poor man has not far to cast about in quest of the means for putting this principle into practice. Generally speaking, he adopts it, *nolens volens;* and hence it is that the most indigent suffer less from moral ills and misfortunes, than those who are far removed from want. As a man rises in rank and riches, he becomes deprived—or rather he deprives himself—not of the means, but of the inclination, to embrace the protection which this principle holds out. Among the inferior order of society, indolence and inebriety give a fearful impetus to the shock of misfortune, and soon induce a variety of corporeal disorders, that curtail the range of life, and destroy the springs of happiness. And even in the higher quarters, where we might expect better things, the mental afflictions, or the moral adversity, appears to paralyze the energies of the soul, prostrate all firmness of resolve, and place in complete abeyance all fortitude and power of resistance against the overwhelming evil! In such condition it is no wonder that temporary solace is sought in wine and other deleterious stimulants, which only smother the flame, like coals heaped on a fire, to make the combustion more fierce and destructive afterwards. From these sources are derived many of those hypochondriacal miseries, dyspeptic torments, and even intellectual aberrations, which we every day observe.—The application of the counteracting principle in question must be left to individual ingenuity. Women have less facilities for putting in practice than men, for obvious reasons; but fortunately they bear dispensations and vicissitudes with much more fortitude than their boasted superiors—the stronger sex."

Dr. Johnson then proceeds to show, that man is punished in this world—that he has a foretaste here of his final punishment hereafter—for the wanton violations which he commits of the laws of God and man. He then proceeds:

"The same reasoning may apply to rewards as to punishments. Because virtue, and merit, and talent, are not *apparently* rewarded on this globe, it does not follow that they are not *really* so. If the wicked man carries a hell in his bosom, the virtuous may and does maintain a heaven in his breast. Of all rewards, here or hereafter, HAPPINESS must be the greatest—and we have the authority of the great Ethic Bard, as well as daily experience, that

"Virtue alone is happiness below."

Even the HOPE of REWARD in another world, based on conscientious rectitude of conduct and religious feeling, is in itself a reward beyond all estimation. It is an anchor in the storms of adversity."

Correspondence condensed.

THE GRAIN-WORM.

James Cooke, of Johnsonsburgh, N. J. professes to have adopted a successful mode of preventing the ravages of the grain-worm. The preventive consists in steeping the seed in a brine made of one pound of saltpetre, one pail of water, and two double handfulls of rye flour; and after the seed is drawn from the liquid, to put to it as much plaster as will adhere to it. It prevents injury from the worm, by causing a luxuriant growth. Mr. Cooke undoubtedly alludes to the Hessian fly, and not to what *we* call the grain-worm, as this latter has not yet reached that state. Whatever induces vigorous growth, tends to lessen the evils of the fly; but no steep, we are persuaded, will prevent the attack of the grain-worm.

QUANTITY OF GYPSUM PER ACRE.

A correspondent at Kingsville, Md. is anxious to know what would be the effect of applying a ton of plaster to the acre? And why not as beneficial in this quantity as lime or bone? Gypsum has been tried in various quantities upon land, at the rates of from one to twenty bushels per acre. In no case has any quantity above six bushels to the acre proved beneficial; and generally those who made the experiments have come to the conclusion, that no more than one to two bushels can be profitably applied to the acre. The reason why it differs from lime and bone, applied in large quantities, we apprehend to be this: It is the specific food of certain plants, not in its simple, but compound form; it combines with the other elements of these plants in a certain definite proportion; this definite proportion never exceeds say two bushels on an acre; and all that is applied beyond this is useless, otherwise than by improving the texture of a too stiff or too open a soil. Lime and bone benefit upon different principles.

CULTURE OF ONIONS.

The onion grows to full size in the northern states in *one* season; but in Pennsylvania and south, it requires *two* seasons to perfect its growth. There, the tops generally die the first season, when the bulb has attained the size of a filbert or walnut; these are planted out the second season, and come to maturity. J. H. King, of Georgetown, D. C. asks the cause of this difference, and wishes our directions for the culture of the onion.

The cause of the difference, we believe, is to be imputed wholly to climate: the warm weather of the south impairing the elaborating organs—the leaves—and consequently checking the growth, before the bulb has time to acquire the full size. We remember seeing, in the garden of Col. McAllister, near Harrisburgh, Pa. a bed of full grown onions, which the owner seemed proud in assuring us, had grown from the seed that year, and which he stated as a remarkable circumstance. We made no inquiry when they were sown, but conjecture that the seed was sown the previous autumn, a practice which, according to Loudon, is common in Portugal, and is often practised in Britain. The onion in this case attains its full size by the first of August, before the intense heats of summer. Although the onion is said to be a native of Spain, it probably is indigenous to the mountainous regions, for it seems adapted to the temperature of this latitude. It withstands our winters, especially if protected by straw or litter. The onion planted for seed is often put out in autumn, or left in the ground for a second, after the first crop of seed has been gathered; it is often sown in September, and particularly the tree or bulb bearing variety. We recommend to Mr. King to sow in autumn, say in September or October, and at mid-winter, if the state of the ground will permit.

Onions are sown in this neighborhood from the 1st to the 25th April, on rich, well prepared ground, in drills 12 inches apart, and are afterwards thinned to a proper distance. The earlier they are sown, the sooner they come to maturity; and, well managed, are a sure and profitable crop.

The tree onion is said to come from a high latitude, where the climate being too cold for them to flower and seed, the flower becomes viviparous, and bears bulbs instead of flowers.

CORN AND COB CRUSHER AND GRINDER.

M. M .McFeer, writes us from Marysville, Ten. that an excellent machine for crushing corn and cob has been invented and put in operation by Mr. William Gault, of that place. Our correspondent assures us he has seen it in operation, and that it will crush and grind from 20 to 30 bushels of corn and cob in an hour, propelled by water or horse power. Such a machine is much wanted, and will meet with a ready sale, at a fair price, in every part of the country.

MACHINE FOR SOWING LIME.

William Wells, of Plainfield, N. J. notifies us, that he has patented a machine for sowing lime, which will spread any required quantity, from two to five hundred bushels on an acre, of lime, ashes or marl. A boy large enough to shovel, will; he says, with a horse, spread 700 bushels in a day, perfectly even. The machine will hold 20 bushels for one horse, or 40 bushels for two horses.

N. B. We must inform Mr. Wells, as well as others who like him are disposed to transgress our rules, that letters for their exclusive benefit, addressed to us, will not hereafter be noticed in the Cultivator—*unless the postage is paid.*

Italian vs. *Siberian Wheat.*—We must be excused from prolonging the controversy as to the relative merits of Italian and Siberian wheat, which we apprehend would neither profit the parties, nor enlighten the public. We have given our opinion, judging from an analysis of the grain, that the two species of wheat are identically the same. When they are ascertained to be different, it will be time enough to say which is the best.

Dutton Corn.—H. H. Eastman, of Marshall, Oneida, complains, that corn which he obtained as Dutton corn, at Albany, proved an entire failure; that the stalks grew strong, and six or eight feet high; but that the corn did not ripen, while other kinds came to maturity. Mr. E. we venture to say, did not plant the Dutton corn; as this is of rather dwarfish growth, and with us has never been injured with frosts. Mr. Thorburn has informed us, that in the spring of 1837, he sold a quantity of seed corn as Dutton, which he believes was not such, as in every instance that he has heard of it has proved a large growing late corn.

Hessian Fly.—Timothy S. Olmsted, of Croton, Westchester, sends us the following directions for preventing injury by the Hessian fly. Mr. O. is informed, that this fly and the grain-worm *are not* the same.

"As soon as wheat shows two blades after sowing in the fall, sow two bushels of good wood ashes per acre. Repeat the same the first and last weeks in April, and as late in the month of May as the sower can pass over it without injury. As the first and second times are past, (that is, fall and first week in April,) I would recommend the sowing of three bushels per acre any time in April, and three in May."

An extraordinary calf has been raised by Austin Harmon, jun. of Bennington, Vt. which, on the 29th March, the day he was one your old, weighed *one thousand and three pounds!* He is of the Short Horned Durham breed. This calf, Mr. Harmon writes us, sucked the dam ten days, was then fed with new milk twenty days, and after that with skimmed milk and a little oat-meal, till he was six months old; since which he has had neither grain nor milk, but has been kept upon hay and raw potatoes.

Value of Gypsum.—Barnabas Miller, of Catharine, Chemung, has sent us the result of some experiments with plaster. A row of potatoes not plastered yielded 49½ pounds of tubers, while a row along side, which he plastered, gave 90 pounds—a difference of nearly one-half in favor of the plastered row. Mr. Miller says the difference upon his corn was nearly the same, a table-spoonful being applied to each hill, after the first hoeing. The soil a gravelly loam. Mr. M. recommends the sowing a bushel an acre on grass grounds, about the first of May, and he thinks its benefits are manifest the second season. We join Mr. M. in begging farmers who do not use plaster to *try it*—on their meadows and pastures, on their corn, potatoes, &c.

Hog manure, D. Gillet is informed, in answer to his queries, cannot be applied amiss. Hot manures, as hog and horse dung, are best applied to cold moist land, cow and fermented manures to dry or warm land. Much, however, depends upon the degree of fermentation they have undergone, and reference should be had to crops, rather than soils. If unfermented, they should be applied to an autumn-ripening crop. Mr. G. thinks the best mode of applying manures for his corn is to spread it, and then gather his land in one bout ridges. This brings the manure spread upon three furrows into the space of one furrow. There is no doubt of the superior benefit of this mode of dressing to the first crop, yet it may be doubted if it is ultimately most beneficial to the crops which follow, or to the soil.

Threshing Machines.—J. G. M. Ramsay, of Macklenburgh, Ten. asks our opinion of the relative merits of threshing machines. We have no better data to judge from, than is afforded by our columns. We repeat, the threshing machine and horse-power are distinct; and that generally more depends upon the latter, as to the points of inquiry,—if portable, cheap, simple, and requiring but one horse—than on the thresher. Most of the threshers we have seen and described, do their work thoroughly; but in relation to the horse-power, we feel wholly incompetent to decide as to the relative merits of the different ones in use.

Acknowledgments.—Among many acknowledgments that are due to correspondents, we record the receipt of twenty-four kinds of prairie flowers from Mrs. Hamilton, gathered by her on the prairies of Wisconsin, geological and agricultural reports from Gov. Everett, Rev. Mr. Coleman, Prof. Mather, Dr. Perine, and several members of congress; red blaze corn from H. Luce, &c.

CORRESPONDENCE.

Importance of the Ruta Baga Crop.

Whalen's Store, 29th March, 1838.

Dear Sir,—So much has been said and written on root culture of late, that I feel a diffidence in attempting any thing new or profitable on the subject; should you, however, find a crumb in the following worth notice, you may use it as you think proper.

I commenced raising the ruta baga five years since, and can truly say, the more I know of them, the better I like them. Last season I raised 700 bushels on ground that would measure not to exceed three-fourths of an acre, after making a deduction for fifty pine stumps on the same. I sowed the 20th June, at the rate of two pounds of seed per acre, on ground which had ruta baga the season previous, ploughed once, harrowed down, laid off into furrows two and a half feet apart, two-thirds filled with long manure; a two bout ridge thrown back on the same, and the seed sown on top; hoed twice, passing the cultivator each time, and thinned down to one foot apart in the rows. A frequent mistake is crowding the plants too much; they must have room, air and light; all they are crowded nearer than rows two and a half feet apart, and a foot in the row, will surely diminish the amount of crop.

Two pounds of seed to the acre will give generally four times the number of plants necessary; but I find the extra expense of seed and trouble in thinning out amply repaid by the saving of time in transplanting and filling up vacant places; besides the transplanted ones never do as well as those left undisturbed.

As an experiment, I commenced the 1st September last, depriving every second row of all except the crown leaves, feeding them morning and evening to my milch cows. The result was, the milk increased nearly fifty per cent; the crop, when gathered, showed no difference in the rows. I pulled, topped, bottomed and put into the cellar with ease, at the rate of 100 bushels per day to each hand. I calculate the cost in the cellar at four cent per bushel. My store pigs have been wintered on them raw, with no addition, save the wash from the house and a little buckwheat and rye bran; they look well, and when I undertook a few days since to substitute raw potatoes, they would hardly deign to touch them.

I have tried mangold wurtzel each year of ruta baga, and were I to give any instruction as to its culture, would say, like Cobbett in his Cottage Economy, "wherever you see ruta baga, read mangold wurtzel," only sow early in May, and soak your seed at least twenty-fours hours in tepid water. I consider ruta baga much the most certain crop, and the difficulty in preserving through winter much less.

My drill-barrow sows most kinds of seeds; is pretty much of my own inventing two years since; cost in making about $2.50. Can all be made by a common carpenter, except the tin barrel; sows as much and as well as those costing $10 or $12. It is a great labor saving machine, every person engaged in root culture should have one. I am sanguine in the belief that the root culture will continue to increase here in the same ratio it has done in Great Britain, and that eventually the revolution in our agriculture from that source will be equally great with theirs; and whilst we see two blades of grass growing where but one grew before, we shall soon find ten bushels of roots growing where a short time since not one was thought of.

Respectfully yours,
J. Buel, Esq. SETH WHALEN.

Improvement of Grass grounds.

Cedar Brook, Plainfield, N. J. 22d Mar. 1838.

Jesse Buel, Esq.—Dear Sir,—I am a general convert to the *new system* of husbandry, but not without some important exceptions. Nothing is more common, than while we are endeavoring to avoid one error, to run into another in a contrary direction. I remember a remark of an elderly man many years since, who observed, that he had been endeavoring for a long time to understand and follow the *true* line, but he had come to the conclusion, that he was never *on* the line, except when he was crossing it.

I believe in the propriety of a rotation of crops on a large proportion of our lands; but I am acquainted with many pieces of meadow and pasture lands in New-England, the former of which are more valuable than any lands in that part of the country, which have never been ploughed within the memory of the present generation, which, in favorable seasons, produce two good crops of hay, and yield much after feed, with only a top-dressing of manure once in two or three years; and if not fed *too close* in the fall, do not deteriorate; while the pasture lands, without top-dressing, are a perennial green. Some of these lands, within the last twenty years, have been ploughed to make them *better* by a rotation of crops. They generally produced abundantly for two or three years, and after seeding with grass, yielded heavy crops of hay for about two years, and would then, notwithstanding top-dressing, begin to run out, as it is termed in New-England, so as to make it necessary in a few years to plough again, and when ploughed again, did not produce half the amount that followed the first ploughing. I am aware that the lands might have been preserved in good heart by *expensive* manuring; still I am of an opinion, that they were *essentially injured* by destroying the native rich sward.

I had charge and was a proprietor of a large manufacturing establishment in Connecticut, erected during the late war, connected with a firm of about ninety acres. A piece of ground of about four acres, near the river, above high water, but where the bed of the stream, probably at some former period, had run, had never been ploughed to the knowledge of any of the neighbors, but had been for years pastured and mowed. Indeed, it was so full of large stones as to discourage the use of the plough, besides it was considered leachy land, that was almost useless to manure. I examined the soil, and found it from two to four feet, sand, coarse gravel, stones of all sizes, to four feet diameter, interspersed with alluvial deposite. As it was convenient to irrigate it from the pond, I determined to make an experiment upon it. The native grass was principally white clover and spear grass, but was intermingled with brakes, small bushes, vines and weeds, and did not usually yield more than half to three-quarters of a ton of second quality of hay to the acre. By blasting and digging, all the stones from the surface were removed and placed in heavy walls, the holes were filled with decayed chips and wash from the roads; the ground cleared on the surface, without breaking the old sward more than was necessary. I was then advised to plough, as the only way to subdue it and get it into good grass. I determined not to disturb any more of the native sward, though quite thin and broken. We had prepared about 200 loads of good compost, which was carted and spread upon it; then sowed white and red clover and timothy seed freely, had it raked over, and all the little stones and sticks removed. The water was turned on the next spring when needed; a very large crop of grass, intermingled with some weeds, was ready to cut by the last of June. By the 1st September a great crop of rowen was produced. The following year it produced principally spear grass, mingled with clover and timothy, of superior quality and a great burden, estimated at more than three tons per acre, and the second crop full one and a half. By the middle of October, the grass was six inches in height and very thick; no creature was allowed to graze in the field. The next season it was top-dressed with about twenty loads of compost to the acre: the crops were equal, or superior, to the previous year; the ground was covered with a firm sward, and had a rich appearance. We reclaimed about four acres more in the same manner, on a moist and richer soil, and with *equal success,* without the advantage of irrigation, part of which had been considered so worthless, that it was not fenced, but left in commons. From about eight acres we calculated annually to obtain more than thirty tons of first quality of hay at two crops, and one year the estimation was as high as thirty-four tons. These meadows did not depreciate with a top-dressing biennially, but they were never fed, as I have been long satisfied that it is difficult to have good meadow and pasture on the same land annually. From the accounts of the expenses, estimating the value of the land before it was improved, preparing the ground, including the walls, about four feet wide at the bottom, five and a half feet high, capped with flat stones thirty inches wide, value of manure, seeds, cultivation, &c. the product netted more than twelve per cent per annum on the whole investment, the hay being mostly sold to inhabitants attached to the manufactory. When we sold the premises in 1824, these meadows were considered equal, if not superior, to any in the county.

Some other experiments I made, which perhaps I may hereafter communicate, should you judge this worth a place in the Cultivator.

I was more successful in farming in Connecticut than I have been *thus far* in New-Jersey.

I am, with much esteem, yours respectfully,

D. L. DODGE.

The Importance of Manufactures to Agriculture.

There is probably no branch of science of more importance to a nation, than political economy, inasmuch as "the physical well-being of a community is an indispensable basis for every thing else. Without it all the rest is fearfully insecure." The causes affecting the welfare and prosperity of a people, are as immutable as are those controlling the planetary system. We have, it is true, the power of violating the causes which contribute to the well-being of nations, but never with impunity; for so sure as we are found transgressing them, so sure shall we be punished for our temerity.

There are three sources of wealth, agriculture, manufactures and commerce. Agriculture is the most important, as it employs a much greater amount of labor than both the others, and as it is the foundation on which the others are supported. Manufactures is the second greatest source of wealth, and commerce is the lowest on the scale; yet on commercial enterprise both the others are sustained and made profitable.

Our farmers appear to be generally uninformed as to the causes affecting their prosperity. It may appear presumptuous in an obscure individual, to pretend to superior knowledge on this subject, yet, if my positions shall carry conviction to all who will attentively consider them, I shall not have presented them in vain.

The farmer makes his returns annually, and on the prices of his products his profits must depend. He can sustain himself under moderate profits; but the prices at which he sells his products must be sufficient to sustain his family, and keep his tools and cattle in good order, or he sinks. To understand, therefore, the causes affecting the prices of agricultural products, must be to him all-important. The object of this short essay is to make this clear to the commonest understanding.

We will suppose our country to contain three millions of families; that two millions are employed in agriculture, and one million in the other two branches of industry. It is not pretended that this division is statistically correct, nor is it necessary it should be, as the reasoning from it will be found equally conclusive, whatever may be the relative proportions. We have then two millions of producers to one million of consumers. We will take it for granted also, that the two millions of producers can at all times furnish sufficient surplus products to supply all the wants of the one million of consumers; and that this relative proportion of consumers to producers, is necessary to sustain agricultural products at remunerating prices. Now, it is self-evident, that we cannot change the relative proportion of consumers and producers, without causing a change in the price of agricultural products. If the proportion of consumers be increased, the price of products will necessarily rise; on the other hand, if the proportion of producers be increased, prices must as surely be lowered.

We can now understand, why the agricultural products of this country have been gradually increasing in value for the last five or six years. Our manufactures were in so flourishing a condition, that new ones were starting up in every direction, and our commerce had increased with equal rapidity. These extensions drew off from agriculture a portion of her producers, and greatly increased the proportion of consumers. Add to this, the tens of thousands that were employed on canals, rail-roads, public buildings, &c. and it will be easily estimated, that our consumers had increased until they were almost too great for the means of supply, thereby increasing rapidly the prices of every article of agricultural consumption.

Within a year past a radical change has passed over the face of our country, and the result must necessarily so lower the value of agricultural products, as to bring ruin home to thousands of our farmers. I wish I could predict better results, but as things are now progressing, I can see no opening by which our farmers can escape from more depressing prices than they have experienced since we have been an independent people. Manufactures and commerce are so prostrated, that hundreds of thousands of workmen have been driven from those employments, and are fast settling on land as farmers, or employed as workmen in tilling the soil. The producers will so outnumber the consumers, that ruinous prices must necessarily follow.

It is not my province to show by what mismanagement this state of things has been produced. I wish merely to register the prediction, that our farmers will suffer severely in the end, and to show them, that manufactures and commerce can never be much depressed, without bringing ruin home to the agriculturist. They are usually the last to suffer from bad times, but their sufferings are generally more protracted when they come. I see no remedy for the evil, so long as the majority of our citizens can be gulled into believing, that the vital interests of our country are mere foot-balls for designing demagogues to kick about at their pleasure. Sudden changes are as deleterious to the political system as they are to the physical, and our citizens will have to learn by sore experience, for nothing short of personal suffering will open their eyes, that prating demagogues, however great their gift of gab, are totally incapable of wielding successfully the complicated affairs of a nation.

Commerce will soon revive from the fatal blow that has prostrated it, but our manufactures cannot be so easily resuscitated. The whole civilized world is interested in sustaining our commerce, and great efforts will be made by the manufacturers and capitalists of Europe to supply this, their best market, with their manufactures and raw material. If our own merchants cannot sustain themselves, foreign agents, with foreign capital, will fill our marts of commerce, and the profits our merchants have heretofore made, will go into the pockets of foreigners, to add to their already overgrown capital. The same foreign influence that will be employed to resuscitate our commerce, will be exerted to keep down our manufactures. It is the well known policy of Great Britain to prevent the manufactures of any other country from succeeding. It is her interest, and her policy and interest have never been opposed to each other. Our commercial cities are already crowded with foreign agents, and the late prostration of commerce will add greatly to their number. It is well known, that every foreign agent is openly opposed to our manufactures, and it is to be expected they will continue, as they always have done, to lend their whole force and interest to break them down. They consider that every article manufactured in America, prevents their selling just so much of English manufacture.

The interest of our agriculturists is deeply involved in the question: shall our manufactures be prostrated to please foreign agents, and for the benefit of foreign capitalists, or not? The time has arrived when this question has to be decided by the voice of our citizens. Our marts of commerce may answer in the affirmative; our cotton planters, from every appearannce, will lend their assistance to prostrate them; but what are the feelings of the farmers of the free states towards our factories!! will they support them, or will they look coolly on and permit them to be destroyed? W. P.

Beet Sugar.

In the introduction of new branches of industry, which promise to realize a large profit, we are prone to catch at every suggestion, however extravagant, which promises to administer to our cupidity; while those who are interested in deceiving us, take care to keep up the deception till their own turns have been served. These remarks have a particular reference to the silk and beet sugar business. The excitement in relation to both has been great—we think unreasonably so. The following criticism upon the letters of Mr. Glass, which are from a gentleman who spent the year 1836 in France and Germany, and who professes to be familiar with the process—the best process, of producing beet sugar, cannot but have a salutary effect in correcting any extravagant notions which the letters of Mr. Glass may have produced.

CRITICISM ON MR. GLASS'S LETTERS.

Sir,—Having paid particular attention to the manufacture of sugar from the beet in France, I think it proper to mention to the public some errors which appear in the account of cost and profit, given by Mr. J. W. Glass, of Clapton, London, in his correspondence with Mr. Dey, of New-York, and by Mr. Dey communicated to you.

The cost of manufacturing in France is stated to be *just equal* to the cost of material, or rather that proportion of expense for manufacturing is set down as a very *liberal* allowance. Now in fact, the cost of manufacturing on any French plan is *twice* as much as that of the material. Thus, adopting Mr. Glass's estimate of the value of a ton of beets, viz. 15s. ($3.33,) it will result that the expense of converting the same into sugar will be, not 30s. ($6.66,) as he states, but 45s. ($9.99.)

Again: Mr. Glass says that the molasses of the beet is worth 2d. (1 cent and 8½ mills,) per pound.

The highest market price of the beet molasses in France is about 5 mills a pound, but the more common price is only 2½ to 3 mills, or 2 to 3 cents a gallon.

I do not mean to express any opinion of the merits of the new method of extracting the saccharine from beets, which is the subject of Mr. Glass's correspondence. This would be rash in the absence of all information touching the apparatus and processes by which this is effected. I merely wish to show by the above examples of error, that the evidence which Mr. Glass gives to show the excellence and advantages of the new method, is not to be relied upon. It is one thing to make an array of figures, and it is another thing to have them based on facts, and on a diligent and faithful induction from facts. And here I may observe, that no evidence of impartial, practical and scientific men is adduced, to show that any such advantageous result as Mr. Glass speaks of. In a matter of so much importance as an improvement for which the inventor demands half a million of dollars, we naturally expect other proof than mere assertion, either of the supposed inventor, or of those who recommend his improvement, or negotiate for the sale of his patent.

A new illustration of the remarkable looseness of the information may be perceived in Mr. Glass's last letter, dated Dec. 8, 1837. He quotes the price of sugar in New-Orleans at 8½ to 9 cents. That price is in fact only 4¾ to 6 cents.

My object, sir, is not at all to prejudice the public against the alleged improvement; on the contrary, I would welcome it with pleasure. I only wish that the public may be on their guard against error or deception in this matter, because I am persuaded, that nothing will tend so much to retard the introduction of this new and interesting industry, as a hasty entertainment of unsound theories on the subject. Lately in France, a man of the name of Stolle, belonging to Strasburg, announced that he had discovered a method, by which, in eight hours, good white crystallized sugar could be obtained from the beet. The news flew with rapidity over France, Germany, Great Britain and the United States. If you look at the files of any paper for 1837, you will see the proof of what I say. But what was the amount of this affair? The pretended inventor was called upon to verify his pretensions in the presence of impartial persons. He appeared before them, and exhibited a quantity of liquor, which he called syrup of the beet root; he then retired, and when the time, which he had assigned for the operation, was expired, he reappeared with a specimen of fine sugar, which he *asserted* that he had made from the said liquor. This exploded Mr. Stolle's pretensions, and he passed away. Such may not be the fate of this English discoverer; I certainly hope that it may not, but for one I wait for proof. Yours,

VIATOR.

A Proposition, to facilitate agricultural improvement.

Lake C. H. Ia. 4th March, 1838.

J. Buel,—Dear Sir,—What can, what must, what SHALL we do, to elevate the standing of the cultivators of the soil? There is "something rotten in Denmark," that needs all the energy of all the friends of agriculture, to eradicate from the community. A false pride pervades the land, and a false estimate is placed upon the value of that class of community, who are the very creators of, not only all wealth, but are the very basis and only foundation of all real wealth. What shall we do to bring about that happy state of society, that once pervaded the Roman empire, when he who cultivated the soil took the first rank among all trades and occupations? One of the very best things that the friends of this whole country can do, is to make the science of agriculture take that rank that shall induce merchants and professional men to seek to make *their* sons farmers, instead of that worst of all manias that now pervades the farming community, and which induces the annual ruin of thousands of young men, by seeking to be what nature never intended them for.

"Willie is so weakly we must make a doctor of him." "And John has such a *faculty* for trade, that his father intends to set him up. Besides you know, since he came home from school, he can't bear to go to work on the farm; and you know it 'ant so genteel as a merchant." These expressions and sentiments must be weeded out of every farmer's family. And he who can devise how it shall be done, how to change the public sentiment, so as to make the farmer and the farmer's wife and sons and daughters proud of being such, will be more deserving of the thanks of his country, than he who discovers how to destroy the grain-worm; for of a truth, this is a worm that is eating out the very vitals of community. It is the very cause of all the importations of wheat into the United States, and which have blotted our fair name as an industrious, agricultural nation. The commercial and professional part of society is overburthened with useless drones. The agricultural community are borne down with a consciousness that they are neglected by legislatures, and despised by the butterflies who flutter over them in British broadcloth, consuming the fruits of the sweat of their brows. And the mania that induces farmers to seek to ruin their offspring by seeking to make them *genteel*, unless soon counteracted, will do more to dissolve this Union, than high tariff and abolition united. An indolent mode of life, or a false pride, that makes a man ashamed to earn his own living with his own hands, is a fountain that will spread more seeds of corruption through the body politic, than all others.

What then shall we do? For do we can—Do we must, and let you and I say, do we will. Every thing must have a beginning. Suppose then that we begin with an endeavor to form an

AMERICAN SOCIETY OF AGRICULTURE,

The leading principle of which shall be to elevate the character and standing of the cultivators of the American soil; and whose members shall be pledged to the promotion of domestic industry, and particularly the growth of American wool and silk, by wearing manufactures of such; and to the promotion of agricultural schools, and the establishment and gratuitous circulation of agricultural papers.

And now, you being agreed with me, that a great good may be accomplished by such a society, the branches of which shall extend into every county of the Union, will you take it upon yourself to effect the first organization? Will you draft a constitution and nominate some gentleman who will act as the first president? (I suggest the Hon. H. L. Ellsworth, Washington.) Make every editor of an agricultural paper, and such others as you think proper, vice-presidents. A treasurer should be appointed to receive *voluntary* contributions towards forming a fund to defray necessary expenses of printing, &c. and sending abroad agricultural publications, and printing a splendid certificate of membership, which fathers would exultingly show their children as a mark of honor. A corresponding secretary should be appointed in every county and principal town, who would be active in enlisting members, and communicating a mass of information to the principal secretary, &c. The grand object would be, to enlist such a mass of influential men in the society, that farming would become popular and fashionable, so that parents would no longer seek to get their children into a more fashionable or "more genteel employment."

A great good could also be accomplished by annual meetings of such a society. The delegates from every state, not only bringing together a vast amount of useful information, but rare and valuable seeds from every part of the Union for mutual exchange, and also curious specimens of vegetable and mineral products, which in time would form a most curious and unique cabinet of natural curiosities.

If the project is not visionary—if it can be carried into effect, do not let it rest. Your standing and influence will give a weight to the matter, that I, an individual but little known, cannot command. But my humble exertions and small means will be freely given to roll the ball ahead, when once started.

I think you can associate twenty gentlemen at least, with you in Albany, who will be willing to lend the influence of their names and form a nucleus, around which to form this great national bond of union and usefulness.

And if nothing else can be done, you can publish this communication, with an earnest request, that every patron of the Cultivator would say to himself, something can, something must, something shall be done, to raise the character and standing of the whole agricultural community, and I will begin in my own family. I will teach my children that no other occupation is so profitable, so honorable, or so "genteel," as that of a farmer.

I do not often write so lengthy, but the manner in which you have honored my several communications, has led me to hope that I may still be useful, and I humbly hope withal, interesting to some of my agricultural friends.

I remain, most respectfully, your friend,
SOLON ROBINSON.

REMARK.—Mr. Robinson's proposition meets our hearty approbation; and should it be favorably responded to by our cotemporaries who conduct agricultural journals, and whose opinions upon the subject we respectfully solicit,—we shall give it our cordial support,—and devise some means, if others do not do it, to organize an association, "TO ELEVATE THE CHARACTER AND STANDING OF THE CULTIVATORS OF THE AMERICAN SOIL."—*Cond. Cult.*

Conversion of Starch into Sugar.

Easton, Pa. March 20th, 1838.

Mr. J. BUEL,—Dear Sir,—If not too late to reply to the query made by Mr. Edwards, concerning the conversion of starch into sugar, you may publish the following answer:

Starch of wheat is converted into sugar by boiling it for several hours in a dilute solution of sulphuric acid, (oil of vitriol.) The acid should be diluted with twelve times its weight of water, and starch added in the proportion of 1-40th of the weight of the solution employed. Potato starch, concerning which the information was particularly desired, yields sugar much sooner, even in two or three hours. The proportions are 1 to 2 parts of acid, 400 water, and 100 potato starch. The part performed by the acid is not precisely understood, as it suffers no diminution, and causes no evolution of gas. The only necessary change, however, seems to be the addition of the elements of water to starch, in order to make the conversion, as will be seen by referring to the analysis of the two substances; and this is produced by the sulphuric acid in some unknown away.

Saussure stated, that more sugar was procured than the starch employed, in the proportion of 110.14 to 100, though this has since been denied.

As the acid remains in the liquid unchanged, it is removed by adding powdered chalk, the whole filtered, and the sugar then obtained by evaporation.

In both cases referred to above, the sugar obtained is crystallizable, and resembles the saccharine matter obtained from the grape.

Starch is converted into sugar spontaneously in the germination of grain in malting, and likewise by frost; hence the sweetness of a frozen potato, apple and some other substances.

Respectfully yours,
TRAILL GREEN,
Prof. of Chemistry, La Fayette College, Easton, Pa.

Isabella Grape Vines—Wine, &c.

SIR,—The cultivation of grape vines and making of wine is getting to be so well understood throughout the United States, through the medium of our excellent agricultural periodicals, that what I am about to write, is probably already known to some of your readers; yet the repetition of interesting facts is often of much benefit, and the results of experience in these matters can scarcely be too often repeated.

The very numerous attempts to raise grapes from foreign vines in the *open air*, have resulted in disappointment. The late Mr. Parmentier, of Brooklyn, Long-Island, devoted much labor and expense on foreign vines, to very little purpose. Mr. Loubat, also near Brooklyn, planted a large vineyard, and for some years flattered himself with *hopes*, which resulted in loss or disappointment. In some few instances in Brooklyn and New-York, where the vines were protected by surrounding buildings, the Chasselas and other foreign varieties yielded well, thereby only demonstrating that such fruit *can be* obtained, if cultivators will be at the trouble of erecting proper houses for the purpose.

The Isabella grape vine is supposed to be a native of North Carolina. It first obtained its well-deserved notoriety at Brooklyn, in the garden of George Gibbs, Esq. now of St. Augustine, Florida; and derived its new name from his lady, Mrs. Isabella Gibbs, who was instrumental in obtaining it from the south for her garden. The original parent of all the Isabella vines is now to be seen in the garden of Zachariah Lewis, Esq. on Brooklyn Heights. This favorite vine has spread itself throughout the northern states of the Union, in Canada, and has been imported into France, and drawn forth the favorable notice of the French cultivators. Almost every garden and door-yard in Brooklyn and New-York can boast of its prolific vine, always yielding abundance to the careful cultivator.

In the year 1827, I set out, at a small place near Brooklyn, the cuttings for about 300 Isabella vines, and 50 foreign vines from France and Germany. By reason of careless cultivation from bad tenants, they did not come into bearing until 1831, in which year I was able to exhibit five kinds of very fine grapes at the horticultural exhibition in New-York. I also sent large quantities to the market, and made about fifty gallons of wine, merely as an experiment, as I supposed myself to be the first who had attempted to make wine of this grape. This wine was of two kinds, made in October, 1831, and in the April following was put into bottles, and one bottle of each kind sent to about fifty persons in different parts, who were supposed to feel an interest in the matter. One kind was made of pure juice, to which two pounds of sugar to each gallon was added. The other kind was composed of one-third water to two-thirds juice—three pounds of sugar to each gallon—one gallon of brandy to a cask of nineteen gallons. Some of this wine attained five years, and was pronounced very excellent.

In the year 1832, my little vineyard bore very abundantly, and I made, in October of that year, eight barrels of wine. It was made in a variety of modes, to test the quality of the grape, and did not all prove good; but far the greater part was very excellent, and improved with age.

I will now proceed to describe my mode of planting and cultivating the vine, and of making wine.

The cuttings intended for propagation are of any well ripened wood of the *last year's* growth, embracing three or more joints or buds. It is preferred that it should be connected at the lower joint with some small part of the old wood of the previous year. These cuttings are taken from the parent vine at any time between the first of November and first of March, and immediately buried in the earth, or put under earth in the cellar; or sometimes the ends are put in a box or basket with earth, and set in a green-house, and water occasionally sprinkled on them. In the spring, if they are not placed in their permanent locations, they may be carefully set out in the garden, at one foot apart every way, the upper bud being just even with the surface of the earth. If the season is dry, they will require to be watered several times to insure their growth. They will grow a foot or more in length the first season. In the following spring they may be transplanted to their permanent places, around buildings, fences, trees, and arbors. I trim the new sprout down to three or four buds, intending that *two only* shall be allowed to grow, and these to be trained off from the root in different directions, according to the circumstances of your trellis, or supporter. My vineyard was planted in rows, eight feet apart, and vines eight feet in the rows; but after a few years the trellis became so burdened, that I took up and removed one-half the vines, and left them sixteen feet apart in the rows. Each vine, therefore, had sixteen feet of trellis, being eight feet on each side of the root. The two main branches were tied to the lower rail of the trellis, and the lateral branches tied to the rails above.

My trellis was composed of four lath, open at the top, as I supposed it was necessary that the sun and air should have a good circulation among the vines; but I am now convinced that a top surface, as afforded by an arbor, is necessary. The great exuberance of the vine causes the new shoots to run up into the air above the trellis, and the wind will prostrate and break them, unless they have a flat arbor to rest upon. The fruit hangs with great weight on the branches, which are often broken unless they can rest on an arbor, or are well tied to the upright supporters.

As there are *four* distinct *prunings*, or trimmings, required in properly cultivating the Isabella vine, I will now describe them; merely remarking, that although the vine will give fruit when some of these trimmings are neglected, yet no cultivator has a right to expect *good fruit* without bestowing the requisite time and attention to these prunings.

First, the winter pruning. This is best done in February or March, provided the vines are not frozen; but may be done at any time between October and April. It consists in reducing the old wood according to the extent of your trellis, and the age of the vine, and strength of the root. All unripe wood is cleared off—old wood thinned out, and ripe wood of the *last* year's growth shortened down to two or three buds, *except* such runners as shall be selected to cover the trellis. Much depends on judgment in this trimming. It is difficult to describe precise rules. Those who love the grape should *cut boldly*, and acquire knowledge by experience and close observation. Every branch should at this pruning be strongly tied to the trellis.

The *second* prunning, or budding, takes place about the 10th of May. The buds have then thrown out their branches an inch or two, and generally two or three branches at every bud, or joint. These must all be reduced to one shoot, or branch, always leaving the stoutest or best shoot. They are disengaged with a slight touch, and a short time would suffice for many vines.

The *third* pruning takes place about the middle of June, and sometimes earlier, and is best performed with a pair of shears, or scissors. At this time I cut off what are called *laterals*—a branch growing out of the green wood on the side *opposite* to the fruit. These laterals may be broken or cut off quite down to the main branch at any time during the season; but it is better to remove them early, before they have acquired size and strength at the expense of the rest of the vine.

The *fourth* and last pruning is called *stopping*, or *shortening*, and is done with a shears or a knife. It should be done about the middle of July, when the fruit has attained about half its growth. I then shorten all the branches having fruit on them, (except those retained for permanent runners,) by cutting them at two or three joints forward of the fruit. This is a heavy and essential pruning, and divests the vine of much green wood and leaves, and is considered important to the development and ripening of the fruit. I would, however, particularly caution the operator against at any time removing the *leaves* of the vine, except such as are attached to the laterals and shortenings, and come away with them. The leaves are vitally important to the ripening of the fruit, which is always the best in the deepest shade. Such fruit as by accident becomes exposed to the sun, is sure to be very inferior and sour.

About the 8th of June, while the vine is in flower, and throwing its peculiar and delicious perfume all around, its great enemy, the *rose-bug*, makes its appearance, and feeds with voracity on the sweet and delicate blossom. In a few days after their first appearance, thousands are seen, carrying destruction throughout the vineyard. The best remedy I could ever devise, is to go among the vines early in the morning, before the sun has warmed them into activity, and they are then easily made to fall into the hand or on the ground, and may be crushed and destroyed. A few mornings spent in this way will clear the vineyard, as they are a short-lived enemy.

In the latter part of July, the *blight* or *rot* takes place where the Isabella vines are cultivated in fields, but it is seldom seen among those cultivated in cities. Great quantities of fruit will become brown, and sometimes black, and fall off. It is not easy to account for this destruction, which is seen as much on the high as on the low vines, and no less on fruit exposed to the sun, than on that in the shade. As an experiment, I discharged with a syringe, lime-water, sulphur-water, and soap-suds upon them, and also sifted dry sulphur on the fruit, but without any sensible effect. I feared I should lose all my grapes, but, to my surprise, I had a great crop, notwithstanding the rot. I have since supposed it might arise from the exuberance of the vine, which, like the peach and apple tree, may perhaps thus disburden itself of a portion of its fruit; but even on this principle it is difficult to account for its non-appearance in cities, where the quantities of pure fruit are quite astonishing.

I have observed in the cities, that spiders and caterpillars are in some degree destructive to the green fruit. Spiders will get to the centre of the cluster, and cause the fruit to fall in single grapes, but the caterpillar attacks *the stem*, and the whole green cluster falls to the ground.

I have in a few instances trained the vines upon large apple trees, and the grapes were abundant among the apples; but I do not think this mode is to be recommended where other supports can be had. The fruit was inferior.

In the city of Brooklyn, and among high buildings, my vines have not failed to produce abundantly *every season*, during the last fourteen year. This is an interesting fact to all who cultivate the grape. At my vineyard in the country, they have declined very much, which I attribute to the neglect and ignorance of the tenants on the place. Even in the country they are much better around the buildings than in the open fields. There are from three to five clusters on every fruit-bearing branch. I have in a few instances seen six. The extremities of the vine generally produce the best fruit, and there is often much difference in the quality of the fruit on the same vine. They may be trained a great distance over large arbors, and on the roofs and around the upper windows of our high houses. New branches will sometimes grow from twenty to thirty feet in one season.

The vine is sometimes propagated by *layers*, which consists in bending down the branch into a channel dug in the earth, and burying it at a proper depth, in a curving line, with the end above the earth. Roots will start plentifully from the part in the earth, and when it is well rooted may be cut from the parent vine and transplanted. If proper care is taken, the cuttings as well as roots may be sent a great distance. I sent a quantity of cuttings, packed in moist sods in a box, via New-Orleans to Arkansas, and had the satisfaction to learn that they were all alive on their arrival, and had been successfully planted out.

In March, 1832, I sold ten thousand cuttings to William Underhill, of Teller's Point, near Sing-Sing, N. Y. I have never visited his vineyard, but understand he is a successful cultivator.

Nothing is lost in a vineyard, as the green trimmings in summer are good food for cattle, and winter trimmings, when not required for propagation, make good fuel.

OF WINE.

Although I was successful in making some good wine, yet a portion was spoiled, and I do not flatter myself that I know much about it. An excellent little book, published by Mr. Adlum, of Georgetown, who was a great cultivator of grapes and manufacturer of wine, was my best guide in wine-making. I would respectfully advise such as wish information on this subject, to obtain it, and follow the rules there laid down. My experience, however, may be of some service, and I cheerfully give it.

The grapes were gathered and thrown into tubs, without breaking the clusters, or separating the ripe from the unripe. They were broken by a common pounder, and merely cracking the skin is sufficient, and care should be taken that the seeds be not broken. The *murk* or *pomace* is thrown into a *vat*, which is covered with one or more blankets, to confine the heat and hasten fermentation. A portion is sometimes warmed and added to the mass, to give it a start. The pomace rises on the top, and the whole will continue to rise and ferment upwards for four or five days. When it begins to sink, the fine liquor, as clear as oil, may be drawn by a tap from near the bottom off the vat, as long as it will run clear. This makes the *best wine*. The pomace is then pressed in any convenient mode, and all the juice extracted. The liquor is then called *must*, and in this state it is when any addition may be made, such as sugar or brandy. Nothing will incorporate well unless added before fermentation. I added in different casks from one to three pounds of sugar per gallon; but I would advise the adding of three pounds per gallon in all cases, and I am not certain that a less quantity will preserve the wine from running into the acetous fermentation. If properly made the wine does not require brandy, nor any other spirit, and is much better without it.

After the sugar is added in due proportion to the must, it is put into casks in a moderately cool place, and just filled to the open bung, and allowed while fermenting to overflow. It will work briskly for a month or more, and when it sinks in the cask, must be filled up, so as to continue the overflow. It is best to *stop the fermentation* before it quite subsides, in order to preserve the fine aroma of the wine; and this is done by repeated *rackings*, or drawing off into casks previously smoked with sulphur, by burning in them rags dipped in melted brimstone. If any particular flavor is desired to be communicated *artificially*, it must be done while the must is in the early stages of fermentation. It will probably continue to ferment after this first sulphuring and racking; and it may then be fined, or clarified. Many substances may be employed in this. Whites of eggs—milk and sand—fish-glue, sometimes called isinglass, may be stirred into the wine, which may be racked off in a week or ten days afterwards. At every racking a quantity of sediment is removed from the bottoms of the casks, and these rackings and finings must be continued until the wine is perfectly pure. I commenced my wine-making in October, and considered it fit for bottling in the March following, when it was put into bottles, demijohns, and tight casks.

Even when *new*, the wine is exceedingly good and palatable, and diffuses an inward glow, grateful, cheering and healthful. The taste and aroma are different from any wine I have ever known, and I cannot compare it with any.

I ascertained that a measured bushel of grapes, as they came from the vines in clusters, weighed thirty-eight pounds. I also weighed 100 pounds of grapes and crushed them, and obtained a little more than nine gallons of juice; it thus requires eleven or twelve pounds of grapes for each gallon of wine.

The location of my vineyard being considered unhealthy, I have given it no personal attention since 1832; but many persons in and about Brooklyn have made good wine from the Isabella grape since that time; and I do not doubt that others will follow their example, until the Isabella wine shall become a favorite at the tables of our best connoisseurs.

There is much to be learned concerning the cultivation of the vine, and I look to the correspondents of your excellent agricultural journal, for information on this as well as other branches of these interesting pursuits. In this town last season the Isabella grapes did not come to perfection, and were sour and worthless; yet I had excellent grapes from the fine vineyard of my friend, Josiah Dow, Esq. of Brooklyn, which is twenty miles west of this place. I should like to know whether manuring is desirable? what kinds, and to what extent? what protection is best? and whether my mode of trimming is, or is not, well adapted to perpetuate the vine?

In conclusion, I would remark, that the Isabella grapes are *eatable*, and often in the market long before they are *ripe;* and consequently many people are ignorant of their excellence when in *perfection*. I give it the preference to any grape I have ever tasted, and the vine is the greatest bearer I have ever known.

I am, sir, very respectfully, your friend,
ALDEN SPOONER.
Hempstead, Long-Island, Feb. 15, 1838.

Sir,—Will some of your valuable correspondents please to give your readers information respecting those sprouts from the roots of fruit trees, commonly called *suckers?* Should they in all cases be removed? Are they proper for transplanting, and future grafting?

Many years ago one of my young peach trees was injured by mice at the surface of the ground, and was sawed off; but the roots sent up a very thick bushy tree, which was allowed to grow, and has always been the best tree on the place.

Will quince trees bear best as single standards, or in a bushy form? S.

Hempstead, L. I. Feb. 15, 1838.

Remarks of the Conductor.—The sprouts of fruit trees should be carefully extirpated, except one is wanted, as in the case of the peach above noted, to supply the place of a diseased or decayed parent,—or except, from necessity, they are wanted for stocks, to be worked; yet seedlings are decidedly preferable to sprouts for stocks, though the graft and bud will readily take upon the latter. We may make another exception. Choice plums, and sometimes other fruits, grow on their own stocks, i. e. have neither been budded nor grafted. We have the green and yellow gages, St. Catharines, and other plums growing in this way. The sprouts of these are worth preserving, as they produce fruit like the parent. Such trees are produced artificially by layers from worked trees, and also by grafting in the ground, and when the graft has produced its own roots, separating it, with its roots, from the old stock, and replanting it. Every succor takes from the nourishment of the parent. Heading down the peach, at two years old, is recommended as a means of ensuring long life to the tree, and of protecting it from the worm. The quince bears best as a standard.

Bees and Bee House.

Dear Sir,—If you think the following experiments, "the why and wherefore," would give any information on the management of bees, as a disinterested endeavor to benefit those who are inclined to embark in that branch of rural economy, you are at liberty to publish them.

In the spring of 1834 I had erected on a rock that lay near the surface in my garden, a brick house, six feet square on the base, and six and a half feet high, covered with a conical roof; a hollow column stands perpendicular from the chamber and roof, of a conical form, fifteen feet in length, and fourteen inches at the base, which is not only ornamental, but serves as a good ventilator for the colony; a door and entrance on the south side, eighteen by twenty-four inches, secured by a lock. After being ceiled on the sides and above with matched boards, shelves were made on three sides, and a good hive of bees set thereon. When the door was closed, their egress in and out was through a space made by the omission of seven or eight bricks, on the east and south sides. This stock had filled the hive with comb, but did not work on the outside and shelves as I expected; but in the course of the summer sent out two new swarms. As this contrivance did not correspond with their views, they soon made safe their retreat to the woods. Being a little chagrined, but not willing "to give up the ship," so long as there was a prospect of gaining any good, I placed the hive, the following spring, on the outside of the apiary; another swarm came forth in June; no time was lost in putting within the house the new swarm and bush on which they had collected. They made choice of the north-east corner; from the ceiling worked layers of comb down to the first shelves. I soon discovered that these shelves were on the same plan of the bottom board of common hives, securing the bee-moth a good retreat. I therefore had occasion to take down these shelves, and for a substitute put in cross sticks to bear up the comb, which left no chance for an attack by the moth; since then no appearances of their larvæ and web has been discovered.

In the course of the two preceding winters they have spared to me more than fifty pounds of honey in the comb, as white and delicious as any I ever saw, without apparently crossing them in the least.

The advantage gained by this mode of raising honey over the usual practice is, that a large swarm does better than a small one; they gather more honey, and eat less in the winter in proportion to their numbers. Instead of clustering on the outside of the hive in warm weather, they have plenty of room, fresh air, and a cool place to labor. No inconvenience is realized by comb melting down. They can also raise a more powerful defence against their enemies, and are not liable to winter kill, as in common hives. The perspiration of the bees, which congeals on the sides in moderate weather, with the addition of their heat, the ice will melt, and run to the bottom of the hive, and the bees thereby suffocate. Many a valuable swarm is destroyed in this manner. A hive that is exposed to snow, the door is oft times filled, which prevents the admittance of fresh air sufficient to preserve the life of the swarm.

The bee-moth does not often attack a large swarm; and if any, when disengaged from the comb, they drop to the floor and perish. Mice are secluded. Cattle cannot upset them. And finally, as they do not emigrate, no anxiety attends that disagreeable task of hiving them.

The usual practice of destroying the stock in order to obtain their goodly treasure, has been a matter of regret. No branch of rural economy excites the admiration of all classes of people, more than the industrious and instinctive habits of this instructive little insect, connected with the ingenuity it displays in the accurate construction of its domicil, adds to the proof of an *All-wise Power* in the works of animal creation.

I remain, dear sir, yours,
SOLOMON W. JEWETT.

Jesse Buel.
Weybridge, Vt. April, 1838.

Wheat on a Clover Ley—Peas.

New-Stockbridge, March 12, 1838.

Mr. Buel:—Sir,—Now, as I have leisure, I will write a few lines, which may be useful to some of your readers. The first is an experiment in ploughing in clover to prepare the ground for a wheat crop.

In 1834, I ploughed a piece of ground for wheat, which had grown corn and buckwheat the previous year. The piece contained three acres and one hundred and forty rods of ground, which was much exhausted, and covered with Canada thistles. I ploughed it three times, and then sowed the wheat, and ploughed in the seed and harrowed it down. The next spring I seeded it with clover, and sowed on plaster. The wheat was plump, and yielded sixteen bushels to the acre. The next spring I gave it another dressing of plaster; the clover grew very luxuriant; I ploughed it in just as it was beginning to blossom. I worked the ground the same as I did the naked fallow, except that I passed the roller over the last crop in the fall and again in the spring. The last crop I harvested the past season; it was very much injured by the rust. I am confident that it destroyed one-third of the crop, notwithstanding I got one hundred and fourteen bushels of wheat, which is about twenty-nine bushels to the acre, by weight. I can assign no reason for this extraordinary difference, but the plaster and clover.

Now a few words with respect to the pea crop. I am fully convinced, by close observation and experiment, that farmers generally sow them too thick.

In 1835, I sowed eight bushels of peas on four and one half acres of ground, and raised one hundred and seventy-three bushels.

In 1836, I sowed two bushels to the acre, with the exception of one half acre, which I was induced to sow at the rate of three bushels to the acre, to see if the result would confirm my previous experience. I found when I came to harvest them, that those which were sown thin were remarkably well podded and a very abundant crop, and that the half acre which was sown thick had only a few small pods on the ends of the vines, and were still in blossom. A neighbor of mine has been in the practice of sowing about four bushels to the acre, and has commonly got from ten to fourteen bushels. The last season, I persuaded him to try two bushels; he accordingly sowed four bushels on two acres, and he has told me that he raised over eighty bushels from the two acres. From these circumstances, it is obvions to me, that where the ground is in good condition and well pulverized, they should not be sown more than two bushels to the acre; and if the ground is very rich a less quantity would be preferable. When sown thick they obstruct the circulation of the air, and exclude the heat from the ground, and become rotten or mildewed at the bottom. They should be harvested while the end of the vine is green, as they are valuable for fodder. All kinds of farm stock eat them greedily; sheep and colts are particularly fond of them.

SIDNEY SPRING.

To prevent the ravages of the Cut-worm.

Dutchess county, March, 1838.

Mr. J. Buel,—Dear Sir,—Many things have been prescribed to prevent the grub or cut-worm from destroying Indian corn in its infancy; most, if not all of them, I believe to be ineffectual or inert, and some of them pernicious to the growth of corn. And as the season when the grub commits its ravages is near at hand, an effectual means to prevent its mischief I believe might be of vast importance to the agricultural part of community.

Believing myself to be in possession of a knowledge of means that will completely prevent the cut-worm from destroying young corn, I shall endeavor to communicate the same to you, and shall consider myself fully compensated, without any reward from church or state, if they shall prove serviceable to the farming interest.

The remedy consists simply in feeding the grub. Many farmers are in the habit of badly ploughing their corn ground for this purpose; for bad ploughing leaves much grass for the grub to live on. But the practice of bad ploughing vastly increases the labor, and consequently the expense of raising Indian corn. The better practice is to plough well at first, and afterwards to apply the remedy.

The grub is not a dainty feeder, and will eat almost any green herbage. The best I have found to be the following: young elder sprouts and their leaves, milk weed, clover, mullein, and almost any green vegetable that happens to be at hand. My time and mode of applying them, is to apply them two or three days before the young corn makes its appearance through the ground, in compact handfulls in every fifth row, between every fifth and sixth hill, pressing the handfulls, when dropped to the ground, with a tread of the foot. The grubs, if numerous, will soon collect under these handfulls, in dozens, scores, and hundreds, and there remain for shelter and food as long as they find good accommodations, which will last for ten days or more. In the mean time it will be an easy matter to destroy them with a sharp instrument, going from handfull to handfull, along the rows in which they are deposited. I have in this way killed more than two hundred under a handfull, and thus saved my corn. Handfulls of fresh herbage must be reapplied if necessary.

The remedy may appear to many at first notice almost as bad as the evil; but I believe that a smart man will gather and apply the remedy to more than five acres in a day, and to destroy the grubs when collected is an easy matter. At all events, I believe, after a fair trial, that the remedy is the cheapest and most effectual that can be applied; and depend upon it, the remedy is no quack prescription, for it has its foundation in the animal appetite and disposition, that animal nature can be more readily coaxed than driven.

Many farmers in this county have procured spring wheat to sow; and those that I have talked with, intend sowing it as early as possible. I tell them, as the grain-worm made its appearance in our county last season, there is good reason to believe that sowing about the 20th of May would be worthy of trial, so as to prevent the fly from depositing its eggs in the soft grain, as spring wheat, when sown about the 20th of May, does not come in head until after the disappearance of the fly.*

I bought some spring wheat of a man that procured it in Oneida county, and he told me that the fairest and best spring wheat he saw there, was sown as late as the 4th of June. Can this be? What are the advantages and disadvantages of late sowing spring wheat, and how late will it do to sow it in Dutchess county?

I tried your method of steeping seed corn in water near the boiling point; but I found that was cooking it too soon, for not more than one-fourth of it came up, and being under the necessity of replanting, I found the same kind of seed came up to a grain, when planted dry. Yours, &c.

A SUBSCRIBER.

Steaming apparatus—Apple Butter, &c.

New-Bedford, Merc. Co. Pa., March 1, 1838.

Dear Sir,—I am pleased to have it in my power to communicate to you something at the commencement of each volume of your exceedingly interesting and highly useful periodical. I consider agricultural knowledge (in connection with the sciences which develope its resources) as the basis upon which rests both individual and national prosperity. Whatever some may say in relation to agriculture, that the study of it is menial drudgery, I am bold to assert, that as a science, in all its affinities and relations, it is better calculated to expand the mind and generalize the ideas than any other science that ever engaged the attention of mankind. I might here expatiate, and attempt to show its vast importance to the human family—how from it necessarily flow all our temporal enjoyments and comforts, all our national strength, and whatever elevates the present state of society above the savage condition of mankind; but in the compass of a letter there is not room. Mankind have hitherto been asleep in relation to the immense importance of this subject—but are now, we hope, about to arouse from their torpor, and elevate their standard in agricultural pursuits.

In the September number, volume 2d, we have a cut and picture of an improved hog-pen and steaming apparatus. They are both perhaps very good—they may be excellent—but they are not adapted to the generality of your readers, on account of the expense of their erection. You apprised us of your intention of giving the above cuts and description in a previous number. At the moment of the receipt of the note I was in an advanced state in the construction of a steaming apparatus and hog-pen. I instantly postponed the completion, till I should discover what new ideas and suggestions the communication would contain, that I might avail myself of them, in order to make every thing as perfect as possible; the communication came. I perused it with great interest, and was surprised at finding a remarkable coincidence and similitude between that you describe and the plan I was pursuing. The steaming apparatus, however, cut me short, and caused me to defer the finishing of it one whole year; however well it may be adapted to men of capital, to a large proportion of your subscribers, and in some particular locations, the thing is nearly impossible. After deferring it as above stated, I recommenced work in order to finish it. On the resumption of the work, I was puzzling myself in thinking whether this plan or that would succeed best, when fortunately a number of the Cultivator arrived, containing an account of precisely such an one as I was erecting, by Mr. Loonis. Here I will mention the great advantage individuals receive from publications which have for their object the promotion of interests compatible with their own, when the mind and genius of thousands are at work for the furtherance of objects of great importance, and the result of their experience made known in these publications. Improvements must progress in their line, because they mutually stimulate and assist each other, confirm kindred associations of mind, prevent experimental blunders, and retrieve from oblivion discoveries which had all but attained their climax, and which, but for the aid of a kindred spirit arriving opportunely, had been lost forever. Well, the communication of Mr. Loomis arrived; was read with great interest, and gave me confidence. The introduction of the false bottom and the setting the box right over the kettle, were the suggestions I availed myself of, as I had turned the steam by an elbow clear of the furnace: my boiler is a twenty gallon kettle, first set according to your direction, the present position of which is the result of three several experiments, and answers very well. My kettle lid is made in the first place with inch oak, ploughed and grooved, and covered transversely with two inch plank, well nailed; the tube enters the centre of the lid, and is a little over four inches square inside, and enters the box near one side, which leaves one side of the lid uncovered by the box, for the purpose of introducing water through a large plug hole, by a funnel; one end of the box is a little elevated, making a small angle with the plane of the horizon, that the condensed steam and vapour may run out at the draw end; a close lid covers the box which, in the operation of steaming, is covered with a carpet, an essential requisite. On steaming my second box full, which was apples, I applied my hand to the end of the box, where the condensed steam ran out, in applying it to the tongue, it tasted very sweet; as the process of cooking progressed, the sacharine matter accumulated. I directly constructed a trough, placed the one end in a tub and the other under the box, and collected in the tub a very rich cider; by continuing the fire, I could discharge the whole of the saccharine matter, by leaving nothing but the core and vegetable fibre. We immediately commenced making apple butter and preserves of every kind, and have set apart a barrel for vinegar, which we believe is better than cider from the press; two or three buckets of water thrown over them in the finishing process, washes out the residue of the sugar. This process saves housewives immense trouble in boiling their sweet apples over the fire, and straining and pressing out the juice. The juice runs from the box toward the last of the process as thick as molasses. I prefer this for domestic use above all the other processes ever made.

WM. JOHNSTON.

Evergreens for Shelter and Hedges—Their price, &c.

Judge Buel,—Dear Sir,—I am desirous of hedging in with a good wide belt of evergreens, the front of one of our farms, lying on the Niagara river. The land was cleared up, previous to my purchasing it, à la Americana, which is to say, every thing living was remorselessly cut down along the whole front, thus leaving the fields completely naked and exposed. My object, therefore, in growing this belt, would be two-fold, viz. a fence *impervious* to both *man* and *beast*, and a shelter from the rude winds, that come sweeping down the river, and across from the Canada shore. The belt would require some two or three thousand trees, and I should wish it as complete a representative of the different kinds of evergreens as this latitude would produce, and as could be obtained at a moderate price, delivered on the bank of the Erie canal, six miles below Buffalo.

As to the hedge, I must confess myself in very great doubt in the selection of material. I had thought of the red cedar, but if the objections to this tree, are as likely to be as great in this latitude, as mentioned by Mr. Garnett in the March number of the Cultivator, as taking place in Maryland and Virginia, it would be totally useless to attempt it. Of this, however, in conjunction with your good self, I have great reason to doubt. Evergreens, locust, and thorns grow in this vicinity in very considerable variety, and I have as yet neither seen or heard, of any attack of worms or insects, and particularly solicit information on this point from any of your correspondents, who may lately have visited the cedar forests on the small islands of Lake Erie, or that grow near Toronto, and other parts of Upper Canada.

---

* So says Mr. J. Buel.

Mr. Garnett speaks of the Holley, as "sui-generis in regard to its exemption from disease." Does he mean the Ilex Opaca of Brown's Sylva Americana, and if so, would it flourish well here? The close branches and spinous leaves would make an admirable fence, and there is no doubt, with attention, in our fertile soil, the rapidity of its growth would be greatly accelerated, and its foliage at all seasons retain the brightest green. Yet I have thought of another tree still more beautiful: the flowering rhododendron, (Rhododron maximum,) and known at the south as dwarf Rose Bay, and at the north as dwarf Laurel. As it seeks moisture and shade, I should suppose our climate more congenial to it than any other in the United States, for the thermometer rarely sinks with us to zero, or rises above 75°; and besides, the air is more moist, though less foggy, than the same parallels on the Atlantic. I see no objection, therefore, to first placing a triple row of intermixed evergreens, hemlock, spruce, fir, cedar, &c. then a small space for the line of rhododendrons, then mixed evergreens again, till a sufficient breadth of trees for shelter were planted. Here then would be obtained the great desideratum, fence and shelter, for I know of no other evergreen that will flourish as a thicket in the shade of larger trees.

If no one has yet attempted this rhododendron, I should be pleased to, as also the holley, and as neither grow in our immediate neighborhood, supposing plants out of the question, I would like to know where I could obtain seed, with any directions for sowing and growth. I am told they flourish from the hills of Massachusetts, along the highlands of the Hudson, to the mountains of Carolina; and that autumn is the proper time for gathering.

And while upon the subject of trees, would that my voice might reach and have an influence with those clearing up new lands. No matter how exposed the situation may be to the rude blasts of winter, or the scorching rays of summer, in goes the ruthless axe on the front line, and never ceases its remorseless swing, till the whole land is denuded; not even a shrub being left to weep over the mournful fall of the majestic forest; but stumps, black, naked, and deformed, like so many Stygian ghosts, by the deep shades of Erebus, and as offensive to the eye of true taste, as to every principle of feeling, alone ruling over and marking the sad scene of desolation. Just such havoc has been committed all along the beautiful banks of the Niagara, and for one I would give a handsome sum to have back a belt of a few rods wide on our front, of the magnificent decidious and evergreen trees, that originally hung in soft and graceful foliage over the land.

It is objected, that if trees are left in clearing up, that they quickly die or blow down. So they will if *single*, but not if in *masses*. They then lend shade and shelter to each other; and if one occasionally decays or is uprooted, a sufficient number is still left to supply the place of those destroyed, and these daily become stronger, spreading in roots and branches, and in a few years are proof against wind and sun, and form a magnificent mass of forest verdure, that it is rapturous to behold, and that English gentlemen would give thousands of pounds could they but shew them on their estates. Sir Walter Scott pronounced our gigantic old forests as the *true antiquities* of the land, and added that he would preserve them with the same care and veneration that he would old feudal castles.

Very sincerely, A. B. ALLEN.
Buffalo, 19*th March*, 1838.

Remark.—We can assure Mr. Allen, that any attempt to cultivate a holley, or rhododendron, or indeed an evergreen *hedge* of any plant that we know of, by plants or seeds, upon the bleak bank of the Niagara river, will be but money and labor lost. The holley will hardly stand the latitude of 40°. and the rhododendron is too tender, difficult to transplant, and unfit for a fence if it would grow. We volunteer our advice to Mr. A. that he plant a thick belt, broader or narrower—as he pleases, of indigenous trees, embracing evergreens, on his Niagara exposure, to afford shelter to his buildings and his grounds; and that he add to this shelter a substantial turf fence, at least five feet broad at the base, and of corresponding height.—*Cond. Cult.*

A hint worthy of notice.

Schenectady, 2*d April*, 1838.

Dear Sir,—Since I wrote you, on the subject of feeding down wheat and rye in the spring till June, to keep it back from blossoming a month later than usual, till the fly of the grain-worm had spent his allotted time for depositing his eggs in the blossoms, I have conversed with a Mr. Smith, of Schuyler, nine miles below Utica, and advised him to feed his wheat for the experiment, which he promised to do. After a little reflection, he said that he had often mowed down *oats* after they had grown six or eight inches high, on stony and rich ground, which put them back, and caused the stalks to thicken and become strong, which prevented them from falling, or lodging, which they were apt to do on rich ground. I advised him to try the experiment on strips of his wheat, through his field, and after harvest, to give you the result. He promised to do so. Most respectfully,

Jesse Buel. D. TOMLINSON.

We think, with our correspondent, that both mowing and feeding, are worthy of an experiment, as a preservation from the worm. There is another consideration: Grain that ripens in cool weather, say late in August or September, will be heavier, ordinarily, than that which is hastened to maturity by hot weather.—*Cond. Cult.*

"To avoid the Bee-moth."

Let your bee-house and hives be kept well whitewashed, also the short boards on which each hive stands, particularly the underside; on each, place two or three quarts of fine earth, one part salt, mixed, for the hive to rest upon. Change once or twice during summer. I found good cause to abandon placing bees on the ground, as had been recommended twenty years ago. C. WHITNEY.

English Berkshire Pigs.

Mr. Buel,—Sir,—Circumstances have transpired, rendering it incumbent on me to *caution* the public against certain impositions practised in regard to the Berkshire pigs. Persons in this vicinity, either through ignorance, or regardless of their honor, are constantly palming off, as full bred, half and three-fourths of Berkshire, crossed with the hogs common in and about Albany.

They make good individuals, and would very much improve the common hog of the country; those approximating nearest to the *pure blood*, resembling them so much in appearance and colour, that a person, not well acquainted with the true breed, would be very easily deceived. I would not wish to be understood as derogating in the least, from the good qualities of this cross, but *I do protest* against the imposition of palming them off as the genuine Berkshire breed. Let them be sold for *grade* animals—for what they really are—half, three-fourths, &c. &c. of Berkshire, crossed with the "China," "Mocho," "Grass-breed" or common hog of the country.

About two years ago, a gentleman of an adjoining county engaged of me a pair of Berkshire pigs, and before I was enabled to supply him, he chanced, in a neighboring town, to meet with a lot of, to him, very fine looking pigs, which the owner represented as *genuine Berkshire*. The sequel was, the unsuspecting gentleman purchased a pair and took them home, and never discovered the deception until he compared them with some his neighbor procured of me. All the claim they had to Berkshire blood was, their parents were obtained in the county of *Berkshire, Massachusetts.*

I have not unfrequently been invited to look at a very fine Berkshire sow or boar, which their owner would affirm to be genuine, and on making some objections to their points, colour, &c. when the white colour predominated, I would be answered "why the mother was *entirely* white," &c. &c. Now, I have the charity to believe, that in most cases, it is more through ignorance than design.

There are persons in this vicinity who possess the *pure unadulterated English Berkshire* breed, which were either procured of Mr. Hawes, my predecessor, or from myself and others, that would spurn at the idea of selling a *mongrel* for full blood.

The three imported sows and boar I now own were selected in England, from different families of the same breed—still the resemblance is so great, and they breed so near alike, that a person would be puzzled to select a pig from a particular sow, when mixed in a pen together.

Some objections have been made to this breed in regard to size; to such I would observe, that in England they have been made to attain six, seven, and even eight hundred pounds.

The demand in this country has been so great, that very few of the full bloods have been fed. I killed a barrow in November, 1836, eighteen months old, fed for a short time in the fall, (after running in a pasture three months in the summer without any feed, except grass) on raw and boiled potatoes with a small quantity of soft corn; he was not fat, and when dressed weighed 312 lbs. Some of the same litter were fed and killed when nine months old, and weighed from 175 to 185 lbs. A three year old boar was altered in the spring and fed last fall, which I have been informed, weighed, when dressed, over 500 lbs. It is said they can be fattened at any age, and to very great weights, and at little expense, in comparison with other varieties.

A gentleman in Dutchess county put in a pen one of the Berkshire and one of the common pigs—fed them alike, and the consequence was, the Berkshire grew so *fat* and lazy, they were obliged to help him up to eat—while the other grew so *poor* that he required the same assistance at his meals. I do not assert this as a fact, but so the story goes.

Another gentleman, from one of our western counties, after examining my Berkshires, said to me, "I have just as good pigs at home, as these, with one exception—and that is, they have no *kink* in their tails." I need only say, that this gentleman owns a flouring mill, and "millers never have poor hogs."

Now, I do not say or pretend, that the Berkshire hogs will live on *air*—but I do say, they will grow larger and take on fat faster, with the same quantity of food, than any other breed I am acquainted with.

The demand for this breed, last year, was so great, that Mr. Lossing, of Albany, sold a pig (which he obtained of me) when thirteen months old, for $80. Others from six to ten months, were sold at from $25 to $50. Sucking pigs, only five weeks old, brought from $15 to $25 each.

My price for pigs, from six to eight weeks old, is invariably $10 each, or $20 per pair—cage to send them in, from $1 to $1.50, according to size, delivered in Albany.

Those gentlemen who ordered pigs in 1836–7 will please signify by what conveyance and to whose care they are to be sent. Some will be ready for sending off in all this month. Letters, *post paid*, will receive due attention.

C. N. BEMENT.
Three Hills Farm, Albany, May 1, 1838.

Agriculture—Its Usefulness.

Agriculture is a branch of business of the highest importance to mankind. By far the greater part of the human race are either directly or indirectly dependent on it for subsistence. In this region of country but very little is obtained for the support of man, but what may either be justly denominated agricultural produce, or is in some way or other derived from it, as for instance, the most of our animal food.—From these considerations arises the importance of the subject, and consequently its dignity; and hence the laudable pursuit of agricultural employment. The maximum of praise, however, is not due to him who labors with the greatest assiduity or energy, nor even to him who uses his tools with the greatest dexterity or skill. For, as according to the old maxim "a spur in the head is worth two in the heel," he may be most beneficial, to the community at large, who officiates in some department of the business which requires principally the exercise of the mental faculties. And, so every one in the subordinate sense in which his labors are beneficial to mankind, has a claim on his fellow men for their respect. Y.

Experiments in producing improved varieties of Indian Corn.

Baltimore, April 6, 1838.

Judge Buel,—In the last number of the Cultivator (page 51) I observe the following remark by the conductor:—"The idea of improving our corn by artificial crossing, is novel, yet perfectly philosophical."

Some ten of twelve years since, I instituted a series of experiments in crossing different varieties of corn, and was perfectly successful. The variety of corn named in Dr. Brown's list (page 43 of the same number) "No. 16, Pennsylvania 8 rows, called Smith's early white,"was the result of one of the experiments. It was produced by what we call the *Tuscarora*, or "New-York cheat," with the *Sioux* (No. 9 of Dr. Brown's list.) From the parentage of this new variety, you would naturally expect a mulatto color; but I will explain why it is *pure white*, as I go along. I had two objects in view, the one to get the large white grains of the Tuscarora on the small cob of the Sioux; and the other to produce a variety earlier than either, if possible. To accomplish my object, I planted a piece of ground, say the eighth of an acre, with both varieties, one in each alternate hill; but as the Tuscarora was known to me to be from 15 to 20 days later than the Sioux, I planted the latter 15 days after the former was planted. Now the process of crossing is performed in the following manner. The variety that has the cob that I wish to retain, is used as the female, and as the tassels (male flowers) appear, they are carefully cut off and suppressed; the variety whose grain I wish to get, is used as the male, and its tassels are allowed to grow. It is unnecessary to interfere with the female flowers (the silk.) The ears of corn produced by the Sioux hills had the form and size of cob of the Sioux, but the grain was a beautiful sulphur color, and of the form of the Tuscarora, though smaller. This corn I planted the next year, and the result was, a beautiful variegation of the grains, of pure yellow and pure white, though all the grains were alike as to size and shape. The cream color had evidently returned to its original elements. I then carefully selected the white grains, and planted them the third year, and the result was the establishment of the variety called "Smith's early white."—(I do not understand how or whence Dr. Brown obtained the name of *Pennsylvania* 8 rows.)

My experiments established the fact, satisfactorily to my mind, that you can place the grains of any variety of corn upon the cob of any other variety, by the process detailed above; and that there is no object more worthy the attention of farmers than improvements of this kind. You have only to regulate the time of planting each variety, to correspond with the time of flowering. I ought to observe, that if you do not destroy the tassels of the variety that has the objectionable *grain*, the crossing will not be so perfect, because the *impregnation* will be from two males instead of one, and consequently the grains produced will be various. The crossing is equally important in producing the large late kinds small and early. You can get the tall Virginia corn (that is the grain of it) upon the early dwarf stalks. Indeed, you may vary it almost at pleasure. As you will perceive above, it requires three years to accomplish the object perfectly. The first year effects the crossing; the second year, certain characteristics return to their original elements, such as the color, and somewhat of the flinty quality; the third year the new variety is produced perfect—and will remain so, so long as it shall be kept distinct from other varieties.

Another experiment was combined by me with the above, viz.—the first matured ears of good form and size were always selected for seed. By this process I was able in five years to make my new variety from 15 to 20 days earlier than the Sioux, or any other variety. I had green corn on my table for some years, two weeks earlier than the hotels who obtained early corn from Norfolk. I beg to observe, that the Smith's early white has but eight rows, and the Sioux (the female parent) twelve; now to account for this. After I had produced the variety, I was still desirous of putting it upon a smaller cob; hence I planted it with the sugar corn, using the latter as the female.—The result was the eight rows. I also once took a notion to give it a red cob, and had no difficulty in doing so, by using the red cob sugar corn as the female; but I recrossed and got rid of the red cob again, because it stained the lips and fingers while eating it.

Excuse this, from an old admirer,

GIDEON B. SMITH.

Judge Buel,—Sir,—I commenced raising ruta baga turnips last season, and am much pleased with the result. In order to ascertain when was the best time to sow them, I sowed some the first day of June, some the 13th and some the 24th day of June, and found that those sowed first were much the best. I would recommend to sow as soon as the 25th of May in this latitude, 43° 30′ north. I prepare my ground by ploughing in long manure, and spread fine manure on the furrows, and only harrow it in after the ground is well harrowed. I drag it with a bush, which completely pulverizes and mixes two or three inches of the surface of the ground.

I make my bush by boring holes in a stick six inches in diameter, six feet long, with a large auger, and fasten in bushes eight feet long, and then lash on another stick of sufficient heft across the middle, to keep them in place. I would recommend to bush all land that is stocked with grass seed for mowing. Those that cannot obtain a drill-barrow, may make a thing like a rake, with a tooth in each end of the head, one inch thick, sharp at the point, and mark the ground, and sow turnip seed by hand, or any other seeds they wish to sow in rows.

My method of harvesting turnips, is to take a sharp hoe and chop off the tops first and gather them into heaps, and then dig them with hoes,[*] which is a more expeditious way than to pull them by hand, and then cut the tops with a knife.

My land is a light sandy loam, not naturally good wheat land. Last spring I commenced liming my wheat ground; I put six bushels of unslaked lime on half an acre after the land was ploughed. I put a peck in a place, and covered it with earth, and let it remain three days, when it was completely slaked, and then spread it evenly over the ground, and then sowed my wheat and obtained a good crop, and no smut. My wheat was sown the 27th day of May; on the same day one of my neighbors sowed one acre and a half with the red chaff beardless wheat, and obtained sixty-one bushels from it.

A. C. HOWARD.

Thetford Post Mills, March 27th, 1838.

Brussa Mulberry.

New-York, April 7th, 1838.

J. Buel, Esq.—Dear Sir,—You will herewith receive one hundred Brussa mulberry trees, which please accept for inspection and for your own appropriation. This is an original tree, imported in the month of June, 1837, from Smyrna, and were so long detained in their passage, as to make their growth doubtful—but from a quantity, a portion vegetated and grew from the root and slip, as you have herewith. They are, undoubtedly, the real Brussa tree. As the consigners had no knowledge whether or not it would be a favorite tree with us, for this cause the best, that even at the time they arrived here, no information was communicated to the public that the Brussa tree was of a superior kind, nor not, indeed, until you brought it forward through the valuable columns of your paper. It is no doubt one of the most valuable that has ever been introduced; and to satisfy the minds of the wavering, your opinion would, if communicated through your next journal, decide the matter, and silence the doubts and impressions that are exerted to be made on those who are desirous of purchasing, by the gentlemen of Flushing, who have not the tree. I have this invoice of trees to sell, and have about ten thousand or more; and although I intend to go on propagating, still I must close the whole invoice, they belonging to the owners residing in Smyrna. Yours,

NICHOLAS HAIGHT.

EXTRACTS.

Science of Gardening.

The extracts which we shall give under this head, are from the "*Alphabet of Scientific Gardening*, by Prof. Rennie, of King's College." They are as applicable to farming as to gardening. They elucidate the great principles which govern in vegetable economy; and although they may seem abstruse to some, they nevertheless furnish valuable data, which all may profitably recur to; and we commend them particularly to the notice of the young, who aspire to usefulness, or eminence in the arts of rural labor.—*Cond. Cult.*

ARTS AND SCIENCE.

"The arts," says Sir John Herschel, "cannot be perfected till their whole processes are laid open, and their language simplified and rendered universally intelligible. Art is the application of knowledge to a practical end. If the knowledge be merely accumulated experience, the art is *empirical;* but if it be experience reasoned upon and brought under general principles, it assumes a higher character, and becomes a *scientific art.* In the progress of mankind from barbarism to civilized life, the arts necessarily precede science. Applications come later: the arts continue slowly progressive, but their realm remains separated from that of science by a wide gulf, which can only be passed by a powerful spring. They form their own language, and their own conventions, which none but artists can understand.—The whole tendency of empirical art is to bury itself in technicalities, and to place its pride in particular short cuts and mysteries, known only to adepts; to surprise and astonish by results, but conceal processes. The character of science is the direct contrary. It delights to lay itself open to inquiry; and is not satisfied with its conclusions, till it can make the road to them broad and beaten: and in its application it preserves the same character; its whole aim being to strip away all technical mystery, to illuminate every dark recess, and to gain free access to all processes, with a view to improve them on rational principles. It would seem that a union of two qualities almost opposite to each other—a going forth of the thoughts in two directions, and a sudden transfer of ideas from a remote station in one, to an equally distant one in the other—are required to state the first idea of *applying science.*"

THE WORD GARDENING.

The chief difference between "Gardening"[*] and Farming appears to exist in extent. The surface tilled being more extended, and the crops produced being often more coarse and hardy in farming, the operations require less minuteness and refinement, which, indeed, would seldom yield the farmer an adequate return for the money laid out. Whereas in gardening, the most refined and minute processes are frequently indispensable, in proportion to the delicacy of the plants which are reared, more particularly with respect to artificial shelter and artificial climate. Gardening, then, is a sort of refined farming upon a limited scale.

By "Scientific" Gardening, I mean the rearing of garden plants of every kind, useful and ornamental—kitchen vegetables, roots, fruits, and flowers, according to principles capable of being demonstrated by experiment or inference. What may, on the other hand, be called *routine* gardening, is founded not upon such principles, but upon vague and uncertain experience.

Nobody, I think would be so fool-hardy as to question the high value of experience; but mere experience, without the aid of science—I mean experience without accurate investigation of causes and effects, and without sound reasoning from observed facts—is just as apt to mislead as it is to direct aright, and often, I believe, much more so. Science again without experience will equally mislead.

The value of scientific knowledge in gardening being thus indisputable, it will be important to render it easily attainable, by putting the facts upon which it rests in as plain a manner and in as short a space as I can. For this purpose, it will be most advantageous to consider, first, what it is that nourishes garden crops, that is, the food which garden plants require; and then, upon what scientific principles this food can be best supplied by the gardener in his daily operations. He might, indeed, as well think of rearing rabbits or canary birds as of raising garden crops without food. My subject accordingly has two grand divisions—the Food of Plants, and the Philosophical Principles of Garden Operations for the management of this food.

FOOD OF GARDEN PLANTS.

It is obvious that a cabbage, a pine apple, or a primrose, can no more live without a due supply of food, than a rabbit or a canary bird; but animals must moreover have a peculiar kind of food; the rabbit, greens and oats; and the canary, rape, millet, or other small seeds; while in the case of plants, which are fixed to a spot, and cannot travel about to select their food, such differences, when they do exist, are not often of practical importance, the food of all plants being nearly, so far as it is known, very similar in kind.

The principal difference in most garden plants compared with others, is their greater delicacy; and hence so far as practice is concerned, their food must require, if I may use the term, more delicate and refined *cooking* and management. This will appear as we proceed, in the several branches into which it will be advantageous to divide our subject, beginning with what may be termed Garden Chemistry, meaning thereby a detail of the chemical elements which enter into the food of garden plants.

GARDEN CHEMISTRY.

Passing over, for the present, the food on which young plants are nourished at their first germinating from seed, which is as different, as we shall afterwards see, as the milk diet of our own infancy is from beef and bread, let us consider the food requisite for plants after they have exhausted the milky pulp contained in the seed lobes and seed leaves.

After young animals are weaned, they are nourished upon either vegetable or animal substances, or a mixture of both, together with water for drink, that is, a solvent to dissolve the more solid matters. These have to undergo the process of digestion in the stomach, where the heat is uniformly ninety-eight degrees, and the mixture of the various substances effected by the motion of the stomach, which is similar to that of an earth-worm.[*] On the pulpy mass[†] thus produced in the stomach passing onwards towards the chyle-gut,[‡] it is mixed with a portion of bile which separates it into two portions, one useless,[§] that passes off through the bowels, and another useful,[‖] which is taken up by the mouths of innumerable small tubes[¶] that open on the inner surface of the intestines, and after all these small tubes unite into a single large one,[**] they discharge this useful portion into the blood. Such, in brief, are the first processes by which animals are nourished with food.

Plants, on the other hand, having no stomach, like animals, for the digestion of food, and not being capable of travelling from the spot where they are planted, (except very partially by extending their roots) must depend altogether on what they can meet with there.

We find, accordingly, in the surface earth, or soil where the roots of plants are, that processes are always going on very similar to digestion in the animal stomach; I mean that portions of animal and vegetable substances in the soil are dissolved (I might in one sense say digested) and mixed with the water and air diffused through the soil.

In this point of view, the whole of the soil where a plant is rooted, may be considered as similar to the mass produced in the animal stomach by the first process of digestion, and consisting of two portions, one useful and the other useless. The soil would thence appear to perform an office similar to that of the animal stomach, in preparing the food of plants—the process, independent of other circumstances, going on more slowly from deficiency of heat in the soil, which, in this climate at least, is, on an average, far below ninety-eight degrees, which is the heat of the animal stomach.

The only thing in the soil that appears similar to the motions of the bowels of animals, by which the digested food is brought to the mouths of the little tubes, to be forwarded to the blood, is the motion[††] of the water, or moisture in which the useful portion of the vegetable and animal substances are dissolved, a motion quite indispensable, as we shall afterwards see. The water being then diffused through the soil, a portion of it must offer itself to the tips of the root fibres, or rootlets, where are suckers[‡‡] somewhat similar to those on the inner surface of the animal intestines.

It being of the first importance to ascertain of what materials the useful portion of the substances thus dissolved in water consist, many experiments have been made for that purpose; but the great difficulty of the subject has caused much diversity of opinion among those who have engaged in the inquiry. As it would, I think, be unprofitable, if not injurions, to distract the beginner with conflicting views here, which he can examine at leisure in larger works, I shall confine myself to what is least disputed and most generally adopted.

---

[*] The hoe often cuts and bruises the roots. They should be pulled with the hand, and laid in rows; they may then be expeditiously topped with a large knife or spade.—*C. Cult.*

[*] Technically, *Horticulture*, from the Latin *Hortus*, a garden, and *Cultura*, tillage; a pedantic term, of no use whatever in the English language.

[*] Technically, *Peristaltic*, or *Vermicular* motion.
[†] Technically, *Chyme.*
[‡] In Latin, *Duodenum.*
[§] In Latin, *Fœces*, or *Excrementa.*
[‖] Technically, *Chyle.*
[¶] Technically, *Lacteals.*
[**] Technically, the *Thoracic Duct.*
[††] Technically, *Percolation.*
[‡‡] Technically, *Spongelets;* in Latin, *Spongiola.*

Upon trying, by means of chemical tests, the materials taken up by plants from the soil, they are found to consist of water, with which are mixed carbonic acid gas, and nitrogen or azote, along with a few other principles, usually in small proportions, which it may be well to examine separately.

WATER.

From experiments made by Van Helmont and Boyle, who reared plants in earth previously dried in an oven, and by Du Hamel and Bonnet, who reared others upon sponges and moss supplied only with water, it was concluded that water alone is the food of plants; though the inference is faulty, in consequence of overlooking what might be contained in the water before it was used, and also what it might afterwards derive from the atmosphere, as well as from the earth or the sponge. That water, indeed, was not all the food necessary, was proved by the plants so treated not remaining healthy; and it is well known, that though hyacinths and other bulbs will flower in glasses containing nothing but water, yet they never in such cases form seed; and if thus kept for a few months, they will infallibly die, as other plants do when placed in calcined or roasted sand, and watered with distilled water. The hyacinths in glasses, moreover, are not found to thrive unless the water is frequently changed, indicating that it is not the water alone, but something in the water which has become exhausted, or at least deteriorated, by the slimy matter thrown out by the roots.

The materials, which water holds or may hold dissolved, are therefore important to be ascertained, and this may be partially known by color, taste or smell, but more correctly by chemical tests. It is only, however, requisite for gardening purposes, to discover the materials which may prove useful or hurtful, and these, for the most part, are but few in number.

Among the substances useful to vegetation, dissolved in the water of soils, may be reckoned atmospheric air, carbonic acid gas, hydrogen gas, humic acid, and a small portion of the salts of lime and potass.

Among the things hurtful, are most of the acids, the salts of magnesia, and iron, metallic substances in general, and stagnant water.

It is also important to bear in mind, that the purest water is not a simple substance, but composed, as discovered by Cavendish, of eight parts oxygen gas, and one part hydrogen gas, or two volumes of hydrogen and one of oxygen, the correctness of which composition is proved by exploding, or burning these proportions of the two gases together, when the result is pure water. Plants seem to have the power of decomposing the water which enters into their system from the earth or the air; that is, of separating it into its component parts, oxygen and hydrogen.

Socrates in Praise of Husbandry.

It was the noble aim of Socrates, the Grecian sage, according to Cicero, to bring down philosophy to the level of common capacities, to render it more useful in common life, and to apply it solely to what might make men more rational, just and virtuous. In the extracts from Socrates, below, which have been handed down by Xenophon, we find Cicero's words verified: philosophy is happily applied to agriculture, and to the common business of life.—*Cond. Cult.*

"There is no condition of life," says Socrates, "however exalted, that should exempt a man from the practice of agriculture. By exciting in the soul an arduous activity for labor, it diffuses the most pure and delightful satisfaction. In augmenting our riches, it exercises the body, and gratifies every rational wish of a free agent. The earth not only rewards the toil of cultivation with those blessings essential to the support of life, but also indulges us with whatever can contribute to the embellishment of our persons, our houses, our temples! Our senses are regaled with the most agreeable and exquisite perfumes, and enraptured with varied prospects of hanging woods and enamelled meads.—The increase of flocks and herds, necessarily arising from agriculture, is productive of a variety of aliments for the sustenance of man. But in this liberal dispensation of her choicest gifts, the earth denies their enjoyment to sloth and inactivity; requiring rather that the body, habituated to the inclemency of winter, and the fervid heat of summer, should become almost invulnerable, and capable of enduring every kind of fatigue. The task of manual labor, in obliging us to be thinly clad, considerably augments the strength and vigor of the constitution; and the necessity of rising early, incumbent on all good husbandmen, by a uniform course of exercise, renders them robust, diligent and courageous." * * "What other art so bountifully distributes to its votaries the necessary wants of existence? Or what other art so amply recompenses their care and assiduity? A cheerful fire-side in the country, and a warm bath, resists the roughest blasts of winter; and a free circulation of air, the coolness of winding rivulets, and lofty groves, abate the intolerable ardor of summer. A man of independent fortune will find agriculture the most agreeable and satisfactory of all employments, and what will find him with maxims for the strictest propriety of conduct in any station of life. In the cottage, justice is never perverted, since the best laborer is always the best paid. Humanity, and reciprocal assistance to the wants of their fellow creatures, are daily practised by those employed in cultivating the same field with the sweat of their brow. Here the general may learn to instil obedience into his troops, by following the example of the farmer, who invites his laborers cheerfully to fulfil the task assigned them; rewarding the diligent and punishing the idle. A good farmer sees the indispensable necessity of animating his laborers, in the same degree a general does his soldiers; and the hired peasant, who works for bread, has even more occasion for encouragement to perform his task with alacrity, than the voluntary companion of honor. Reverence to the Superior Being is always inculcated in the most forcible manner, from a constant series of observations, that all things are dependent on the will of Providence; that snow and hail, frost, drought and storms, blights, and a thousand epidemical maladies, destroy the fruits of the earth, and defeat the best efforts of assiduous industry, directed by consummate prudence.

"Agriculture seems to possess an incontestible right to the title of parent and nurse of all other professions. Observe a country where agriculture flourishes, and you will behold arts and sciences flourish in equal perfection. But where devastation lays waste the soil, or slothful neglect induces men to leave the earth uncultivated, a general stagnation in maritime, as well as in commercial affairs, immediately succeeds.

"I have studied, with uncommon assiduity, the characters of men of every profession, who have been distinguished for prudence and understanding. I observed with astonishment, that among those engaged in the same occupations, some were rivited in penury and want, whilst others enjoyed affluence and ease. The cause of this inequality seemed worthy of the exactest and most accurate examination; and the pains I took to investigate it at length succeeded; I perceived that those persons who formed no regular plan of life, strangers to reflection and foresight, thoughtless of to-morrow, were, by the negligence of their conduct, the sole authors of their own distresses and disappointments. Those, on the contrary, whose steady and enlarged principles govern and guide their sagacious and determined views; who unite, in their several professions, diligence and attention, order and punctuality, qualities which smooth the rugged paths of life, will find the journey more easy, more speedy, and infinitely more lucrative.—These are maxims which, whoever attends to, must gain his point, in defiance of opposition, and amass wealth, should the malignity of men, or demons, endeavor to wrest it from him.

Capital.

[*From the New-England Farmer.*]

Ah! but he has no capital to begin with! Very often, very often we hear this said; and uttered in such piteous tones, that we are in such cases almost tempted to ask, what extraordinary and melancholy destitution does this young man, who is thus compassionated, labor under; or what singular calamity has befallen him, that he is thus held up as the victim of misfortune?

He has ordinary talents and capacity for labor; he has health and strength; he has enjoyed and improved the advantages of a useful education; he has acquired, or is in the way of acquiring, a respectable and good trade; he is not the slave of any bad habits; and above all things his character is good, and he has lived without reproach. Because he has no *moneyed* capital, you choose to pity him: now I entreat you, reserve your compassion for some more worthy object. He does not demand your pity half so much as your congratulation. He is much more an object of envy than of pity. "But he has no capital." Now what is capital? In respect to trade, or the business of acquiring wealth, capital is the means or instrument of acquisition and accumulation, and is generally applied to the money or property on hand not required to be consumed for immediate subsistence, but which we can use or apply for the purposes of begetting more. In an agricultural view, land which we may render productive by cultivation, or the seed which we cast into the ground, and which, under favorable circumstances of situation, season, and culture, will multiply and return to us very often a hundred or a thousand fold, is capital. In a commercial view, capital is property beyond the wants of immediate subsistence, which you can invest in goods or articles of trade, and hold them in your possession, until under favorable circumstances you can sell, or exchange, and realize the profits of such adventure. Capital, in short, is money on hand, or the reserved profits of former labor, and speculation, or trade, which you can use for other and further purposes of trade and accumulation, and be able to wait its returns. But there is much other capital besides land or money. Every means of accumulation should be considered as so much capital. There is another agent in trade of equal power, as a means of accumulation, as money, and that is credit. This is often even far better than a moneyed capital. This will enable you, as far as you ought to desire it, to command the moneyed capital of other men, as if it were your own, and to use it for your benefit and theirs; and where it is based upon those substantial qualities of character, which form the only just and sure foundation of credit,—namely, truth, honor, industry, frugality, exactness, or punctuality,—it may be used with equal success and propriety as the instrument of accumulation, as the heaped up thousands which lay in the coffers of the most affluent.

Every thing in relation to matters of trade, and the pursuits of wealth, which is a means of accumulation, is capital. Now let us see, then, with what propriety it can be said of this young man of whom we have spoken, though he has no money at his entrance into life, that he has no capital; or rather, let us see what renders him an object of compassion.

He has youth, health, and ability. These all enable him to labor, and labor will command its reward. He has habits of frugality, which will lead to expend carefully, and lay up the surplus wages of labor,—that is, the surplus beyond his immediate necessities. He has the elements of a good education; this furnishes him the means of acquiring more knowledge, and knowledge is always power. He has an art or trade; and this gives him an immense advantage, and puts it in his power to apply his labor and faculties with far more advantage and profit than he could without. He is not the slave of any bad habits; his gains therefore are not insensibly creeping away from him. Above all, he has good character, this will give him credit. Habits of industry, frugality, and exactness, will secure, establish, and increase his credit to all the extent he should desire; and give him the command of the property of others. All this, then, is capital—capital of the best kind. A purely moneyed capital may pass away from him by a thousand contingencies; but this other capital, which I choose to call a moral capital, is under his own control, secure from all the fluctuations and vicissitudes of trade and business, and never can be taken from him without his own consent.

For a young man to be placed at once in the possession of a large moneyed capital at his setting out in business, though it may be highly gratifying to his vanity, is extremely hazardous to his virtue. I have known in such cases innumerable instances of deplorable failure and bankruptcy. The passion for speculation, over-trading, and extraordinary gains, to which they are excited by the possession of a large moneyed capital at setting out, leads men into a thousand risks, which they cannot encounter without extreme peril. On the other hand, those habits of care and caution, which small means, and gradual and moderate earnings beget, are a sure foundation of increase and security.

Large means and extensive speculations, where the possessor has had no lessons in a humbler sphere, nor been compelled by an early and stern necessity to proceed with the greatest caution, almost inevitably lead to habits of wasteful expenditure. "Many estates are spent in the getting." Wealth and accumulation depend as much upon saving as upon gaining.

To say of a young man, therefore, coming into life with health, strength, capacity for labor, a good education, a useful and respectable trade, habits of sobriety and frugality, and above all a good and unsullied character, that he has no capital, is a gross absurdity and error. He has the best of all capital—a moral capital; the noblest of all power—moral power; he has the most certain means of honest and honorable accumulation and fortune, and may be sure, under circumstances ordinarily propitious, to rise to that competency of influence, respect and general confidence, and that honorable measure of wealth and independence, which should fully satisfy a reasonable and virtuous ambition. H. C.

Cheering Prospect.

[*From the Franklin (Ky.) Farmer.*]

Our information from all quarters indicates that the coming agricultural year will be one of unprecedented activity and spirit in Kentucky. Improvement in the breeds of horses, cattle, mules, sheep and hogs; in all descriptions of seeds; in modes of culture; in feeding; and in agricultural implements, is now "all the rage." In the present year, our farmers will sow more and better seed and reap larger and richer harvests. There will be an improvement in the number and quality of all kinds of domestic animals. Why, some of our breeders are incurring considerable expense to improve the breeds of poultry, though Kentucky boasts the possession of the "game cocks" of creation. Our farmers will have better fences than formerly; and many well painted gates will be substituted for those annoying *inconveniencies*, "draw bars" and "slip gaps." The fence corners will be freed from weeds, and corn or grass will take the place of briars in the old fields. The logs, brush and undergrowth in the woodland pastures will be cleared out; and blue grass will be set in their place. Many of our Green river friends will abandon tobacco planting and adopt the grazing business instead. The root culture will be more generally and more energetically tried, and its adaptation to our soil and to the purpose of feeding stock, will be verified or disproven. The silk culture will receive wider attention, and many new mulberry orchards will be planted. The breeders will provide more house-room to protect their horses, cattle, and sheep from the inclemency of winter. There will probably be about twenty new agricultural societies organized, and a greater spirit of emulation manifested between the various societies, and the farmers themselves; and their sons will catch the same spirit, and lay the foundation for their future prosperity, in the enlightenment and information they will derive from the action of these societies. The house-wives too, will improve their domestic economy; the dairies will groan beneath the increased weight of butter and cheese; and the flocks of fowls in the barn-yard, will be doubled. The manure of the farms will be more carefully husbanded, and spread over the fields, instead of being wasted. We shall import no breadstuffs; but send abroad larger droves of live stock, and export greater quantities of corn, wheat, flour, tobacco, pickled pork, and beef, and bagging, and rope. And this acceleration of the agricultural pursuits, brought about by the joint influence of an increased spirit of improvement, with the belief that it is this interest which will disembarrass the country of its present pecuniary troubles, will also stimulate all the other branches of state industry. A higher moral influence will be attached to the labors of agriculture, and its salutary blessings will reach the whole community. The farmer will seek for more scientific knowledge; the standard of agricultural improvement will be elevated; practical truths, the ascertained results of well conducted experiments, will be applied in aid of their operations; they will read more, think more, write more, and in short, several thousand more of their names will be added to the subscription list of the Franklin Farmer.

Young Men's Department.

Hints to Young Farmers—No. VII.

INDOLENCE.

Beware of habits of indolence. They are the bane of happiness. Action is the first law of nature to animal creation, and even to some of the primary elements. Water, when long at rest, becomes putrid, and deleterious to animals and vegetables. Air is only fit for respiration while it is kept in motion. Most of the metals lose their lustre, and become corroded with rust, if not kept in constant use. So the human body, and noble mind, by inaction, become stagnant and corroded, and too often taint the moral atmosphere. Action—constant useful action, is the first requisite to health and usefulness. What matter of surprise should it be, then, to hear men—young men—whom fortune, honor, and happiness invite to action—to hear them complain that they *have nothing to do!*—and to see them dragging out lives of sloth and indolence, or hastening their termination, by intemperate indulgencies.

There is a strong propensity in young men to indulge in indolence, as soon as they feel confident they can live without labor, which should be met and conquered at the threshhold of manhood; for if then left unsubdued, it will take root, and, like the young oak, grow in strength with increase of years. The acorn is easily destroyed; but when the acorn has become a tree, it is difficult to uproot it. The propensity to indolence once mastered, and habits of industry well established, be they manual or mental—both are best conjoined—the current course of life is comparatively serene and prosperous. Systematic habits of industry and moral rectitude, are a far better portion to a young man, in the outfit of life, than a large fortune without these habits. The first seldom fail to elevate the possessor to wealth and respectability; the latter to sink him in both. There are more men of wealth and standing in society, who have become wholly so by their personal exertions, than there are that enjoy these distinctions by hereditary descent. There is perhaps no circumstance so propitious to success in life, as a resolute determination in the outset, to rely solely, under Providence, upon one's personal exertions—upon his industry and integirty—for fortune, fame and happiness. Such a resolution is oftener the result of necessity than of choice; but where, from either cause, it becomes the governing principle, it imparts a dignity and an independent bearing worthy of all praise, and impels to the most worthy actions. Who that has resolved, that he can and will provide for himself, would become the sycophant of power, the pander of vice, or the dependant upon the liberality or charity of others? The scramble for office, which annually distracts and demoralizes our country, owes more of its violence to the desire of men to live at the public expense, than from any cardinal difference in principle in the great body of the American people.

We will close this article with the following extract from Addison's Spectator, upon the subject which we have been discussing:—

"Indolence is a stream which flows slowly on, but yet undermines the foundation of every virtue. A vice of a more lively nature were a more desirable tyrant than this rust of the mind, which gives a tincture of its nature to every action of one's life. It were as little hazard to be lost in a storm, as to lie thus perpetually becalmed; and it is to no purpose to have within one the seeds of a thousand good qualities, if we want the vigor and resolution necessary for the exerting them. Death brings all persons back to an equality; and this image of it, this slumber of the mind, leaves no difference between the greatest genius and the meanest understanding. A faculty of doing things remarkably praise-worthy, thus concealed, is of no more use to the owner, than a heap of gold to the man who dares not use it.

"The time we live ought not to be computed by the number of years, but by the use that has been made of it; thus, it is not the extent of ground, but the yearly rent, which gives the value to the estate. Wretched and thoughtless creatures, in the only place where covetousness were a virtue, we turn prodigals! Nothing lies upon our hands with such uneasiness, nor have there been so may devices for any one thing, as to make it slide away imperceptibly and to no purpose. A shilling shall be hoarded up with care, whilst that which is above the price of an estate, is flung away with disregard and contempt."

Chemical Catechism.

We wish to infuse into the minds of our *young* readers, and we would hope to infuse into the minds, too, of those who do not claim to be young, so much taste for chemical knowledge, as shall induce them to study it, in hours of leisure, as a means of affording them a high intellectual gratification, and of contributing largely to their prosperity and usefulness in life.

Chemistry has become so essential in the successful management of all the arts of productive labor, embracing even the household arts, that its study is now made a branch of education in the common schools of France and of many of the German states. Judging from our own experience, a knowledge of many of its leading and more important principles, may be readily acquired by persons of common capacity; and the further one progresses in his knowledge of this science, the more it delights the mind, and the more it becomes subservient to the useful purposes of life. In the view of its great importance to society at large, we propose to publish in the Cultivator such parts of Parkes' Catechism of Chemistry, as we shall consider particularly beneficial to the generality of our readers. We extract the following from the author's essay on the utility of the study of chemistry, particularly to illustrate the advantages of this science in the business of agriculture.

"From the present state of chemical knowledge," says Parkes, "and the rapid improvements which have been made in our arts and manufactures, by the judicious application of its principles, it is become very desirable that every youth should be acquainted with its rudiments, and that chemistry should be made a regular branch of education in every seminary where the sciences are professedly taught and explained.

I have, therefore, imagined that I should render an acceptable service to society by showing the advantages which would arise from the acquisition of this kind of knowledge; especially as a large proportion of the community is not apprised of its real value.

The well informed people of France are so fully convinced of the importance of chemical knowledge, that chemistry has already become an essential part of education in their public schools. It shall be my business in this place to endeavor to demonstrate it to be of *equal* importance to the various classes of our countrymen, that the science should be cultivated with the same ardour in these kingdoms. The branch of education we recommend to your regard, has for its object every substance of the material world, and, therefore, is equally interesting to every civilized nation upon the earth.

Is your son born to opulence,—is he the heir to an extensive domain? make him an analytical chemist, and you enable him to appreciate the real value of his estate, and to turn every acre of it to the best account.

Chemistry will teach him also how to improve the *cultivated* parts of his estate; and by transporting and transposing the different soils, how each may be rendered more productive. The analysis of the soils will be followed by that of the waters which rise upon, or flow through, them; by which means he will discover those proper for irrigation; a practice, the value of which is sufficiently known to every good agriculturist.

Should he *occupy* his own estate, and become the cultivator of his own land, he must of necessity be a chemist, before he can be an economical farmer. It will be his concern not only to analyse the soils on the different parts of his farm, but the peat, the marl, the lime, and the other manures must be subjected to experiment, before he can avail himself of the advantages which might be derived from them, or before he can be certain of producing any particular effect. Besides, a knowledge of the first principles of chemistry will teach him when to use lime *hot* from the kiln, and when *slaked;* how to promote the putrefactive process in his composts, and at what period to check it, so as to prevent the fertilizing particles becoming effete, and of little value. A knowledge of the chemical properties of bodies will thus give a new character to the agriculturist, and render his employment rational and respectable.*

The various operations of nature, and the changes which take place in the several substances around us, are so much better understood by an attention to the laws of chemistry, that in every walk in life the chemist has a manifest advantage over his illiterate neighbor. And it may be remarked, that in case of failure or disappointment in any particular line of commercial manufacture, the scientific chemist has resources as various, as the productions of the country in which he lives, to which the uneducated man has no access.

Were parents aware of this truth, that sordid maxim, *primo vivere, deinde philosophari,* would not be heard: but every youth would be instructed in the first principles of natural philosophy and chemistry, and as the *means* for qualifying him for managing with advantage the concerns with which he might be entrusted. If "knowledge is power," surely the *love* of knowledge, and a taste for accurate investigation, are the most likely means of conducing him into that path which leads to opulence, respectability and rational enjoyment.

Moreover, it is the necessary consequence of an attention to this science, that it gives the habit of *investigation,* and lays the foundation of an ardent and inquiring mind. If a youth has been taught to receive nothing as true, but what is the result of *experiment,* he will be in little danger of ever being led away by the insidious arts of sophistry, or of having his mind bewildered by fanaticism or superstition. The knowledge of *facts* is what he has been taught to esteem; and no reasoning, however specious, will ever induce him to receive as true what appears incongruous, or cannot be recommended by demonstration or anology.

CHAPTER I.

INTRODUCTORY AND MISCELLANEOUS.

What *is chemistry?*

Chemistry is the science which enables us to discover the peculiar properties of all natural bodies, either in their simple or compound state.†

How do chemists examine the properties of bodies?

The chemical examination of bodies is in general effected by producing a change in the *nature* or *state* of the body under examination.†

By what means do chemists affect a change in the qualities or states of natural bodies?

This is generally effected by means of *heat,*§ or by the *mixture* of some other matter with the matter intended to be examined.

How does the application of heat and mixture enable chemists to examine the properties of bodies?

By these means we effect the *decomposition* of a compound body, and thus acquire a knowledge of the nature of its ingredients.

What is meant by decomposition?

In chemical language, decomposition means the art of dividing a body into its simple elements. Thus water may become decomposed, and reduced into oxygen and hydrogen, which are simple substances, incapable of further decomposition.

---

* Lavoisier cultivated 240 acres of land in La Vendée, on chemical principles, in order to set a good example to the farmers; and his mode of culture was attended with so much success, that he obtained a third more of crop than was procured by the usual method, and in nine years his annual produce was doubled.—*Lalande's Life of Lavoisier.*

† "Chemistry is that science which examines the constituent parts of bodies, with reference to their nature, proportions, and method of combination."—*Bergman's Essay on the usefulness of Chemistry, &c.* p. 4.

‡ To the eye many substances appear similar to other substances, though they possess different, and perhaps opposite, qualities; it therefore became necessary to discover the means of analysing these substances, and of ascertaining wherein their difference consists. These we find in chemical reagents.

It may, with few exceptions, be considered as an axiom in the science of which we are treating, that, *whenever chemical action takes place, a real change is produced in the substance operated upon, and that its identity is destroyed.* An example will place this in a clear point of view. If a little carbonate of lime (powdered chalk) be put into a glass of water, the chalk will sink to the bottom of the vessel. Though it should be mixed with the water, if left at rest it will soon subside. No chemical action has taken place, therefore the water and the carbonate of lime both remain unaltered. But if a small quantity of diluted sulphuric acid be added to a glass of chalk and water, a violent effervescence will take place the moment they come in contact with each other; a chemical union of the two substances will be the consequence of this chemical action; the identity of each substance will be destroyed; and sulphate of lime (a body entirely different from either of the substances employed) will be produced.

§ Heat has a tendency to separate the particles of all bodies from each other. Hence nothing is more necessary to effect the decomposition of many bodies than to apply heat, and collect the substances which are separated by that means. The mixture of two or more compounds, often produces a decomposition in each by means of chemical *affinity,* a property of bodies which will be more fully explained here after.

What are the different states of natural bodies?

The matter which constitutes this lower world is usually divided by philosophical writers, into four classes, viz: solid, liquid, aeriform, and imponderable.

What do you mean by a solid body?

Solidity is that quality of bodies whereby their parts cohere firmly, so as to receive impression.*

What are liquid substances?

Liquid substances are those whose parts do not firmly cohere, but readily yield to any impression, and have free motion amongst themselves.† They also assume, when in small masses, the spherical form, as may be observed in detached portions of mercury, and are incapable of being compressed into a smaller compass by mechanical force.

What are aeriform substances?

All elastic fluids, usually called vapors and gases, belong to this class of matter.

What substances are they which constitute the fourth class, or the imponderable bodies?

These are four only, viz: light, caloric, electricity, and magnetism. They are also sometimes denominated unconfinable, or etherial substances.

What occasions the difference which is observable in solid and liquid substances?

Liquid substances are merely solids converted into liquids by heat, a certain increase of which would convert any liquid into an elastic vapor, similar to that fluid body which surrounds the globe, and is described under the name of atmospheric air.

Why is the air called a fluid?

Because it flows like a fluid; because like a fluid it presses in every direction, and because light substances will swim in it.

What explanation do you give of bodies swimming in fluids?

All fluids upon which solids float are specifically heavier than those solids. This is an established law of nature. Thus a cork swims upon water, while a stone sinks in it.

Have you a clear idea of the cause which makes some substances sink, and others swim in the same fluid?

Those which swim are lighter, and those which sink are heavier, than that fluid:—thus in water, if a substance be heavier than a portion of water of *its own bulk*, it must sink.

What term is made use of to express the relative weight of bodies?

Specific gravity. Thus the specific gravity of one body may be much greater than that of another, though their absolute weights be the same.

How do you explain the difference in the specific gravity of different bodies?

When one body is larger, or takes up more room, than another of the same weight, the first is said to be *specifically* lighter than the other, and vice versa.

What definition do you give of the atmosphere which you speak of in connexion with this subject?

The atmosphere is that very light fluid‡ which surrounds us every where: it is the medium in which we live, and without which we could not exist.

What is the specific gravity of atmospheric air?

A pint measure of atmospheric air weighs nearly nine grains, whereas a pint measure of hydrogen gas weighs little more than half a grain. The same measure of pure water weighs upwards of one pound avoirdupois.

If the specific gravity of water be so much greater than that of atmospheric air, how is water retained in the atmosphere?

The water which is taken up by the atmosphere, is not in an aqueous state, but is converted into vapor by the matter of heat.

What is the immediate cause of the waters of the earth being thus evaporated?

As the rays of the sun warm the ground, a portion of caloric, or the matter of heat, combines with a portion of the water which has fallen upon the earth, and converts it into vapour.

But what causes the vapor to rise in the air?

If a cork be placed at the bottom of a basin of water, it rises immediately to the top, because it is specifically lighter than the water; so vapor rises in the air, because it is specifically lighter than the air.

What becomes of the water which thus evaporates from the earth?

It occupies the lower regions of the atmosphere, and is preserved there partly dissolved in air, and partly in the state of elastic vapor.

How is this vapor formed into clouds?

After it has remained some time in the atmosphere, it becomes in a measure condensed by causes unknown to us; and the particles of water of which it is composed unite, and form small hollow vesicles, which accumulate together and produce clouds.

What further changes take place in this aqueous vapor?

By the operation of causes which are also in a great measure unknown, the clouds after a time become further condensed, and are converted into water, which falls again upon the earth in the form of rain, hail, or snow.

What is the use of this constitution of nature?

This principle of evaporation is of great utility; it is subservient to many natural and artificial processes; and is of perpetual use to man in every occupation of life.

---

* Lavoisier has explained solidity thus: "The particles of all bodies," says he, "may be considered as subject to the action of two opposite powers, repulsion and attraction, between which they remain in equilibrio. So long as the attractive force remains stronger, the body must continue in a state of *solidity;* but if, on the contrary, heat has so far removed these particles from each other as to place them beyond the sphere of attraction, they lose the cohesion they before had for each other, and the body ceases to be solid."

† We have no reason to suppose that fluidity is an essential property of any liquid substance whatever; but rather that solidity is the natural state of all bodies; for we are able to reduce most substances to a state of fluidity by the combination of caloric. In general, bodies treated in this way, expand in all their dimensions, and the attraction of aggregation is so much weakened thereby, that the particles of the body slide over each other, and are put in motion by the slightest impulse. This is the only distinguishing character of fluidity that we are acquainted with. On the contrary, the greatest number of liquid substances take a *solid* form by reduction of temperature. Thus water congeals and forms ice Even the gases show this disposition. Chlorine, or oxymuriatic acid gas, becomes concrete, and crystallises at a temperature near to that at which water congeals. All the gaseous substances, when they have lost their elasticity, by forming certain combinations, are disposed to assume the solid state, if the temperature allows it. Ammoniacal gas and carbonic acid gas, become solid as soon as they enter into combination; and hydrogen gas, the most subtle of the ponderable elastic fluids, and fourteen times lighter than the air we breathe, forms, with oxygen gas, the water which becomes ice.

‡ Atmospheric air, like all other elastic fluids, yields to the slightest impulse, and is put in motion with the greatest ease; but it has not the power of penetrating many substances, like oils and some other fluids.

The facility and rapidity of the motion of atmospheric air, cannot be explained on any principle but its fluidity. Some of the winds move nearly at the rate of 4,000 feet in a minute. This great velocity was, doubtless, designed to produce some beneficial effects in the economy of nature, with which at present we are not acquainted. I come to this conclusion because I think we have sufficient grounds for believing that the Deity does nothing in vain.

"His wisdom guides the rushing winds,
Or tips the bolt with flame;
His goodness breathes in every breeze,
And warms in every beam."—Darwin.

Nothing so much aids us in learning, as writing down the things we wish to remember.—*Lat.*

THE CULTIVATOR:

A MONTHLY PUBLICATION, DEVOTED TO AGRICULTURE.

I KNOW OF NO PURSUIT IN WHICH MORE REAL AND IMPORTANT SERVICES CAN BE RENDERED TO ANY COUNTRY, THAN BY IMPROVING ITS AGRICULTURE.—*Wash.*

VOL. V. NO. 3, WASHINGTON-ST. ALBANY, N. Y. JUNE, 1838. NO. 4.

Conducted by J. BUEL, of Albany.

TERMS.—ONE DOLLAR per annum, to be paid in advance. Subscriptions to commence with a volume.

Special Agents.—L. & R. HILL, Richmond, Va.; BELL & ENTWISLE, Alexandria, D. C.; GIDEON B. SMITH, Baltimore, Md.; JUDAH DOBSON, bookseller, and D. LANDREITH, seedsman, Philadelphia; ISRAEL POST, booksellers, 88 Bowery, ALEX. SMITH, seedsman, P. WAKEMAN, office of the American Institute, Broadway, N. York; E. M. HOVEY, Merchants's Row, Boston; ALEX. WALSH, Lansingburgh, and WM. THORBURN, Albany, gratuitous agents. For general list of agents see No. 12, vol. iv.

The Cultivator is subject to common newspaper postage.

☞ Price of the published volumes, 50 cents per vol. stitched—the four volumes bound together, $2.75—bounded in two volumes, $3—the four vols. bound each separate, $3.25.

THE CULTIVATOR.

TO IMPROVE THE SOIL AND THE MIND.

Our three first Volumes.

☞ The second edition of vol. 1, and the first edition of the 2d and 3d vols. of the Cultivator, being about expended, and the demand for them continuing unabated, we are printing another edition, which will be completed with all despatch. Orders will, in the mean time, be received, and the volumes forwarded as soon as published. When completed, stitched and bound volumes will be forwarded to our agents in Boston, N. York, Philadelphia, Baltimore, Alexandria, &c.

☞ Our brethren of the type, who have borrowed any of the cuts belonging to the three first volumes, are requested to return them without delay.

☞ We treat our readers, in this number, with more than thirty interesting communications from correspondents, residing in different states, upon various branches of rural economy—and almost the whole of them are from practical, intelligent farmers. We doubt whether there is a periodical in this country, or any other, so well sustained by the voluntary contributions of practical farmers.

Mr. Coleman's Report.

We proceed to notice, according to promise, the first report of Mr. Coleman, on the agricultural survey of Massachusetts, embracing the county of Essex. The object of an agricultural survey, our readers we presume need not be told, is to describe a district of country, its soil, sources of fertility, products and farming operations—and whatever may be useful to the state, in promoting the improvement of agriculture, developing its sources of wealth, and multiplying the comforts and enjoyments of its inhabitants. The report before us is well calculated to promote these primary and legitimate objects of civil government. By a faithful detail of the best practices in husbandry—and many of those described in the report are well deserving of commendation,—the farmers of the state are enabled mutually to profit by the skill and improvements of each other,—each one may adopt whatever he finds excellent in the practice of others—and thus render the intelligence of all in a measure subservient to his individual profit. Besides, to quote from the report—

"If the survey results in no other good, it will present, I hope, in their true light, the motives which the children of Massachusetts have to stay at home. Her rewards to industry, enterprise, and good conduct, directed by intelligence, and under the guidance of temperance and prudence in the cultivation of her soil, are sufficient to satisfy every reasonable desire. Her social institutions and privileges are pre-eminent; and such as no new and unsubdued territory can expect to reach, under the most favorable circumstances, even in half a century.

"Filial reverence and affection are honorable traits of character, and among the highest duties of religion. Let the children of Massachusetts then honor and love their old mother. Her soil may be hard; but labor compels it to be bountiful. Her climate may be harsh; but it gives strength and elasticity to the muscles, and the brightness of its own stars to the mind. Her voice in winter may be sometimes hoarse, and her face wrinkled and frowning; but her children will not love her less for a sternness of discipline, by which she trains them up in habits of unremitting labor and self-dependence; and thus qualifies them to be the blessings and ornaments of their own community; the substantial pillars of the federal edifice; and the pioneers of learning, civilization, humanity, and religion in the boundless west."

The county of Essex lies upon the Atlantic border of Massachusetts, comprises an area of 360 square miles, and contains a population of more than 93,000. The surface is uneven and rocky, the soil of primitive formation, varying in its earthy ingredients from beach sand to stiff clay, though a gravelly loam, well adapted to husbandry, preponderates. There are extensive tracts of salt meadow on the coast, and large tracts of peaty swamp in the interior. The soil has been exhausted, like all the old settled districts of our country, by bad husbandry; and *no part of it*, says the report, *can be advantageously cultivated without manure.* The rural population are hardy, industrious, prudent, persevering, and of course prosperous. Tillage is very little practised, the main body of the land being devoted to pasturage and meadow. Much of the hay is carried to the towns, and manure brought back by the returning teams.—The tillage products are those common to the north, as grains, roots, &c. and considerable profits are drawn from the dairy. The quality of the soil is considered relatively good; but here, and in the yet unimpoverished west, it would be considered poor.

We will proceed to notice, in a summary way,

THE CROPS.

Grasses.—The following is given as the kinds and quantities sown: (I.) half a bushel of herds grass; (II.) half a bushel of herds grass and quarter of a pound red top; (III.) three pecks herds grass; (IV.) half a bushel herds grass, one-quarter pound red top, and one pint clover; (V.) half a bushel herds grass and half a pound red top; (VI.) one bushel herds grass, and sometimes two bushels. The herds grass here spoken of is the timothy of New-York and the south, and the red top is termed at the south herds grass. The average crop of grass seems to be from one and a half to two tons per acre, though the maximum product is given at three tons. The labor of cutting and curing an acre of grass, is rated at two days and a half of a man's labor; the average price of hay at the market, $16. The process of curing is not stated. The salt marshes yield from three-quarters to one and a quarter tons per acre—and the mean price of this hay may be stated at $10 per ton. In regard to saving herds grass (timothy) seed, the commissioner recommends, that the grass, when ripe enough, be cut when dry; allowed to lay one and a half days; tied in bundles, and set upright in a barn chamber, or on a scaffold, well ventilated, and where the scattering seed may be saved.

Indian corn is a staple crop; and the average expense of its culture, including manure, is given at about $40 per acre, a sum that would be appalling to a western or southern corn-grower; and yet the Essex farmer contrives to make a profit of $20 to $30 on an acre. The product is ordinarily from 40 to 70 bushels per acre, though it has been carried as high as 110 or 115 bushels. With some farmers this forms the first of a course of crops, and is planted upon sward; 2d year, corn or potatoes; 3d year, wheat, barley or oats, with grass seeds; then from three to four years in grass. Four to ten cords of manure to the acre are applied to the corn crop, which is hoed three times. The Pickwacket variety is deemed the earliest, though the Dutton has likewise ripened in favorable locations. The modes of culture and of harvesting are unfortunately omitted; though the commissioner recommends, that it be cultivated on a flat surface, without hills, in order that after the last hoeing *it may be laid down with grain and grass seeds*—a practice which we should decidedly condemn, as slovenly and particularly exhausting. Three highly exhausting crops, and all carried from the soil, in succession!! We like much better the following recommendation. The commissioner says—

"One of the most valuable improvements in the husbandry of the last twenty years, is that of planting this crop on an inverted green sward. The sward is completely turned over after vegetation has considerably advanced. The manure is applied on the *top* of the soil; and the field is then rolled in a thorough manner. The ground is next harrowed, and the corn planted either in drills or hills. When the roots of the corn pierce the sod, they find an abundant pabulum of decayed vegetable matter, equal, by as an exact calculation as can be made, to twelve tons upon an acre; and the crop is forced on, at the last of the season, when it particularly needs this stimulus and food, to great advantage."

As much as we commend this recommendation in general, and highly as we esteem the authority from which it emanates, we nevertheless venture to dissent from some of its positions. From the fact that only one pint of clover seed is sown in but one of the six modes of stocking with grass seeds, we presume the green sward recommended to be turned under "after vegetation is considerably advanced," is a tough old sward. If so, it will not be decomposed in season to afford food to the *young* corn crop, particularly without the aid of unfermented manures to accelerate fermentation and decomposition. Again: if the manure is unfermented, it will benefit the soil, ultimately, at least one-third more, if ploughed under, than if harrowed in. The recommendation will prove serviceable, in our opinion, only when applied to a *young* clover ley, and fermented manure.

Wheat.—The culture of this grain, "down east," is like rolling the stone up hill, except it be upon a limited scale, while the great secondary formation of the west is a competitor in the grain market. In 1827, we published in the New-England Farmer, our reasons for believing, that the primitive formation of New-England could never be a great wheat growing district, by reason of the deficiency of its soil in the salts of lime, and matters which afford azote, both found in wheat, and both indispensable in the soil to its successful culture; and we recommended the application of substances containing these essentials, as lime, bones, urine, horn, hair, night soil, the refuse of the tanner, tallow chandler, soap boiler, the offal of the butcher, the dung of fowls, soot, woollen rags, fish, &c. as proper means of giving to the soil this essential food to the wheat crop. And we remember that our friend Coleman rebuked us, and treated our views of the matter as visionary and absurd. We are happy to find that he has so far overcome his prejudice as to recommend lime, ground bones and soap-boiler's waste for wheat grounds, and to declare that some portion of the former is "deemed essential to success." This grain is however raised in Essex, on a small scale; but there is nothing mentioned of the mode of culture particularly worthy of notice. In regard to blight, Mr. Coleman states the following fact:

"Of two contiguous fields of wheat, similar in aspect, condition of soil, and kind of seed, which I visited this season, one was severely blighted, the other sound and perfect. The only difference ascertainable in the management of the two fields, was that one of the farmers, during the continuance of the heavy dews, and damp foggy weather, which occurred while the wheat was in flower, was careful every morning to sweep the dew from his wheat by passing a rope over it."

As the notice of the other farm crops contains nothing particularly notable, we merely make the following extract, describing a mode of preserving the potato. It would, however, be an improvement if the starch alone were retained, as the residue is of little use.

"Potatoes may be preserved by being rasped or ground to a pulp, and afterwards pressed with a heavy press, and then dried like cheese. Potato cakes of this sort have been found to keep perfectly sweet for years; and it is thought that ships bound on long voyages might find it advantageous to take their potatoes in this form."

Onions, carrots, beets and cabbages are cultivated profitably as garden crops for market. The produce of half an acre, in garden vegetables, is stated to have sold for $363.67.

The Dairy is on a limited scale, and little butter or cheese is sent to market. The commissioner states, that it requires a gallon of new milk to make a pound of cheese; that from two and a half to three gallons are required to make a pound of butter. "The cheese usually sells for eight or nine cents; the butter for 20 to 22. When cheese is worth nine cents, butter should be worth 22; the value of the milk then applied either way is the same. The skimmed milk and butter-milk, however, are of much more value for various domestic purposes, and for feeding swine, than the cheese whey. The labor of the manufacture is not very different. The care of the cheese, where it is kept through the season, is considerable. The yield of a cow in milk is stated generally at 350 gallons per year; of butter 87½, 116, 140 lbs.; of cheese I have not been able to obtain any return on which I could place any reliance." These data are worth remembering. Essex butter is stated to be inferior to the butter of Pennsylvania and New-York; and the commissioner hints at some of the causes of this difference, and suggests correctives.

The Sheep Husbandry is very limited, there being only about 6,000 sheep in the county. The commissioner thinks it may be profitably increased, in fattening wethers und rearing lambs for market. He estimates that the former may be fattened 12 weeks, upon hay and corn meal, for $2.54; and that they will then bring him $5.50 to $6.00—no great profit after paying $3.00 in the outset.

Beef.—The fattening of beef is extensively pursued, and the weight of some heavy cattle are recorded. Corn meal and potatoes, and in some cases apples, are the principal auxiliaries to hay, in the fattening process. A peck of meal and a bushel of potatoes are fed per day to a pair of fattening oxen.

Swine.—The Byfield breed, of some celebrity, originated in this county. The practice of cooking food for swine is recommended. "In an exact experiment," says the commissioner, "made by myself a few years since in this county, the largest gain ascertained was more than three pounds live weight; that is, 57 lbs. in 18 days. This was obtained on pure Indian hasty pudding."

Under the head of *Neat Cattle*, the report details the great product of several cows; but as this seems to have been owing to high feeding, and select individuals, rather than to particular breeds, we omit these details. The stock most prevalent is a mixed breed, termed "native stock," in which the Devon generally preponderates.

The chapter on *Manures* is valuable, particularly where, as in Essex, a farmer is content to pay $5.50 a cord for cow dung, and cart it four miles. Stable dung is in high repute, and sells at a very high price; yet there exists many other sources of fertility yet but partially brought into notice, which the commissioner names, as clover and other green crops, peat earth, sea ooze, sea drift, oyster and clam shells converted into lime, the refuse of the manufactories of almost every kind, leached ashes, and gypsum in the interior. Prof. Hitchcock's report cannot fail to enlighten the farmers of Essex on the interesting subject of manures.

We shall omit, for the present, any further notice of the report, and close this article with some suggestions of what we think would be manifest improvements in the husbandry of Essex. And,

First.—The root culture, particularly the ruta baga crop, might be beneficially extended, as a material for feeding and fattening farm stock, making manure and ameliorating the soil. Half a bushel of potatoes and half a peck of corn meal are stated to be a ration for a fattening bullock. Estimating the average potato crop at 160 bushels per acre, and of the corn at 40 bushels, an acre of each would give 320 rations to a fattening ox. Two bushels of ruta baga per diem, would be fully an equivalent for the half bushel of potatoes and half peck of corn meal, and we think would do more in the fattening process. An acre of ruta baga would give about as many rations as the acre of potatoes and acre of corn together, and could be cultivated and harvested at less expense than either; would not be so exhausting as the corn, and would add much, probably a third, to the manure. Thus, one half of the labor, and one half of the land might be saved.

Second.—By more generally alternating grain, grass and roots, for which the soil seems to be generally adapted, less manure would be required to keep up fertility, and the crops would unquestionably all be improved. We have treated this subject so fully in our article upon the new husbandry, that any further remarks are deemed unnecessary at present.

Third.—The culture of clover, with all small grain crops, as a means of *dividing and enriching the soil*, we think would certainly prove beneficial. The tap roots of this plant are admirably adapted to the amelioration of the soil; and supposing the ley to afford only half the vegetable matter furnished by old green sward, it would give six tons of manure to every acre which it is employed to fertilize. This, as manure is there valued, would be worth at least $20 the acre—a very liberal return for 60 or 70 cents expended in seed. And where gypsum exercises its magic powers, this would hardly fail to prove a reasonable result.

We shall take an early opportunity of resuming our notice of this report.

Geological Science applied to Agriculture.

We are obliged to our friend, the Rev. Mr. Coleman, for a copy of the last report of Prof. Hitchcock, being "*A re-examination of the Economical Geology of Massachusetts*;" or, in other words, geological science rendered subservient to the improvement of agriculture. It is a pamphlet of great interest, and we venture to class it among the most valuable works of the literature of American husbandry. It discusses with ability the sources of fertility, the causes of deterioration, and the means of renovating, our soils.—It describes the origin of soils; gives a classification of them, and a table of analysis; explains the properties of marls and lime,—the theory of their action upon soils, and the practical application of this theory; and it develops the fertilizing properties of marsh mud, muck sand, and other natural products, which abound in the state, and which may be brought to aid agricultural improvement. The work is a happy illustration of the vast benefit which science is capable of imparting to our husbandry.

We had occasion, in the second number of the current volume, to speak of the properties of *humus*, otherwise *ulmin*, or vegetable extract, the great source of fertility to soils. In the report before us, this indispensable food of vegetables is denominated *geine*, a name first given to it by Barzelius. The following extracts, which are in the language of Dr. Dana, of Lowell, will enlighten our readers further on this subject, and serve to demonstrate, that all animal and vegetable substances are convertible into the food of plants;—that they constitute the proper food of plants;—that all organic matter may be again transmuted into organic matter;—and that the alkalies, salts and atmospheric air, with which dung more or less abounds, are indispensable agents in converting dead into living organic matter—into grains, grasses, and roots,

"By *geine*," says Dr. Dana, "I mean all the decomposed organic matter of the soil. It results chiefly from vegetable decomposition; animal substances contain a similar compound containing azote." * * "Geine exists in two states: soluble and insoluble: soluble both in water and in alkali, in alcohol and in acids. The immediate result of recent decomposition of vegetable fibre is abundantly soluble in water. It is what is called solution of vegetable extract. Air converts this soluble into *solid* geine,* *still partially soluble in water*, wholly soluble in alkali. Insoluble geine is the result of the decomposition of solid geine; but this insoluble geine, by the long continued action of air and moisture, is again so altered as to become soluble. It is speedily converted, by the action of lime, into soluble geine.†—Soluble geine acts neither as alkali or acid. *It is converted into a substance having acid properties by the action of alkali*, and in this state combines with earths, alkalies and oxides, forming neutral salts, which may be termed *geates*. These are more soluble in water than solid geine; especially when they are first formed.—Their solubility in cold water is as follows: beginning with the easiest, magnesia—lime, manganese, peroxide of iron—(it does not unite with protoxide of iron,) alumina, baryta. The geates of the alkaline earths are decomposed by carbonated alkali. The geates of alumina and of metallic oxides are soluble in caustic or carbonated alkali without decomposition. The geates of the alkaline earths, by the action of the carbonic acid of the air, become *super-geates*, always more soluble than neutral salts. Soluble geine, therefore, includes the watery solution—the solid extract caused by the action of the air on the solution, and the combinations of this with alkalies, earths and oxides. Insoluble geine includes all the other forms of this substance."

"Soluble geine is the food of plants. Insoluble geine becomes food by air and moisture, Hence the reason and result of tillage. Hence the reason of employing pearlash to separate soluble and insoluble geine in analysis."

"These are facts. Will they not lead us to a rational account of the use of clay, lime, ashes and spent ley? Will they not account for the superiority of unfermented over fermented dung in some cases?

"Geine forms the basis of all the nourishing parts of vegetable manures. The relations of soils to heat and moisture depend chiefly on geine. It is in fact, under its three states of "vegetable extract, geine and carbonaceous mould," the principle which gives fertility to soils long after the action of common manure has ceased. In these three states it is essentially the same. Of all the problems to be solved by agricultural chemistry, none is of so great practical importance as the determination of the quantity of soluble and insoluble geine in soils. This is a question of much higher importance than the nature and proportion of the earthy constituents and soluble salts of soils. It lies at the foundation of all successful cultivation. Its importance has not been so much overlooked as undervalued. Hence, on this point the least light has been reflected from the labors of Davy and Chaptal. It needs but a glance at any analysis of soils, to see that fertility depends not on the proportion of the earthy ingredients. Among the few facts best established in chemical agriculture, are these: that a soil, whose earthy part is composed wholly, or chiefly, of one earth; or any soil, with excess of salts, is always barren; and that plants grow equally well in all soils, destitute of *geine*, up to the period of fructification,—failing of geine, the fruit fails, the plant dies. Earths, and salts, and geine, constitute, then, all that is essential; and soils will be fertile, in proportion as the last is mixed with the first. *The earths are the plates, the salts the seasoning, and the geine the food of plants*. The salts can be varied but very little in their proportions, without injury. The earths admit of wide variety in their nature and proportions. I would resolve all into 'granitic sand;' by which I mean the finely divided, almost impalpable mixture of the detritus of granite, gneiss, mica slate, sienite and argillite; the last giving by analysis a compound very similar to the former. When we look at the analysis of vegetables, we find these inorganic principles constant constituents—silica, lime, magnesia, oxide of iron, potash, soda, and sulphuric and phosphoric acids. Hence these will be found constituents of all soils. The phosphates have been overlooked from the known difficulty of detecting phosphoric acid. Phosphate of lime is so easily soluble when combined with mucilage or gelantine, that it is among the first principles of soils exhausted.—Doubtless the good effects, the lasting effects, of bone manure, depend more on the phosphate of lime, than on its animal portion. Though the same plants growing in different soils are found to yield variable quantities of the *salts* and earthy compounds; yet I believe, that accurate analysis will show, that similar parts of the same species, at the same age, always contain the inorganic principles above named, when grown in soils naturally arising from the decomposition of granitic rocks. These inorganic substances will be found not only in constant quantity, but always in definite proportion to the vegetable portion of each plant. The effect of cultivation may depend, therefore, much more on the introduction of *salts* than has generally been supposed. The *salts* introduce new breeds. So long as the salts and the earths exist in the soil, so long will they form voltaic batteries with the roots of growing plants, by which the 'granitic sand' is decomposed, and the nascent earths, in this state readily soluble, are taken up by the absorbents of the roots, always a living, never a mechanical operation. Hence, so long as the soil is *granitic*, using the term as above defined, so long is it as good as on the day of its deposition; *salts* and *geine* may vary, and must be modified by cultivation. The universal diffusion of granitic diluvium will always afford enough of the earthy ingredients. The fertile character of soils, I presume, will not be found dependent on any particular rock formation on which it reposes. Modified they may be, to a certain extent, by peculiar formations; but all our granitic rocks afford, when decomposed, all those inorganic principles which plants demand. This is so true, that on this point the farmer already knows all that chemistry can teach him. Clay and sand every one knows: a soil too sandy, too clayey, may be modified by mixture; but the best possible mixture does not give fertility. That depends on salts and geine, [manures.] If these views are correct, the few properties of geine which I have mentioned will lead us at once to a simple and accurate mode of analyzing soils—a mode which determines at once the value of a soil, from its quantity of soluble and insoluble vegetable nutriment,—a mode, requiring no array of apparatus, nor delicate experimental test,—one, which the country gentleman may apply with very great accuracy; and, with a little modification, perfectly within the reach of any man who can drive a team or hold a plough."

Professor Hitchcock gives the analysis of 125 specimens of soils, with the quantity of soluble and insoluble geine, salts of lime, and granitic sand found in each, and also the absorbent power of each. Only seven of these specimens, gave indications, on analysis, of the presence of carbonate of lime, although several of them came from limestone districts. After a detailed account of the examination of soils, Professor Hitchcock adopts the following

GENERAL CONCLUSIONS.

"Without stopping," says the report, "to notice some things of minor importance, I will state at once the most important conclusions that have forced themselves upon my mind, from all my examinations and analyses of our soils, respecting their deficiencies and the means of remedying them.

"*First, the grand desideratum in our soils is calcareous matter; that is, carbonate of lime.*

"*The second desideratum is, an additional quantity of geine; that is, a larger supply of the food of plants.*

"*Hence, thirdly, the great object of the agricultural chemist should be, to discover and bring to light new supplies of both these substances.*

"The discovery of either of them would, indeed, be of no small value; but it is a principle that never ought to be lost sight of, that an additional quantity of lime in the soil, will commonly require an additional quantity of organic matter, [manure] and an increase of the latter will be far more serviceable, if attended by an increase of the former.

"These fundamental principles and conclusions I have kept in view continually; and will now proceed to show with what success I have searched for new sources of lime and geine. I shall begin with the former as the most important, because the farmer already possesses the means of increasing the quantity of his manure, but not of obtaining calcareous matter; for, with the exception of Berkshire county, Massachusetts is very deficient in limestone."

We shall resume, hereafter, the subject of this report, and at least enumerate the fertilizing materials of which it takes cognizance.

The North and the South.

The remark is often made in the southern journals, that the north is half a century in advance of them in agricultural and rural improvement. From what little observation we have been able to make, we are inclined to think there is some truth in the remark, though there certainly are in the south many individual and highly honorable exceptions. The exhausting system of continual cropping, has been so long persisted in at the south,* that perhaps millions of acres have become so impoverished as to be thrown into commons—and turned over to nature to renovate their fertility, by a slow growth of cedars, pines and chinquepins. We confess that in some districts of the north our condition is but little better; but in general we have long since commenced a better system, which is now going on with spirit. By clover and plaster, alternating crops, root culture, draining, increase of farm stock, and economy in saving and applying manures, we have renovated much of our once exhausted, and reclaimed much of our waste lands, and rendered them highly productive and profitable. Yet at the north the work of improvement is but begun.

---

* Hence the impropriety of summer yarding manures.

† Hence the use of lime in soils abounding in inert vegetable matters, or insoluble geine.

There has, besides, been less attention paid to the comforts and embellishments of HOME in the south than in the north. The buildings, particularly those denominated out-buildings, court-yards and gardens, receive less attention at the south than they do at the north. A traveller, in describing this contrast to us, remarked, that in one case the owner seemed to be AT HOME—in the other, NOT AT HOME—that one, like the bee, appeared to be gathering the sweets of life from a diversity of rural and interesting objects, as it were in detail, while the other was looking for enjoyment principally in the products of his broad-spread fields, and by wholesale.

There is evidently, however, a difference, in favor of the north, in the manner of managing farm lands, principally, we believe, growing out of education and habit. If there is not more science, there is at least more practical knowledge in husbandry at the north than at the south; and these are both essential to an improved state of husbandry. Poor Richard says,

> "He that by the plough would thrive,
> "Himself must either *hold* or *drive*."

The northern farmer generally does one or both, either from choice or necessity. He is the manager, if not the laborer. It is too often the case in the south, we fear, that the planter, personally, neither *holds* nor *drives*. Hence the mismanagement of his land and the deterioration of his soil. Where labor is held to be menial, the principles upon which it ought to be conducted are often overlooked. A knowledge of these principles, acquired in youth, with the supervision of their application in practice, would soon impart a relish for rural pursuits, increase their profits, and greatly improve the general appearance of the country. The sentiment of Washington, that there is "no pursuit, in which more real and important service can be rendered to any country, than by improving its agriculture," backed, as it was, by his efforts to improve his own and the agriculture of his country, should be a sufficient stimulus to the generous minded and chivalrous young gentlemen of the south to imitate his illustrious example,—to study the principles of the parent art, and to understand so much of its practical routine, as to be able to direct its labors with skill and profit. We recommend this course, not only as a source of profit, but of high intellectual enjoyment and substantial comfort. An education in a practical and theoretical school of agriculture, at the north, would enable the young gentlemen of the south to manage their estates far better than they are now managed, without abstracting from their respectability, their rational enjoyments, or their usefulness to society. Such schools we hope yet to see in successful operation among us, and to see their blessings, agricultural, moral and political, diffused into every portion of the Union, in despite of the fatuitous policy, which seems yet to prevail, in regard to this matter, in our halls of legislation.

The Grain Worm.

The legislature not having offered any reward for the discovery of a preventive to the destructive ravages of this insect, our offer of a premium of FIFTY DOLLARS for such discovery remains in force. The editors of the Yankee Farmer have offered a like reward of THIRTY DOLLARS. What gentleman will authorize us to add 50, 40, 30, 20, or 10 dollars to the reward? The evil is one of great magnitude, involving the interests, more or less, of every member of the community. If the reward should be justly claimed, millions will be saved to the state. If it is not claimed, no one will be the loser. We invite millers, merchants, land-owners, farmers——all——to weigh the matter deliberately, and permit us to register their names as contributors to this fund, in such sums as they are willing to give.

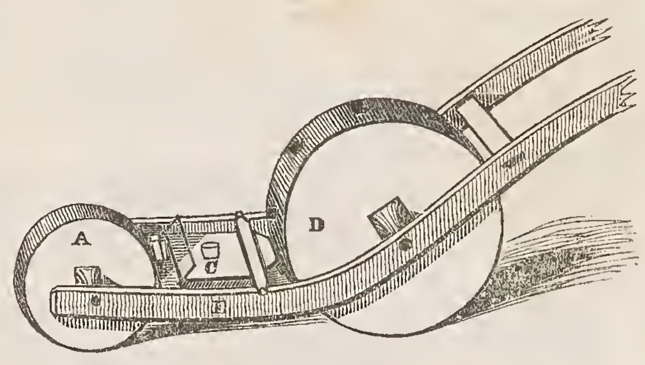
Small's Plough.

We have seen this plough in operation, under the management of two excellent ploughmen, who fully concur with us in opinion, that it is constructed on an excellent model, that it performs its work fast and well, promises to be durable, is of easy draught, and, what is a matter of some consideration, is moderate in price,—it being sold at the factory, in Argyle, Washington county, at $8, and in Albany at $9—two extra points for $1 additional. It has been brought to its present improved state by Mr. Wm. Small, an experienced and intelligent Scotch ploughman. It is for sale by W. Thorburn and J. H. Loucks, in Albany, and by Mr. Small in Argyle. We can with confidence recommend it as an excellent implement.

Bushnel's Drill Barrow.

We noticed in our August No. of last year a rough model of this implement, exhibited before the viewing committee of the State Society, described its parts, and pointed out some of its advantages. Mr. Bushnel, we are glad to learn, has built many drill barrows after the model exhibited, and finds a ready sale for them. He has placed some in the hands of our neighbor Thorburn, for sale, at $6, and sells them at his shop at $5. We shall speak more particularly of this implement after we have given it a thorough trial, which we design to do, having one in our possession; yet we doubt not but its operation will prove satisfactory. Address S. H. Bushnel, Sheffield, Mass. To those unacquainted with the value of the drill barrow, in sowing seeds in row culture, it may not be amiss to observe, that with one a man may sow three or four acres per day, of ruta baga or other seeds.

[Fig. No. 34.]



A. forward wheel, which smooths and pulverizes the surface. *B. B.* the shafts and handles. *C.* the hopper, between which and the forward wheel is the coulter, not seen in the view; and behind which is the brush or rake that covers the seed. *D.* the after wheel, which presses the earth upon the seed.

The Grain Crop.

We are gratified in the news from the south and the west, that winter grain generally promises a good crop, where it is not likely to be visited by the grain worm; but this insect enemy may be expected to reach Westchester on the south, and the valley of Genesee west, the coming summer. And it is no less gratifying to learn, by a gentleman from the northern part of Vermont, where the worm seems first to have made its appearance on our continent, some eight or ten years ago, that this scourge is no longer seen in those parts. We hope that in neither case will our information prove illusory.

"Half Farmers."

There is truth in the remark, that lumbermen and fishermen make poor farmers. These employments take men from home when they are most wanted on their farms; farming becomes with them a secondary business; and, besides, their constitutions become impaired, and their habits unsettled, by these employments. Farming will not thrive generally in any district where fish or lumber constitute staples of trade. And we have fancied, and it may have been nothing but fancy, that in passing out of New-York, where the farmers are generally *all farmer*, into New-England, that there was a marked falling off in the management of farms—which we ascribed to the proneness of our Yankee brethren to be "*jacks at all trades*," which, as the adage teaches, renders them "*good at none*." The truth is, there is hardly a business in life upon which a man's *whole* time, talent and capital becomes so *progressively* productive as that of farming—nor in which at least the two first are so essential to eminent profit and success. A correspondent, who dates at Susquehanna, N. Y. complains bitterly of the wretched state of husbandry in his vicinage, not owing, he says, to the infertility of the soil, which is good, but to the lumbering business, which, while it enriches a few, so impoverishes the many "half farmers," that they are barely able, with the greatest exertions, to "make both ends meet." We do not know how the evil is to be remedied, unless these "half farmers" will quit the water, take the Cultivator, and study and follow its maxims, which will not fail to make them

> "Healthy, wealthy and wise,"

as poor Richard says. Then may our correspondent see his hopes realized.

What has the Legislature done for Agriculture?

From the indications given in our March and April numbers, many persons, as well as ourselves, were led to hope and expect, that our legislature would have made a just, if not a generous appropriation, in aid of the improvement of our agriculture,—and they were lauded abroad for the liberal provisions which they were expected to make in its behalf. But alas! the session has gone by, and nothing has been done, and hardly attempted to be done, in furtherance of this great branch of industry. A bill was reported in assembly, by Mr. Allen, and some discussion had upon its merits; but no question was taken which fairly tested the sense of the house. Indeed, such was the boyish scramble for popularity, by shortening the session, and such the urgency of individual and corporate claims upon their attention, that the representatives had but little time to devote to the humble claims of agriculture. There were many thousand dollars appropriated to literary schools, and some millions to aid incorporated companies, but not a cent in direct aid of the great body of the people who follow the business of farming. And what is the most astonishing, and will hardly be believed by the coming generation, the farmers in the legislature were mostly disinclined to make the anticipated appropriations! We ardently hope, that the sons of *such* farmers will possess more wisdom than their fathers, and that they will ere long occupy their places in our legislative halls.

Agricultural Implements.

We mention, for the benefit of our subscribers in Virginia and the neighboring states, that an extensive manufactory of agricultural implements has been sometime in operation at Richmond, Va., under the direction of Jabez Parker; and that the implements furnished from his shop, as threshing machines, straw cutters and corn shellers, are, according to the Richmond Enquirer, particularly excellent. Labor-saving machines, like those above named, as well as cultivators, drill barrows, horse rakes, &c. add much to the profits of farm labor, and are becoming almost indispensable in spirited and profitable husbandry.

Agricultural School.

A highly respected correspondent, who makes farming his pleasure and sole business, and who, by his example, is enlightening and benefitting those around him,—expresses his disappointment and mortification, at the failure of our legislature to adopt an enlightened and liberal policy in regard to the improvement of our agriculture. In a letter to us, he says—

"I presume we went into the field too soon for the harvest. The time is not yet come—the Cultivator has not done its perfect work; but I feel assured it will do it in time; and until then, it will be to little purpose to force on a people a benefit they do not appreciate or wish.

"Any thing within the compass of individual enterprise and philanthropy, may still succeed, and be carried through, to the benefit of the few who have learnt the value of information and acquirements, and already suspect that there is science in agriculture. I look to the establishment of agricultural schools as belonging to an earlier state of things than agricultural exhibitions.—To him who has made no advance, an agricultural exhibition, nine times in ten, is a source of mortification, and a wounding of self-love; but a school will awaken the spirit of improvement; and a few young men going forth from such an establishment, will be like a little leaven in the inert mass. I hope its consideration may be early resumed. At this moment, how many young men of education, could they enter such a school, if only for a year or two, would put their hands to the plough, as the auspicious means of providing a moderate living for the future."

Massachusetts Premiums.

The trustees of the Massachusetts agricultural society have offered the following premiums for the best cultivated farms in that state, of not less than seventy acres, exclusive of wood land, regard being had to the quantity of produce, the manner and expense of cultivation, and the general appearance of the farm:

For the first best farm,	$200
For the second best,	175
For the third best,	150
For the fourth best,	75

All the minutia of soil, culture, stock, manures, product, &c. are required to be stated, and the farms are to be inspected by one of the trustees or an agent. The form of application, as prescribed, is this:

"To Benj. Guild, Esq. Boston.

"Sir—The subscriber, living in the town of —— hereby makes known his intention of applying for a premium for the best farm, and offers the same for inspection."

---

* A letter just received, and now before us, dated Eastville, Va. says—"*All* our cleared lands are divided into two equal fields, one of which is planted in Indian corn, and the other sown with oats alternately, every year, except some manured lots, which are appropriated to sweet potatoes, on which all the manure is put which can be had from the most negligent and slovenly husbandry. I presume an average crop of maize is from six to seven bushels to the acre, and from five to seven bushels of oats." It is no wonder, that under *such* a system of farming, lands should soon be worn out.

Teazles

Are extensively used in our woollen manufactories. They are biennial—that is, it requires two seasons to bring the crop to maturity. They have been partially grown among us; and, under favorable circumstances, are a highly profitable crop. The following communication, copied from the Silk Grower, describes the mode of culture, and gives data as to the profits of the crop; which, allowing one half for leeway, it will be seen, is still far greater than we are accustomed to realize from ordinary farm crops.

"The soil should be rich, not sandy, but loamy; I begin to sow in the spring *not* expecting a crop till a year from next fall; in order that I may have an annual crop I adopt the following method: I sow two rows about 16 inches apart, leaving the plants about 12 inches apart; if they are too thick, I transplant them the next spring. I then leave a space of four feet for the next year's crop, which is manured by use of a hand cart. I hoe the plants well two or three times. The same piece of land, if well cultivated, will bear a good crop for several years. To make it still more profitable I sow English turnip seed on the vacant parts; in this way I raise about 200 bushels of good turnips. It does not cost any more to raise teasles than it does corn; there is no danger of the frost injuring them. I raise from 150,000 to 200,000 to the acre; they are worth this year $1.50 per thousand; some years they are worth $3 a thousand. I raised two acres of them this year; at the present prices the profit per acre is from $225 to $300; when they command $3 per thousand, the profit is from $450 to $600, which is giving five or six fold more profit than can possibly be made from corn. I generally *give* away the seed."

We add to the above, from Loudon, that the crop is taken, except the plants to be preserved for seed, about July of the second year of growth, *when the blossoms begin to fall from the top*. It is the best method to have the heads cut as they become fit, at three different times, at the distance of ten days or a fortnight from each other. The heads are cut with a knife, contrived for the purpose, with a short blade and a string attached to the haft. A pair of strong gloves is likewise necessary. The ripe heads are cut with a stem of about nine inches, tied in handfulls, put in a dry shed, and exposed to the sun, when the weather is fair, until they become perfectly dry.—When tough, and of a bright color, they are sorted into three kinds, termed kings, middlings and scrubs, and are then fit for market. *To save seed*, leave the requisite number of plants uncropped—select, when ripe, the largest and terminating heads, and thrash them with a flail.

German Agriculture.

We know very little of the details of German agriculture; but we have read quotations from the agricultural works of Von Thaer and Sprengel;* and we have learnt from travellers, enough to desire to become better acquainted with her rural practices, conscious that they would afford valuable data for guidance in American husbandry. We have been induced to refer to this subject, by the receipt of a printed memorial of Charles Lewis Fleischmann, a graduate of the royal agricultural school of Bavaria, on the subject of improving the agriculture of this country, and printed by order of congress. We make the following extracts from this memorial, to show the advances which are making in Europe in the improvement of agriculture and of the agriculturist, by the establishment of schools of practical and scientific agriculture, and by agricultural societies and agricultural journals—and in the hope, too, that these extracts will awaken in our statesmen and our citizens generally, a better feeling—and induce a more liberal and enlightened policy—towards that great branch of productive labor, which is at once the basis of our prosperity and the palladium of our independence.

"Agriculture has made, within the last twenty years, throughout all Europe, and even in Asiatic Russia, a very successful progress. The advantage and necessity of diffusing this useful science were felt especially in Germany; there, different plans were suggested and adopted to accomplish it; agricultural societies were formed, and privileged by the governments; the divers experiments were published through journals, and prizes distributed for inventions and improvements: but all that had not the expected effect. The practical farmer, uneducated and full of prejudice, was not able to understand the principles of the new system; the man of scientific education had no experience and knowledge of applying science to practice properly; and so the most brilliant result of one improved branch was the cause of the ruin of other branches, by paying too much attention to a pet branch, and neglecting, for its sake, the whole system. This partial experimenting caused more injury than real good. Lastly, in order to diffuse the science of agriculture properly, so that every branch would affect all others advantageously, and the whole system of this so important science become perfected, it was found necessary to erect schools, and educate young men scientifically and practically. Such schools were established on large properly-conducted farms, where all the sciences were taught connected with agriculture, illustrating the practical manipulations in the field, barns, stables, &c., together with the use of all the implements and machines, as well as all the minutest branches of husbandry.

"The great *A. Thaer* brought the science of agriculture to a system, and *Burger's Lehrbuch* [manual] of agriculture was the general guide for the pupil.

"Within the short period of six years, the influence of these institutions was felt throughout the whole country. The young scientific agriculturist was employed as domain inspector, or superintendent; many applied the new science to their own estates.

"A proper rotation of crops having been introduced, with regard to the circumstances and localities, the stock increased and progressed far towards perfection; the land was ameliorated, and every part of husbandry improved; their ignorant and prejudiced neighbors became convinced; they began to imitate, and to read; and, in a short space of time, the old system was abandoned, and the farmer soon saw and realized the advantage of the science of agriculture.

"When land is rich, cheap and plenty, farming seems to be easy; but when land is poor, scarce and valuable, then the question, *'how to gain the highest clear profit under any circumstance, and to improve land and stock,'* becomes difficult.

"In general, poor soil can only be improved by animal manure. To produce animal manure cheap, and in sufficient quantity, is the most important subject of investigation for an agriculturist. It has an influence upon every branch of agriculture; from the quantity of manure necessary depends the rotation of crops, so as to produce, with least quantity of manure, the greatest quantity of food and grain, and to ameliorate the ground. From the quantity and kind of manure necessary depends the number of the domestic animals that must be kept on a given quantity of land.

"Manure has to be the first consideration in taking up poor land, and from that point start all other investigations. The cheap production of manure influences cheap production of food and grain, and is the result of high profit.

"The moment is arrived when agriculture can be brought to the highest perfection.

"Chemistry has made great progress, and has been especially treated in reference to agriculture.

"The scientific agriculturist is enabled now to make a sure and correct judgment on the experiment of the practical farmer. He can now with certainty, in advance, predict the result of every agricultural operation, and has to place no dependence on good luck, and leaves nothing to chance; neither is it necessary for him to lose time and profit, by making experiments on a small scale.

"Agricultural chemistry detects and discovers especially the secret of the life of plants, and it is therefore a necessary science for all who occupy themselves to gain products from the field, meadows, &c.

"Agricultural chemistry is that science which shows the influence of rotation and the richness of soils; it is the science which teaches how to ascertain the relative value of food, grain, straw; the value of the different kinds of manure; and to ascertain with certain success the proper food for animals, the proper kind of soil for plants, and the best manure for them.

"*Charles Sprengel* occupied himself during 20 years to apply chemistry to agriculture. He was guided by the essays of the most celebrated chemists, and has succeeded in giving the scientific world a systematical book, in which the principles of chemistry are illustrated through examples, and the theories of his doctrine applied to practice.

"Germany has many agricultural schools of great perfection; agricultural societies and journals every where; and the nobility have taken it as a pride to improve their domains, and publish their progress.

"Germany possesses eminent schools of veterinary, and distributes prizes every year for treatises on agriculture.

"Germany brings every year at least 1,000 volumes more books into market than any other nation; and the most of those books are on sciences adapted to practice. And yet how little do we know about their philosophical and scientifical transactions? And why? The German language is very little understood among a population of *English* origin.

"The first step in every undertaking is the most difficult. This difficult step this country has already taken—which is, having discovered the utility of diffusing the agricultural science. The next step is to establish agricultural schools, where that science can be taught theoretically as well as practically.

"In such agricultural schools should be taught pure mathematics, such as arithmetic and geometry; the practical application of it in mensuration, surveying, mechanics, hydraulics, hydrostatics, architecture, civil engineering, &c.; natural philosophy; chemistry, and its application to practice; zoology, botany, mineralogy, and geology; drawing; the veterinary art; and agriculture in all its branches.

"The pupils should be divided into three classes.

"The *first class* should consist of those who only want to become acquainted with the practical management of peculiar branches; for example, wool-growers. These should be paid for their services, and have a lecture every evening, *gratis;* and after serving one year or more, they could be qualified to superintend similar branches.

"*Second class,* those who desire to become acquainted with the practical management of all branches in agriculture, and the necessary rudiments of the sciences.—Terms two years, from 16 years of age and upwards.

"*Third class,* those who wish to become entirely versed in the sciences of agriculture, so as to be qualified for professorships. Term, three years.

"To illustrate the theory by practice, there should be a pattern-farm of about one thousand acres, so as to show an extensive manipulation. The farm should be conducted with the view of gaining the highest profit, so as to prove the utility and truth of the science of agriculture. A few acres of land only ought to be employed for experiments.

"The veterinary art, which teaches the external forms, as well as the internal construction and economy of the domestic animals, the proper management of them, the causes and treatment of their diseases, and the art of shoeing them, is a most important branch of an agricultural school.

"Agricultural schools of the preceding description, in which the most important sciences for a practical life are taught, would be the nursery of valuable citizens for a republic. Such men would honor and benefit the whole country; encourage and promote commerce, manufactures and internal improvement; carry public prosperity to the highest point, and increase the happiness of society."

Geological Survey of Ohio.

We have been politely furnished, by the author, with a copy of the first report on the geological survey of Ohio, by Prof. Mather. It announces the important fact, that 1,200 square miles of that state are underlaid by coal, and 5,000, by workable beds of this valuable mineral. This fact is of the utmost importance to the future welfare of that state, and of other states connected with it by water communication.—It not only ensures a permanent supply of fuel, when the native forest shall disappear, an event with which a large portion of that state is threatened from the fertility of soil, and the rapid increase of its population,—but will be all important in working the iron and the lead, with which the state is believed to abound, and in carrying on other extensive and needful manufacturing establishments. The coal formation constitutes the principal mass of the southeast portion of the state, reposes in beds of a mean thickness of six feet, lying nearly horizontal, and the coal beds are favorably situated for working, as they are found in the hills and ravines, where they can be drained with little expense, and without deep shafts and expensive machinery. Limestone is the prevailing rock, and underlays a large portion of the state. It is accessible, and well adapted to the purposes for which it is elsewhere employed. Sand stone most predominates in the coal region, and is found suitable for the most permanent works, and some answers well for grind-stones. Salt and other mineral springs are numerous. Buhr stone is found in abundance on the southern border of the state, and the value of mill stones annually manufactured from it is stated to amount to 20,000 dolls. We shall close our brief notice of this report with the following extract on

"SOILS.

"The soils of Ohio are so rich, that many would suppose them scarcely capable of being rendered more productive. Art, however, is capable of improving many of them, so much as to double their produce.

"As we are almost exclusively dependent upon the soil for those articles of food and raiment necessary to the supply of our animal wants, and, as the annual products of the soil form the largest item in the increasing wealth of the state, it is deemed expedient to consider this subject with some attention. All the richest and most densely populated agricultural districts, are on the transition, secondary, tertiary and alluvial formations. Soils, with the exception of those resulting from alluvial *depositions*, are derived from the disintegration and decomposition of the subjacent materials, and they depend, in a great degree, for their qualities, upon their mechanical and chemical constitution; hence, the geology of a territory is a necessary prerequisite in estimating the agricultural characters and value of its soils.

The variations in the productiveness of soils are due to two general causes—viz.

1st. The mechanical texture of soils.

2d. Their chemical composition.

1st. The *texture* of a soil is a character of more importance than is generally supposed. To form a good soil, its texture should be such as to retain a suitable quantity of moisture for the nourishment of vegetation, and be neither so clayey as to bake and crack in the heat of the sun, or heave by the action of frost; nor so sandy as to become parched, and be mere dust at the depth to which the roots of plants penetrate. Argillaceous soils have so strong an affinity for water, as to retain a small portion even when heated. There should be a sufficient quantity of clay in soils to enable them to retain three or four per cent of water when dry, and to convert the other materials into a loam. Perhaps a light loam, properly treated, produces the best crops.

---

* We do know of a more acceptable service that could be rendered to American husbandry, than the translation of these works, or a portion of them, into English. We have no doubt but the translator and publisher of them would be amply indemnified for labor and expense.

It is also necessary to consider the substratum, in judging of the productiveness of any particular soil.—If it be clay, or rock without fissures, the soil, however good in its texture and other qualities, will probably be "cold and wet." If the sub-soil be gravel or sand, the surface soil is frequently too dry, unless it be a loam so heavy as to retain a sufficient quantity of moisture for vegetation. Where a clay sub-soil occurs, it often alternates with beds of gravel and sand. Advantage may often be taken of this geological fact to drain wet soils, either by boring, or by sinking wells through the clay, into the gravel or sand below, so that the water will find an outlet in springs at a lower level, where these strata emerge on the sides of hills or ravines. In this way, stagnant ponds and marshes may be drained, not only so as to reclaim unproductive lands, but to render the surrounding country more healthful. These principles may be practically applied in many parts of Ohio.

However poor the texture of a soil, it can always be brought to a proper state of cultivation by art; but, unfortunately, the value of produce and the price of labor will not often justify the expense. Light and heavy soils may always be benefitted by a proper admixture of clay or sand, as the case may require. That clay and sand are almost always associated, is a geological fact of much practical value in agriculture, as well as in the arts. The occurrence of one, (unless from the effect of some local cause,) is a pretty sure indication that the other may be found in the vicinity. Light dry soils are often injured by removing the small loose stones, which, instead of being an injury, are in reality an advantage, as they not only prevent the evaporation of moisture below the surface, by shading the ground; but, by their slow decomposition, furnish stimulants and food for vegetation, thus acting as a permanent manure.

"2. *Chemical composition of soils.*

"The chemical as well as the mechanical composition of soils, exerts a powerful influence on vegetation.—Salts, alkalies, and alkaline earths, act as stimulants if used moderately; but if in excess, they are injurious. Many soils contain calcareous rocks, stones, or pebbles, which are continually undergoing disintegration and solution by atmospherical agents; and thus serve as permanent mineral manures. Other soils abound in stones derived from such rocks as contain potassa as a constituent, and by their decomposition, furnish this alkali, in solution, to the roots of plants, by which it is absorbed and carried into the circulation, and there acting as a stimulant, remains combined with some vegetable acid. The decomposition of gravel, pebbles and rock has been observed to be a benefit to vegetation; and as the rapidity of decomposition depends upon the surface exposed, it follows, that if such materials be ground fine and sowed upon the soil, like plaster of paris, a more decided benefit would be the result. This has been partially tried with success; and it is to be hoped, that the intelligent farmers of this state will give it a more thorough trial.

"Iron, in some states of combination, exercises a beneficial influence on vegetation; yellowish and reddish soils almost always contain iron, and are generally productive.

"MARLS.

"The value of marls for manure is well known.—The term marl, in its strict mineralogical sense, means an argillaceous carbonate of lime, but by general usage, marl is an earthy mineral substance, (or one which becomes earthy on exposure to the weather,) which, by being spread on the soil, renders it more fertile.

"The principal varieties of marl, common in this country, are clay marls, shell marls, and the gray and green sandy marls. Clay marl, and the fresh-water shell-marl are common in Ohio; and these deposits will become valuable at no distant time.

"A rock formation of great thickness, occupying a broad belt on the surface of the state, and undoubtedly underlying a large proportion of our territory, seems to be well adapted for use as a marl. It rapidly crumbles and disintegrates on exposure.

Fresh water shell marl is formed by molluscous animals, which secrete lime from the waters of the lakes and ponds, in which they live, to form their shells; and as generation succeeds generation, the dead shells accumulating, form thick and extensive beds of this material. When the pond or lake has shoaled to within a few feet of the usual water level, a growth of plants succeeds; and by an accumulation of vegetable matter, peat and "muck" are formed, and cover the marl.—The peat and "muck" near the marl are filled with small fresh water shells, similar to those which have crumbled down to form the proper marl. The pure marl is a white crumbly mass when dry, but unctous and plastic when wet, and contains a few small white fresh water shells. If vinegar or any acid be poured on it, it effervesces briskly.

"The value of fresh water shell marl is well known to some of our intelligent farmers; but few know it when they see it, and still fewer know in what situations to find it. For these reasons; I have particularized its character and its situations. It performs the same office on the land as air-slaked lime, and is as valuable, while it has not the causticity to injure vegetation. One object in burning lime, is to reduce it to the state of powder by slaking. The shell marl is already in a pulverulent state, and only requires to be dug from the swamps and ponds and spread on the land."

Beet Sugar.

It is announced in the New-England Farmer, on the authority of H. C. (Rev. H. Coleman,) that an important discovery has been made by a gentleman in the neighborhood of Boston, in the manufacture of sugar from beets;—by which *all* the sugar contained in these roots may be obtained; the raw material may be put in such a state of preservation as to be used in any season of the year; the process of manufacture is rendered simple and easily understood; requiring no expensive machinery, other than can be furnished by a farmer's kitchen; and the whole calculated to enable the farmer to produce his own sugar from his farm at a very small expense, compared with what this article now costs at the store. The proprietor is procuring a patent for his improvement. If these high expectations should be realized, the discovery will prove to be one of the highest importance to the country, particularly to the far west.

The following article, which we cut from a Northampton paper, has reference, probably, to the improvement above noticed, or to one very similar.

"The German improvement over the French method of making beet sugar, a patent affair in Europe, consists *simply in drying the beets*, which are then reduced to a powder by grinding, and changed into a decoction by adding water. The experiment has been thoroughly tried by Mr. Zachariah Wilder, of this town, which resulted in *complete success*. Mr. W. by this process, which, we understand, is as simple as that of making a cup of tea from aromatic herbs, has succeeded in extracting *ten per cent of sugar from the crude beet*—and he is confident that at least twelve per cent can be obtained at another experiment.—For his efforts in prosecuting his experiments to signal success, Mr. Wilder deserves the unqualified thanks of the agricultural world. The result of his labors will give an impetus to the culture of beets in Hampshire county, which cannot fail to be productive of lasting good. But to the process again. The dried powder of the beet was found to yield its saccharine immediately, as the decoction was found to be as sweet as boiled maple syrup, the moment the water was added to the powder. The means used for the clarification of the decoction were very simple. Animal charcoal and lime were the only agents employed. This eminently successful experiment proves the fact, that the immensely important article of sugar can be manufactured by any intelligent farmer's household, as easily as bread, pies or cakes can be made and baked. A rich garden spot of a quarter of an acre, can produce beets enough to make a thousand pounds of sugar; no heavy capital or incorporated company is required to carry on the business. Every individual can make a pound of sugar as cheaply and as easily as he can make a pound of Indian meal. This important fact has just been proved.—Now let us look at the amount of sugar brought into Northampton last year. Why, it amounted to *one hundred and seven thousand pounds*, which, together with the molasses consumed, would cost over $10,000. This is no inconsiderable sum to be expended by our citizens annually. A dozen resolute farmers, by their *influence* and labors combined, can create that sum from their lands this summer in the culture of the beet. At least, so we think."

Lime for wheat.—Dr. Jackson, geologist of the state of Maine, remarks—"I find by chemical examination of several remarkable soils, that a very minute quantity of carbonate of lime, viz. from one to two per cent, is amply sufficient to render them capable of bearing heavy crops of good wheat. I am also satisfied that a soil is incapable of producing wheat of good quality if it does not contain carbonate of lime; for this substance is an essential ingredient of this grain."

Importance of the Salts of Lime.

"I apprehend that the importance of the salts of lime in a soil is but little appreciated by farmers.—Their crops may fail, although they may have manured and tended them well; but it is almost always easy to find a cause that satisfies, in the character of the season; but hard to convince them that the failure may have been owing to the single grain in a hundred, of some substance that can be discovered when present only by chemical examination. And yet I doubt not many a crop has failed for want of that one per cent of sulphate or phosphate of lime.—Facts, indeed, seem to me to warrant the conclusion, that, without lime in some form, land will not produce any valuable vegetation."—*Prof. Hitchcock's report of a re-examination of the economical geology of Massachusetts.*

The salts of lime referred to, as having a salutary influence upon vegetation, are the carbonates, sulphates and phosphates, or lime chemically combined with carbonic acid, as in common limestone—with sulphuric acid, as in gypsum—and with phosphoric acid, as in animal bones. These all abound, more or less, in vegetables—the sulphate particularly in clover, &c., phosphate in barley, wheat, &c., and the carbonate in many plants. As they are essential, in minute proportions, in the organization of plants, they must necessarily exist in the soil, or be formed there by chemical process, or the plants requiring them will fail for want of these necessary constituents.

Dr. Perrine.—This worthy citizen, formerly our consul at Campeachy, has been indefatigable and persevering in endeavoring to add to the useful plants, and consequently to the productive wealth and independence of our country. He has been at great expense in transporting to Cape Florida many tropical plants, where the climate seems congenial to their growth, which promise to be of great advantage to the arts and to commerce, particularly some which afford an excellent material for cordage. The Doctor has petitioned congress for aid, by a grant of Florida land, and a report has been made favorable to his application. We sincerely hope the recommendation of the report will be granted. *Whatever benefits a part, benefits the whole of our country;* and that the Doctor's exertions, if suitably rewarded, will lead to the most beneficial results, we have not the least doubt. And besides, what he asks will not make the country poorer, but it may enable him to be eminently useful. We repeat, we hope congress will grant his request.

☞ *An admonition.*—Most of our old farms have been worn out, or greatly impoverished, by bad management; and many of them are in the process of expensive renovation. As prevention is cheaper than cure, those who are upon new farms should be admonished, not to "kill the goose which lays the golden eggs." Constant cropping will ultimately impoverish the richest soil; as will the practice of carrying *all* off, and returning *nothing*, in the shape of manure, to the soil.

☞ *Fine Animals.*—We are happy to state, that there is now in the hands of Mr. Hall, the artist, accurate likenesses of some choice animals, belonging to an eminent American breeder, which, with a letter press description, we hope soon to exhibit to the readers of the Cultivator.

A Nursery for sale, containing a great variety of choice fruit trees, and many thousand seedlings, situate on the Kentucky side of the Ohio, opposite Cincinnati, with a farm and suitable buildings, if required. A professional nurseryman may obtain an advantageous bargain, by communicating with S. C. Parkhurst, Cincinnati, Ohio.

☞ *See Last Page.*

CORRESPONDENCE.

What is a Load of Manure?

DEAR SIR—I often see in the Cultivator, particular accounts of large crops, in which I am much interested. In these accounts, the *number of loads* of manure applied to the acre is generally stated, but I am always at a loss to know how to calculate with regard to the *quantity* of manure thus used. Some farmers call a common cart body full a load; others do not call a cart well loaded unless they have on a pair of wide sideboards full; so that the statement of a certain number of loads to the acre, without being more explicit, is only calculated to leave the reader in the dark.

I have been for some years past in the habit of drawing annually a large quantity of manure from Hartford, (six miles.) It is all measured, and we call ninety-six solid feet a load; but one of these loads will more than fill two common cart bodies. If your correspondents would always state the quantity of manure used, in cords or solid feet, all could judge more correctly with regard to the good or bad management of the person making the statement.

I find my crops generally increase in proportion to the quantity of manure used on an acre.

Yours very respectfully,
D. N. GRANT.

Bloomfield, Conn. April 11, 1838.

REMARK.—The general meaning of a *load of manure*, we believe, is what can be conveniently drawn by two horses or two oxen, to the field where it is to be used. At Boston, and it seems at Hartford, we apprehend, it implies *as much as can be drawn by four or six cattle upon a hard road*—or "ninety-six solid feet."

Culture of Clover and Melons at the South.

Scull Shoals, Ga. 20th April, 1838.

Judge BUEL—I have read the numbers forwarded me with much satisfaction and improvement, and feel no hesitation in believing that they will prove highly useful to all who will read and understand them; they contain much information useful to the south, particularly the cultivation of corn and the saving of manure.

For the last three years, I have been making some experiments with red clover, timothy and orchard grass, and find that if sown about the last week in September or first in October, that we can have as good a stand of clover and grass here as you have near Albany.—From a small lot of four acres, I last June cut as fine hay of clover and timothy as I ever saw grow at the north, it being from three to four feet high. I put about four hundred bushels of cotton seed on this land, which I have no doubt is a better manure than gypsum. On my alluvial bottoms, it thrives exceedingly well without manure, but on our exhausted fields, a good coat of manure is indispensable. When sowed in the spring it comes up well, and then dies from the heat and dryness of our climate.

I take the liberty of sending you twenty-four water melon seeds—the twelve white looking seed is called the mountain sprout, and has a rich yellow meat—and the twelve dark seed I took from a melon that weighed thirty-eight pounds, and three-fourths of a yard in length—the latter has a blood red meat. They are, without doubt, two of the most delicious varieties that can be found any where. I cultivate them thus:—I have holes dug in the ground, ten feet distant each way, eighteen inches wide at top, and twelve deep. I then have the holes filled three inches above the surface of the earth, with rich light earth, and plant and cover the seed about one and a half inches deep, leaving two stocks in a hill. The ground between the hills I keep well ploughed or harrowed until the vines begin to run. They must then be hoed often, to keep the earth light. A southern exposure on a hill side is the best, and the poorer the ground the better, except where the hill is made. I am of the opinion that any climate that will mature Indian corn, will mature the water melon.

Most respectfully,
T. N. POULLAIN.

Improvement progressing in the South.

Georgetown, D. C. April 25, 1838.

J. Buel, Esq.—Dear Sir—We have had several very cold days—ice one-quarter of an inch. Great fears were felt for the safety of the early fruit, as it was in full bloom; but I am happy to say from the best information, that it has escaped with very little or no injury. Our winter crops, wheat and rye, look well, and promise a better harvest than we have had for many years.

The spirit of improvement among our farmers is increasing daily. To give you some idea—there has been two or three times as much clover seed sown this season as last, and would have been more if it could have been had. Yours very respectfully,

JOHN H. KING.

Miller's Tolls.

Burlington co. N. J. 4th mo. 14th, 1838.

Friend Buel—I see in No. 1, of the present volume of the Cultivator, some complaints of the extortionate toll of the millers in your state, and am surprised to see them make no vindication of their cause in the last No. and admit it looks somewhat unfavorable to them; but such being the case, I feel disposed to defend them in some measure, at least, as I fully believe they are not as censurable as you deem them to be; as you appear to make no other deduction than the customary and with us lawful tenth, allowing nothing for filth, fixed air, nor any thing else; the former of which, with *some* customers is considerable, and in such cases, according to your standard, the miller's expense for cleaning apparatus and gratuitous labor, would only add to his condemnation; and further I apprehend you are not aware, (for if you are, you should have mentioned it,) that in solid bodies, there is fixed air, that in being reduced or pulverized escapes, and thereby a loss of weight is sustained, of which fact nine-tenths perhaps of the agricultural community are ignorant, and if so, no wonder that millers should be accused of taking too much toll. I have found by careful experiment in grinding rye, (weighing 56 lbs. per bushel,) with my own hands, long before I saw the account in the Cultivator, that it lost three and a half pounds per bushel, or twenty-one pounds in six bushels, the quantity ground, and which added to the toll, would amount to about 16 per cent.

Oliver Evans, late of Philadelphia, in his Millwright's and Miller's Guide, note pp. 159, 160, says—"If we consider that most bodies are in part composed of air, which is in a solid or fixed state, and constitutes a proportional part of their weight, and this proportion is different in different species of matter, from one-sixteenth to one-half, and in one species of wheat has been found by experiments to be one-fifth of its whole weight, that is, 12 lbs. of fixed air in 60 lbs. or one bushel of wheat." (Alas, for the miller's reputation who might grind such wheat, it being weighed before and after taking it to mill.) "Now this air is roused into action two ways, viz. by fermentation and by heat, and as fast as it is roused, it instantly leaves the body and expands itself into about a million times more space than it filled before in the form of a dense body. *See Martin's Philosophy*. As a confirmation of this hypothesis, we may observe, that many experiments have been made by weighing a quantity of wheat carefully before it was ground, and then weighing every thing it made in manufacturing, and we have found it to be lacking in weight from one to five pounds per bushel, which could not be accounted for any way better than supposing the loss to be occasioned by the escape of fixed air." This air being roused into action by heat, grinding grain when stones are dull, or glazed by garlic or the grain damp, occasioning more heat, it will consequently produce a greater escape of the air, and greater loss of weight will follow. Now thus circumstanced, can any miller possibly escape censure, though acting ever so honestly? Certainly not, and I have no doubt that owing to the ignorance of these things, and the negligence of properly cleaning their grain by some customers, many honest persons have had their reputation blasted and their incomes much curtailed, and that too upon the strongest possibly conceived evidence on the part of their accusers, viz. "weighing before and after grinding," deducting the toll only.

I do not make these statements as a shield for dishonesty in the least, for no doubt there are many who follow the occupation of milling, whom it would be well to keep a strict watch to; but for the information of the public, and to exonerate the upright from unmerited disgrace.

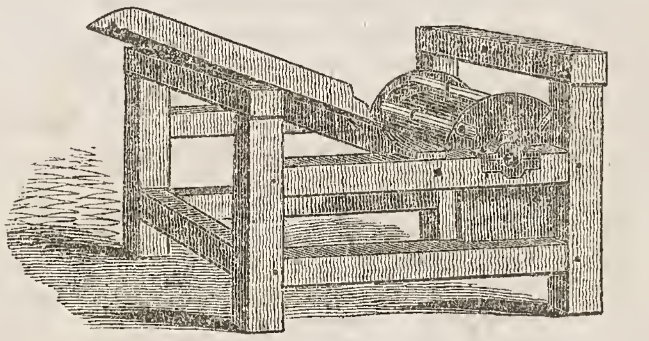
I would recommend thee to make proof of these matters by some honest miller, if there is any to be found in thy neighborhood, under thy own close inspection and observation, the motive unknown to him, and publish the result in your highly useful and interesting paper. Respectfully thy friend,

DAVID WALTON.

Remark.—There is no doubt much truth in the remarks of our correspondent, as to the diminution in the weight of grain by grinding. But it is not so much the amount of toll which is objected to, as the want of a *legal* or other *standard* of toll, so that a customer may know when he is dishonestly dealt by; and we do not know of a better way of coming at this fact, than by "weighing before and after grinding."

Webster's Spring Beater Threshing Machine.

[Fig. No. 35.]



The above cut represents one of D. H. Webster's machines, with the top off. It has been in use for several years—is very simple in its construction, durable, and not liable to derangement. The heads of the drum or cylinder are of cast iron, and sixteen inches in diameter, the cylinder twelve inches, and sixteen inches in length. There are four wrought iron fluted beaters extending from one head to the other, supported in the centre, the ends turned to fit in a groove in the heads which admits of half an inch play, and kept to their place by means of springs. The advantage of this play is, that in feeding, sometimes a larger quantity of grain is drawn in, and the elasticity of the springs lets it pass through. The bed plate is cast iron, with ribs running across.—The frame occupies four feet in length and two and a half in breadth.

The advantages of this machine are, safety, durability, and simplicity. Stones, pieces of roots, sticks and even a hammer has been thrown into the hopper, without injury to the machine or those attending, which in a spike machine would not only endanger those attending, but would injure and most probably destroy the machine.

With one of Allen's powers it is capable of doing as much execution, threshing as clean, and breaking the straw less than the spike machine.

This thresher was exhibited at the fair of the American Institute, in October last, for which the committee awarded him a silver medal, for the best threshing machine exhibited.

They are for sale at the store of Messrs. Geo. Russell & Brothers, corner of State-street and Middle-lane, Albany. Price $35. B.

Albany, June, 1838.

Agricultural Employment Commended.

"Agriculture is the most healthy, the most useful and the most noble employment of man."—*Washington.*

Mr. Editor—I have made a short extract from the writings of Washington, on which to base a few plain and honest remarks. Being a man considerably advanced in life, and one of the laity, and not possessing a very good education, the reader must not expect a great display of erudition or of scholastic accuracy.—My object is to make some common-place suggestions for the encouragement and consolation of the farmer. From my youth up, I have been principally engaged in *agriculture*. Yet I have endeavored to get some knowledge of *other* occupations, so as to be able to compare and judge which is the most *healthy*, the most *useful*, and the most *noble*. And with the greatest sincerity, I can echo the sentiment of the intelligent and worthy Washington. I very well know, that this is not the opinion of many, *very many* of the community; yet it is *unquestionably* well founded. Ask the *dandies*, who are perambulating our streets, dressed in all possible finery, living upon the hard earnings of their parents, and they will tell you they consider agriculture a *dirty, degrading* business. Ask those

"Who lounge about in lazy bands,
Throng tippler's shops and tavern stands,"

and *they*, too, will tell you that farming is not the business for them. But, ask the truly intelligent and meritorious, and they will tell you that agriculture is the *main spring* of all employments. That not only the *peasant* but the *king* is served by the field. That it is not only *useful*, but highly *honorable*. They are ever ready to reiterate the sentiment contained in the following lines:

"Good Cincinnatus, at his plough,
With more true glory shone,
Than Cæsar with his laurel'd brow,
His palace and his throne."

The extract on which I have proposed to remark, contains three propositions:—The first is, of all employments, *agriculture is the most healthy*. This is evidently a fact, from the following considerations:

Man was created for *exercise*. Toil must nurture him, or else his powers and faculties will never ripen. When this cannot be brought about, he sickens and dies. Taking into consideration the regularity that may attend a farmer's labors, the regularity in meals and sleep, and the salubrity of the air he breathes, and the sun that warms and vivifies him, we at once perceive, that no employment is so well calculated to aid the functions in fulfilling their purposes. As vegetable creation is affected, so is animal. Shut out the sun and air from a vegetable, and deprive it of terraqueous, or natural aliment, and how soon it will become sickly! just so with the human family.

Again—agriculture is well calculated to afford peace of mind. A farmer's business being very much within himself, there is not that chance for altercation, disappointment, perplexity and mortification, that other men experience. Just compare with the professions. The *clergyman*, if he make every effort to give satisfaction to his parishioners, must meet with disappointment.—If he preach like one inspired, he cannot please them all.

"Some wanting grace,
Laugh in his face,
While solemnly he's prosing;
Some sneeze or cough,
Some shuffle off,
And some are even dozing."

"The *lawyer* leads a harrass'd life,
Much like a hunted otter,
And 'tween his own and other's strife,
He's always in hot water."

I should like to say something better of a *doctor's* business, but am not able.

"For like a tavern waiting man,
To every call, he's 'coming,'
Now here, now there,
Must he repair,
Or starve, sir, by denying;
Like death himself,
Unhappy elf,
He lives by other's dying."

The next proposition is, that *agriculture is the most useful*. And how can this be, when so many other employments are so useful? I will give an explanation, my dear readers, for it is very capable of illustration. The community, or the different classes of people may, very properly, be compared to the human frame, which is composed of body and limbs. All the members are very useful in their places. One cannot say to the other, I have no need of thee. Yet, we may at once perceive, that they are not equally important. A *leg* or an *arm* may be amputated, and yet the person or the body may survive; though it must be a great loss. But kill the *body*, and the limbs will die also. So with the community. The farmers are the *body*, the other classes are the *limbs*. Now amputate or cut off these limbs from society, the body may survive, though it must of course suffer much. But destroy the body, or farming interest, and all is lost.

The third and last proposition is, that *agriculture is the most noble*. This is acknowledged by all noble minds. It is what heaven ordained that man should pursue. It is the business in which our first parents were engaged. It is the business that has and must sustain the human family. It is noble in itself—it produces noble effects. How it ought to ennoble the mind, to be employed so much among the works of nature. How it ought to lead the mind from nature up to nature's God.

"A farmer's life 's the life for me,
I own I love it dearly;
And ev'ry season full of glee,
I take its labor cheerly."

AN AGRICULTURIST.

Westborough, Worcester co. Mass. May, 1838.

On wintering Sheep.

In *rural economy*, as well as in the *arts*, our success is generally expected to follow *industry* and attention to our husbandry; but unless we use both *care* and *skill*, our labor will be of but little use. The wise proverb, that "the hand of the diligent maketh rich," will be of little avail, unless we give proper attention to *little things*. *Hard work* will not advance us in prosperity unless we *work it right*. We always find some farmers' stock in good condition—and why? Because they work it right. In an adjoining fold, their neighbors remain in poor condition, notwithstanding they may be sufficiently supplied with fodder of the best quality. This farmer heeds not *little things*. He does not take up the "stich in time" to ensure success.

The season will soon arrive, when sheep require more attention than farmers in general are apt to bestow on them. To do well through the winter, they must be in good condition when they begin it. Sheep *well summered*, and got up to hay in good heart, are *half wintered*. It is with us, a very common practice to permit them to ramble over the fields late in fall, until snow obliges the farmer to bring them into his enclosures. They may look full on the frost-bitten herbage, but it does them little good; there is but little nutriment in it.—They should be confined in dry enclosures, between the 10th and 20th of November, while in good heart, and fed on the best of early mown hay. In wintering lambs, the foundation of so much loss is more frequently laid in the fall, by leaving them to cut their own fodder until winter sets in, than by all other neglects.

The different kinds of wethers, ewes and lambs, should be separated; and each flock of a size, that they not materially get the advantage one over another. It is also necessary to keep the old and poor sheep separate. As soon as one begins to decline, it ought to be removed into the hospital, where it can receive better attention; and it is highly beneficial that dry airy sheds are prepared, that they may not be exposed to the rigors of the winter, and cold storms in the spring.

Smut or ergot was very abundant the two last seasons, on the heads of June or spear grass. When this abounds, hay must be thrown out more abundant, that they may have a selection of food. I have known large flocks nearly all destroyed by this vegetable poison. They should be winter fed to the degree of commencing the grass season in good store order, without having sustained any check in carcass or wool. It is of the utmost importance to keep them on as dry grounds as possible in the spring. Wet feet will relax the system, it introduces a general debility, and loss of appetite. One of the principle causes of the internal rot in sheep is by their wading in wet yards, and feeding on wet grounds.

We often hear the idea presented, that the *breed is nothing* and *feed is every thing;* that this is in fact all that is necessary to make fine animals; but this notion is one that ought to be exploded. Good keeping is an excellent thing, and is not doubted; the farmer that keeps his flocks well is paid down; a fat sheep requires less hay by one-fourth than a lean one; they also produce more weighty fleeces, and more lambs; but it was never known to produce any material change in animal physiology.

The yolk, or oil, which by perspiration is secreted in the wool in warm weather, returns again into the system in a cool day; this gives a fat sheep the advantage to withstand the sudden changes of the weather, better than a poor one; and this yolk adds weight to the fleece, when shorn in a hot day; by the same rule wash them in moderate weather to preserve the oil. I have often seen flocks of sheep decline in spite of all the care and feed that could be given; but in this case, it is not wholly depending on good attention and a plenty of nutritious food for a remedy; any species of animal nature will decline in a few generations, when propagated by the same family blood.

Exercise is one very essential point, which may be produced by feeding them within ten or fifteen rods of a warm fount of water, that should not stand in a bleak windy field; and if they can have another barn or stack to run to once a day, it will give them exercise, a change of food and an appetite. To satiate their thirst on snow for a length of time is a wrong notion, and ought to be exploded. Unless they are fed on roots, they will not do as well without water, which should be convenient to them at all times.

It is very healthy for sheep to run among burned logs and stumps after being shorn, through the summer; the coal dust drives into the wool, and is a sure and simple remedy for ticks. I have tried no other method in summer to prevent these vermin, and have always been successful in preventing or expelling them.

Pine or hemlock tops should be put in their way, when they have been kept from the ground for any length of time, to invigorate their health. Where the hay is not salted, it is of importance also to brine it in mild weather now and then.

I always cut my mows, and first feed out one-half.

> "I then can judge on candlemas day,
> Whether I have more stock than hay."

It is also an economical way of saving fodder. Fresh hay is as much better for stock, as a slice of bread is for man, just cut from a loaf.

The agriculturists generally throughout our state, are applying their serious attention to the growing of wool, with the *hopes* of a fair remuneration for their enterprise. The price of the last clip did not range so high as was expected; still we are inclined to believe, that wool will do a shade better the present season; an unusually small stock of old wool remains on hand; it has not been so generally sold off and manufactured for a number of years, in this state. Our increase in sheep for the last five years has been very rapid. The present number may be estimated at two millions. In one township, rising seventy thousand have been assessed, and probably a greater number were owned. The average annual expense of keeping sheep in Vermont will not much exceed one dollar the head.

Dear sir—I respectfully submit the above for your consideration. And believe me, with great respect and esteem, to be, very truly, your obedient servant.

SOLOMON W. JEWETT.

Weybridge, Vt. May, 1838.

Italian Spring Wheat in Ohio.

Waterville, Lucas co. Ohio, April 16, 1838.

J. Buel, Esq.—Sir—I have thought for some time, that I would send you the result of my experience in the culture of Italian Spring Wheat, in the valley of the Maumee, believing as I do, that the dissemination of information upon the agriculture of this region, will be acceptable to a large class of the readers of your paper. I sowed last spring, six bushels of wheat procured of J. Hathaway, of Rome, N. Y. a part upon the bottom lands of the river, and the remainder upon what is called the "second bottom," which is a light sandy soil of moderate richness. No more than ordinary care was taken with the crop, even for this country, where the business of agriculture is carried on rather loosely at the best. Some of it suffered considerably from weeds, and I was far from considering this experiment a fair trial. I harvested one hundred and twenty bushels, the product of the six bushels of seed, of plump, fair, heavy grain, in all respects as good as the seed, while from twenty-five bushels sowing of winter wheat, every way as well put in and taken care of as the other, I only harvested one hundred and sixteen bushels, so great is the loss from winter killing in this part of the state. As an evidence that I consider the spring wheat one of the most valuable acquisitions to the agriculture of this country, I have already sowed eighty bushels of my crop upon my best lands, and shall continue sowing till I have exhausted my stock. Some of the wheat is already up, and looks finely.

With respect, I am yours, &c.

HENRY REED.

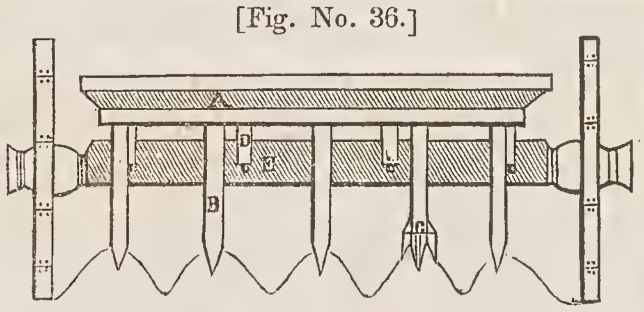
Scotch Turnip Drill.

J. Buel—Dear Sir—When in Scotland for a time, some years since, I remarked a good method they had of cultivating ruta baga. You may have published it; if so, I have not seen it. (It is but lately I have read that excellent periodical of yours.)

It is this. Having first ploughed the land in ridges, about three feet apart; then, with a drilling machine, the drills of which are graduated to the width of the ridges, and whose wheels run in the centre of the furrows, having four or five ridges between them; the drills of the machine entering the top of each ridge, and depositing the seed there, which is covered over by two irons inclined to each other at the hinder ends, and attached to the machine.

The chief good resulting from the plan, is in the thinning out and hoeing the crop; the former is done by one stroke of the hoe between the plant to be reserved and that part of the row which is untouched, pushing the refuse plants, &c. into the furrows, leaving the proper plants, with a small portion of their roots in the ground, and blowing about in the wind, which causes them to grow the faster; (so the farmers there assert.) When the weeds are grown, and the ground requires hoeing, the ridges although flattened down in the thinning of the crop, are again submitted to the same operation of pushing and pulling the earth and weeds into the furrows on each side, where if they vegetate again, they are removed by the horse hoe, till totally eradicated. The crops grown by this method are very great, although I have no means of informing you of the number of bushels, at this space of time. Suffice it to say, that part of Scotland, (East Lothian,) is reputed to be as well farmed as any part of the kingdom.

[Fig. No. 36.]



PLAN OF DRILL.

A. Box for holding seed. B. The drills, pointed with iron, and hollow for conveying the seed to the ground. C. Irons for covering the seed. D. Pieces connecting the drill, &c. to axle tree. E. Hinge attaching the axle to the pieces, &c.

If the above is new and worthy a place in your paper, you are welcome to it. It may be interesting to some of your eastern readers, whose lands are not crowded with stumps. Yours, J. E.

Lockport, N. Y. April 24th, 1838.

Indian Corn.

April 25th, 1838.

Jesse Buel, Esq.—Dear Sir—As every thing relative to Indian corn and its culture is particularly interesting to your subscribers throughout that great extent of our country where this grain constitutes the chief staple, I hope you will permit one who has been a corn maker for nearly half a century, to offer a few remarks upon several articles on the subject in your number for this month.

And first, of Dr. Brown and his varieties, in regard to which, as well as to his criteria for selecting seed-corn, I differ from him essentially. He has fixed upon the number of rows of grain on a cob as constituting a variety; yet *nature* has caused the same stalk of corn very often to produce ears having cob and grain exactly alike in color and shape, but differing in the number of rows upon each, from two to six or eight. Difference therefore in the number of rows, should not be considered as constituting a variety. Again, he names as a variety, but one kind of gourd seed, which he calls "genuine,"—that is the yellow—yet *nature* has made another which is white, and much more common to the south—having, not unfrequently, from twenty-four to thirty-four rows on a cob. The grain, however, has the same shape with the yellow gourd seed, and is evidently so called from its resemblance in shape to the seed of the common gourd. Of the doctor's classes, I can only say, that the rules by which he has formed them, and the characteristics which he describes as peculiar to each, appear to me both too vague and inapplicable to be useful. Some of his names, for example, are known only in a very small extent of country, and cannot of course, be intelligible at a distance; while he gives to some of his varieties the names of particular states; although in regard, at least to Virginia, I can certainly say, that it would puzzle a jury of the most experienced planters among us, to tell which variety of corn, out of fifteen or twenty, had the best right, if either had, to the name of our state. His third principal class I perceive, he has christened "Hæmatite, or blood-red."—Now if he means the second term as a translation or explanation of the first, it hardly applies to any one of the ten sub-classes which he has ranged under this chief one. In fact, it is inapplicable to any kind yet known; for hæmatite is a hard mineral substance, either *red, black or purple*, but the powder of which is *always red;* whereas, the powder of all the varieties of corn I have ever heard of is always white, or yellowish. The variety which the doctor calls "Guinea corn," if it be the same so called in Virginia, is not a corn at all, but a species of millet. His No. 32 is said to be quite as common in South-America as in Texas, where a small yellow grain corn is more generally cultivated than any other, at least in the country round about Galveston Bay. The proper name of his No. 32, is "tunicata" corn, from the circumstance of each grain having a distinct cover or coat.

Permit me now to examine his criteria for choosing seed corn. That which he ranks first is, "*the most stalk*," and if he goes upon the principle of "first named, most honored," we have a right to conclude that the doctor considers the quantum of stalk the most valuable of all the qualities of the corn-plant. My experience tells me that it is the least valuable; for it by no means follows that the variety which has most stalk, will produce either most fodder or most grain. The first depends more on the number of joints in a stalk than on its height; for the number of joints differ materially in the different varieties, and each joint bears a blade; while the quantity of grain depends more on the number of ears, than on their relative size, and the number is almost invariable smaller on very tall stalks than on those of a medium height. In verification of this, there is no remark which is more commonly heard among us southern corn-makers, than "that corn," (speaking of some particular crop,) "is running quite too much into stalk, and shooting too high." Again—as to the value of corn stalks: no animal to which we southerners have ever offered them when dry, naked and stripped of all their blades and imperfect shoots, will eat them, unless we cook them somewhat after the recipe for making good soup with common pebbles—that is, to put in such ingredients as will make good soup of themselves, and call it "stone soup." In fact, corn stalks of themselves, are fit for little else than to act as absorbents of manure, when thrown into farm-yards, and would not be worth the labor of collecting, but for this circumstance.

The doctor's second criterion is, "*the largest cob;*" a recommendation to those who love corn cob pipes; but for nothing else. For although it is certainly true, that the largest cob will generally contain most rows of grain, yet there are several exceptions; for some varieties have very large cobs and grains comparatively broader, in all which cases the rows will be fewer in number than on cobs of equal size with narrow grains. Again—the greatest number of rows will not always produce the greatest quantity of grain by measure, unless the grain be considerably larger than the kind with which it is compared; for all which reasons I deem the doctor's second criterion no better than his first.

Let us next examine his third, which is, "*the longest grain.*" Now it is notorious to every southern corn-maker, that all the longest grain varieties are what we call "*chaffy*," and are far less weighty, measure for measure, than the short grain varieties. This we consider a decisive proof that they have less of "*the farinaceous product*," although I have not heard of any accurate experiments having been yet made to ascertain the fact.

The fourth and last criterion named in this fanciful classification is, "*early growth and quick culture.*" This last term, (if I understand it,) is merely an incident that may or may *not* happen to all cultivated plants whatever, but is not a quality in any. "*Early growth*," or I should rather say, *early maturity*, is certainly a recommendation; but far more important to the north and east, than in what may properly be called the corn region of the United States. Within *its* limits it is universally true, that the varieties which ripen very early—say three or four weeks before the kinds most generally cultivated—although heavier are much less productive: so that his fourth criterion would be still less suitable in the southern country, than either of his others. In short, if we southern corn-makers were to go by the doctor's rules, in choosing our seed corn—rules indeed which are so incompatible with each other that they never could be true of any one of his thirty-five varieties—we should soon have to apply to some other corn doctor for farther advice.

The next remarks which I beg leave to notice relative to Indian corn, appear to be editorial. They are contained in an enumeration of the advantages of "*cutting* *up corn,*" over the practice of "*topping it.*" I cannot speak from experience in regard to the whole of them, but am confident that the writer is mistaken at least in *one* of his assertions, if he applies it to southern as well as to northern and eastern corn. He says, "*two smart men cannot top more than one acre a day.*"— Where corn is planted as thick as it always is to the north, this may be, and I presume is true, as the writer states it for a fact; but in a vast extent of our southern country, wherein our corn is left to stand much thinner and more distant, two acres topping would be deemed but a poor day's work, even for *one* "smart man;" for the process with us is a very different sort of business from what it is "down east,"—our laborers having acquired, by long practice, a degree of dexterity in it incomparably greater than an eastern man who had never witnessed it, could believe possible. Again—the writer affirms, that "a hill of corn is gathered at a single blow," in cutting up; but no implement ever yet used among us will do this on our corn, where three or four stalks are left in a hill, which is sometimes the case. Indeed, it requires a strong man, with a sharp hoe always to cut up even two stalks at a single blow, after they have attained their full size.

Under the head of "*succoring corn,*" there is a remark which requires explanation. It is in the following words: "The opinion has been given, and we think well sustained—that the succors perform an important office—that the pollen of the tassels impregnates the male* blossoms after that of the main stock, which develops earlier, has been blown or fallen off."† Now I have always before been taught to believe, that the *male* of every species of animal or vegetable whatever, was the impregna*tor*, and never the impregna*ted*. If, therefore, the male of the corn-plant is an exception, I should be highly gratified to see the proofs. Again—I am at a loss to understand to what part of the main stock the term "blossoms," is applied, for both the tassel and the silk of the ears are generally dry on southern corn, in our climate, before any pollen at all appears upon the succors, supposing them to be left.

The practice of tarring seed-corn, which Mr. L. J. Hopkins has so highly commended, is very generally followed in Virginia, and I believe in the Carolinas.—He could get thousands of planters with us to concur with him in opinion, that it is preferable to all others in preparing the seed. But care must be taken not to use too much tar, or it will injure and retard the coming up of the grain. A single pint to ten or twelve gallons of tepid water is quite sufficient. This should be well stirred before the grain is put in, after which the mixture will be found adhesive enough to attach to each grain as much gypsum or lime, (for both are used,) as may be deemed necessary.

I have been induced, sir, to offer these remarks from a thorough conviction that no subject is more interesting to a very large portion of our agricultural brethren, than that of Indian corn; and moreover that the knowledge they possess of it, still falls very far short of what it might be, if such a course of judicious experiments were instituted and persevered in, by the best informed among them, as might easily be made, and at a very moderate expense.

Should you deem the foregoing observations worth a place in your highly interesting and valuable journal, I present them to you for that purpose, and remain,

Your friend and constant reader,
CORN-PLANTER.

NOTES OF THE CONDUCTOR.

* An inadvertent error of ours. For "*male* blossoms," read "*female* blossoms," or silk. New silk frequently puts forth, in the north, after the first silk has become partially dry.

† We are inclined to favor, though we are not confirmed in this opinion. The pollen, the "impregna*tor*," on the main stock, is sometimes blown off, or beaten off by rains, before all the silk, the "impregna*ted*," has protruded from the husk. Hence a portion of the latter does not become impregnated by the pollen from the main stock, and the terminal end of the cob is consently barren. The tassels of the succors, being later in putting forth, and less exposed to winds, assist to complete the process of impregnation. As an evidence of this, we call to mind the fact, that the earliest ears are always best covered with grain, while those which push late often exhibit a quarter, a third, or a half of naked cob, in consequence, we presume, of want of impregnation. This explanation, we trust, will clear up the obscurity in the text, which seems to have puzzled our correspondent.

Agricultural School.

Albany, 16*th April*, 1838.

To Hon. J. Buel—Sir,—It is with no small degree of difficulty that I comply with the request you were pleased to make in a recent conversation I had with you, in relation to a judicious plan of instruction for the "New-York Agricultural School," and the advantages that will be likely to result therefrom; for my experience has not been extensive nor varied enough for so important a purpose. Therefore, I can only submit the following abstract, which, if it should merit your approval, and be deemed worthy of an insertion in the Cultivator, you are at liberty to make that use of it; if you think otherwise, you have my concurrence.

The chief object of the school should be to form practical mechanics, civil engineers, operative chemists, veterinary surgeons and practical agriculturists. It should be endowed with six professorships of the following subjects:

1. Mathematics and Design.
2. Rural Architecture and Civil Engineering.
3. Natural Philosophy and Practical Mechanics.
4. Geology, Mineralogy and Chemistry.
5. Entomology, Botany and Practical Husbandry.
6. Comparative Anatomy and the Veterinary Art.

The preparatory studies for entering the school should be reading, writing, English grammar, common arithmetic, history, geography, and book-keeping by single entry. No pupil should enter who is under seventeen years of age, who does not sustain a good moral character, and who has not a constitution adapted to active employment in the field.

The instruction of the school should be of two kinds, *general* and *special.*

The *general* instruction should continue two years, to be comprised of *courses* given by the professors at suitable periods, commencing each year on the first Wednesday in January, and continuing until the first Wednesday in September, from which, to the first Wednesday in December the pupils should be put under general examination upon all the branches in which they have received instruction.

During the entire courses, the pupils should be interrogated by the professors on the various branches they are pursuing, and should perform manipulations in chemistry, natural philosophy, mechanics, engineering, rural architecture, and ornamental gardening; and whenever the season would permit, to devote a portion of their time to tillage and other kinds of work connected with rural affairs, and occasionally to accompany the professors or their adjuncts on botanical and geological excursions.

The drawings should consist of plans made with the scale and dividers, and of outlines sketched by the hand relative to the courses pursued; the whole of which should be executed by the pupils, and should be duly verified by the professors. What has been said of the drawings should be repeated in regard to the manipulations. They should be sufficiently numerous to give to the pupils a positive knowledge of every branch pursued.

Independently of the interrogatories and manipulations, as stated above, the pupils should have general meetings for discussing topics relative to their studies, and for digesting memoirs upon various questions of political economy, statistics, &c.

At the end of the second scholastic year, the pupils should submit themselves for examination for their fitness or unfitness of entering the duties of their special education; and if they receive their certificate of capability, they should name, with the consent of their parents or guardians, the career for which they design themselves, and during the third year they should be practically employed in the kinds of business they intend to carry on. Should they be deemed incompetent to enter their special education, they should be permitted to repeat their course of studies, or to depart without any certificate of capability, or even of their connexion with the school.

At the general examination at the end of each scholastic year, there should be selected from the school six of the most distinguished pupils, who should serve as adjunct professors, and who should receive, besides this distinction, their instruction gratuitously during the third year. Independently of their special duties, they should assist their professors, and give elementary lessons to pupils whose preparatory studies may have been too small.

The *special* instruction should occupy the third scholastic year, during which the pupils should be actively engaged in the kinds of business for which they design to prepare themselves, whether to pursue general studies so as to qualify themselves for professors, or to become practical mechanics and civil engineers, operative chemists, manufacturers, veterinary surgeons, or practical agriculturists. They should then be placed under the special direction of the professors of the branches they pursue, who should afford them daily conferences, to point out to them a plan of operations, to follow their progress, and to designate the portions of the courses it would be useful to repeat anew.

The school should be furnished with a library of select books on mathematics, natural history, agriculture and the veterinary art. It should be provided with an extensive philosophical and chemical apparatus, and with a collection of plants, minerals and anatomical preparations. There should be constantly kept on the farm a large stock of the most useful breeds of domestic animals, and an hospital for the reception of sick animals and for veterinary practice. The farm should be large enough to produce a sufficient quantity of food and vegetables for the animals kept upon it, and to embrace as great a variety of soils as possible, and a water privilege. It should be principally tilled by the students, who should be practically instructed in the nature and composition of soils, the economy and preparation of manures, the adaptation of crops to particular soils, and the alternation of crops.

The buildings belonging to the establishment should be well constructed, and adapted to the objects for which they are intended. The laboratories and work-shops designed for manipulation and experiments should be spacious, so that a large number of students can labor in them at a time. There should be attached to the school a carpenter and wood-turner's shop, and of a mounter and turner of metals. Workmen should be employed under the eyes of the students, whether in constructing models for the collection of the school, or in making parts of machinery ordered by the pupils in their exercises, and to give them proper notions upon the handling of tools, the use of the forge, &c.

In fine, there should be placed in the hands of the students all the materials necessary for the construction of agricultural implements and machines, and such as are employed in rural architecture; and, in order to give the work as practical a character as possible, they should have at their disposal a certain number of models, implements, and machines which they can put up and take down, to operate, and to submit to such trials as will enable them to estimate their useful effect.

There should be connected with the school, either directly or indirectly, into which the students could be introduced in order to study the operation, establishments for the fabrication of chemical products; for the making of charcoal from wood; for the preparation of coke; for the extraction of marine salt; for the preparation of lime, gypsum, potash and soda; for the making and refining of sugar; for the preparation of wine, beer, cider, oils, tallow; and for the manufacture of flour, starch, soap, candles, and numerous other products; which would afford the students means to acquire a practical knowledge of the labors relative to their fabrication.

Such is a general plan of what may be deemed proper to improve the condition of our agriculture. Independently of the special objects of this seminary, young men will find a positive education, which will inspire them with a taste for agricultural pursuits, because they will see that labor guided by science is fruitful in useful results. Such a course of instruction will offer to those who shall distinguish themselves a station in society as honorable as it is lucrative, and will be regarded equivalent to a collegiate education, in harmony with the spirit of our institutions, the importance of which will be more and more felt, in proportion to the growth of the mighty west, which will receive new developments, when its political influence is better understood.

When we reflect upon the great interests of our country, we cannot but look with regret upon the neglected condition of our agriculture. For some years past, this all-important branch of industry has experienced serious obstacles, not only from being viewed by many as a degraded occupation, but from the want of attention and intelligence in the great body of our population. We have in our country numerous young men who have ample means for entering largely into this branch of business, but who are too little enlightened in regard to its nature, and refrain from industry, and suffer their capital, even with great losses, to remain dormant. We have others, too, who are without capital, and have a remarkable tendency towards the study of the practical sciences, of which we all feel the need in our actual or our future occupations. The latter class of young men would be incalculably benefitted by this course of education, and might be usefully and profitably employed as civil engineers, as directors of establishments, as well as teachers and professors in our colleges and schools.

In order that agricultural industry may develop itself throughout our country, it is necessary that our practical studies should enter into our manners; and this to such a degree, that each capitalist may find, either in himself or around him, able counsel. We should break down the barrier to every species of industry, and by leaving every man to enjoy the fruits of his own labour, undiminished by the exaction of a rapacious government. Let these principles be the immovable basis of our political economy. Our commerce and our manufactures should be defended and cherished like the sacred soil of our Republic. With means so ample and unembarrassed, we should give more enterprise and extension to works of domestic improvement. A taste for agricultural pursuits should be inspired, and new impulse given to public spirit. Institutions should be established, which, by assimilating the feelings of our citizens, may strengthen that union which is the bulwark of our national independence. Already the influence of our character far exceeds that of our strength, and our claims to the rank of a primary power, are admitted by the whole world, whose attention daily becomes more and more fixed upon our conduct. A great example is wanted by mankind—from us they demand it—and the cause of universal liberty is interwoven in our actions.

I have the honor to be, very respectfully, your devoted servant.
D. JAY BROWNE.

Gauge Wheel for the Plough and Ruta Bagas for Hogs.

J. Buel, Esq.—Dear Sir,—In your April No. of the Cultivator I noticed an article captioned "Help one another," and I can think of no way that I can better help my fellow husbandmen than by recommending to general use the gauge wheel on the plough.

Good ploughing I consider the first requisite in good husbandry, and yet many perform that part of their labor in a very slovenly, imperfect manner.

The article above mentioned, I view as a very important addition to the plough. The wheel should be 8 inches in diameter, and may be made from a plank 3 or 3 1-2 inches thick, with a bevel from near the centre to the outside, reducing the thickness to 2 inches. The tire may be made of common band iron. Bore an inch hole in the centre, place in it a box, reducing the hole to half an inch, which is to receive a bolt on which it revolves. The wheel is confined in iron bars or braces, one on each side of the wheel and beam. The braces should be placed in perpendicular form from the wheel to the beam, a little back of the clevey, through each of which should be three or four holes, and fastened to the beam with a bolt passing through it, with a screw and nut, with a handle, so that it may be easily altered, according to the depth you wish to plough, and from the wheel backwards, angling, to meet the beam a little forward of where the coulter should be put on, and fastened the same as the other ends. They should be 1-4 or 3-8 of an inch thick and one inch wide, so that it may be used among stumps or firm stone without danger.

The advantages of the gauge wheel are numerous. Any one who has ploughed old land in a natural and uneven state without it, knows that it is very difficult to turn the land evenly, all over. With it, it can be done with perfect ease. By having the chain good length, you can enter all the hollows and turn the furrow well on the knolls; whereas, without it, the plough will invariably run so deep on the knolls as to leave the furrow edgewise, and ten to one it will turn back after you. Also, in ploughing where you ascend and descend, it is very beneficial, as the plough will run no deeper down than up hill; and if you wish to plough with three horses abreast, it keeps the heft of the whiffletrees and traces from urging the plough too much onto the point; and while I am here, let me just state, for the benefit of those who may wish to plough with three horses, that you can have a plough built with a play of one inch in the mortice of the beam through which the handle is put, which fill with a wedge, that when on one side of the handle will give it land enough for a single or common team, and when on the other none too much for three horses abreast. But to return. The gauge wheel is of great benefit when you wish to use four horses, as the forward pair can draw direct on a line from the end of the beam without affecting the running of the plough. Finally, it makes it much easier for any team, easier for the man that holds, and does the work far better. The whole expense does not exceed $2, and the only wear is on the bolt and box in the centre of the wheel. My neighbors who have used mine have each one of their own. "To try it is to be convinced." Therefore, to every farmer I would say, get you a gauge wheel.

With regard to ruta hagas for hogs, I would barely say, that I kept my store hogs, ten in number, entirely on them, raw, for more than two months in the last winter, of which I raised some with good success the last season. One and a half bushels per day kept them well. They would weigh probably 150 lbs. each.

If you think the above worth your notice, you may do with it as you think proper, and I am content.

Your obd't serv't,
L. A. BEEBE.

Lima, Livingston Co. 7th May, 1838.

New kind of Wheat.

Sir—Last summer I received from Portugal a sack of wheat, the nature of which you will see by the subjoined extract of the letter that accompanied it. I send you a small parcel that you may appropriate it as you may think best for the benefit of the public.

"*Lisbon, 11th April.*

"They have here a description of wheat which I think may answer your purpose, called Trigo Tremeg, or Trigo de sette somanas, for its being cut sometimes seven weeks after it is sown. It is only grown on the low marshy lands which are under water at the time of sowing the common wheat, or upon the higher lands, when the spring rains have been so violent as to wash the seed out of the ground, by no means an uncommon circumstance here. On the marsh lands it gives regularly a very fine crop; on the hills it is uncertain, for if the hot weather comes on rapidly it gets burnt up before it has strength to resist the sun; if it escapes that risk, it usually gives a more productive crop than the common wheat. It is usually sown in the beginning or middle of May, and reaped in the beginning of July."

Yours very obediently.
L. ASHBURNER.

Stockbridge, Mass.

[Mr. A. will please accept our thanks. We have distributed and sown the wheat, and will hereafter give the result.—*Con. Cult.*]

Mode of disposing of loose Stones, &c.

Plattekill, Ulster, 4th mo. 13th, 1838.

As there is much valuable land in this section of our country rendered almost useless by the abundance of stones that cover the surface, it may be asked how I get rid of them? I answer, there is a lane across my farm which is not at all injured by being covered two or three feet with stones, and the same gravel that covers one foot of stones would cover three, provided the large ones are laid in the bottom and the small ones atop. The same remark will apply to roads, one or more of which is contiguous to almost every farm, and would be rendered better by filling the hollows with stones and taking earth from the hills to cover them.

After clearing my rough land of stones, from the many encomiums on the ruta baga contained in thy valuable paper, I am induced to believe that to be the most likely crop to pay the expense, but it wants manure to cultivate it successfully, and I want all my stable and barnyard manure on my corn field and meadow. Are there not other ways of accumulating a heap of manure sufficient for an acre or two of ruta bagas on a farm of 100 acres? Every cleanly woman uses a barrel or more of soap in a year, and makes much rily water, by cleansing her floors, which, with the soap suds, is thrown out near the kitchen door, and forms a stagnant pool. Its miasma is prejudicial to the health of the family, and the cleanliness of the wife is put to the blush by the slovenliness of her husband.

Now every house is, or should be, on higher ground than some contiguous part of the farm. I would suggest the plan of making an under drain from the house to some low spot, put a fence around it, and a shelter for hogs, which, during the summer, may as well be confined at night as to be in pasture; in this yard throw weeds from the garden, straw, swamp earth, and no disadvantage would result from mowing many a field of St. Johnswort and daisies when in blossom, and consigning the crop to this yard. Now, lest I should tire thy patience, I will write no more.

Jesse Buel. S. HEATON.

A good suggestion.

Wheatland, April 25, 1838.

Dear Sir—I was highly gratified on seeing the proceedings of the State Agricultural Society and Convention. I think the appointing of committees to report on the various items of husbandry is an excellent plan, and if continued, cannot fail of being very useful, and if there were two or three committees to report on each of the most important subjects, it would be better, as there is difference of opinion and practice on the most of them. We could then compare them, and be better able to judge which was right. Being some time ago in conversation with an intelligent gentleman, (who takes great interest in agriculture,) on the best plan for its advancement, he suggested the employment of a competent person to visit the various sections of the country and spend a day or two in each neighborhood, and thus ascertain what each are doing, and wherein they are deficient, and give it to the public through the medium of our agricultural journals, *without giving individual's names.*

I thought that the plan would be an excellent one; if performed by a competent person, it would elicit volumes of useful information.

April thus far has been very cold, with severe frosty nights, which has very much injured wheat on most ground, but dry soils as yet stand it well, which proves the great advantage it is to the cultivator to *ridge* and screen the ground so as to keep it dry.

WM. GARBUTT.

Remark.—The suggestion of our esteemed correspondent is a good one, and is virtually recommending an agricultural survey of the State—by which a knowledge of the best practices of every district, and of every good farmer, may be made known to, and adopted by, every farmer in the state who is desirous of improving his condition. There is no doubt but this important subject will engage the attention of our legislature,—*as soon as personal and political matters will permit them to attend to those of a primary and public nature.* As agriculture is of no party, she cannot expect her interests to have precedence of those which promise personal or political aggrandizement.—*Conductor.*

Mineral Manures.

Although there is much to please and interest the mind in practical farming, yet devoid and apart from the theory, it is little else than a routine, suited to the capacity and ambition of uncultivated minds. An active and enlightened mind seeks to understand the cause and effect—to apply the sciences; in short, it is restive, until the queries embraced in agriculture, are disposed of and determined upon sound philosophical principles. 'Tis this constitutes theory! and 'tis this theory, that unfolds a world of beauties to the scientific agriculturist, of which the mere prejudiced practical farmer, the mere tyro and novitiate, must remain ignorant, and that too, of the highest branch of the profession which he follows.

The improvement which has been effected within the last twenty years in several of the eastern counties of Pennsylvania, (and *especially* in Chester,) is almost incredible. And the whole is mainly attributed to a regular and judicious use of lime as a manure. To me, it has been matter of astonishment, to find this inestimable restorative meet with so little favor in the minds of the conductor and correspondents of the Cultivator. My farm is situated in a district of secondary formation, and the soil is principally calcareous, yet I have seen the most surprising beneficial effects attending the free use of lime and plaster; the latter apparently reacting on the former, and consequently, the greatest benefit is derived by using them together. The crops, not only on my own farm, but on others in this vicinity, have been doubled by a free use of mineral manures. When a farm has been improved so as to produce heavy crops, there will be such a corresponding increase in the quantity of stable manure as to insure its future fertility.—I look upon the immense beds of limestone in this region as an inexhaustible store, designed by the wise Governor of the World to keep up the strength of the land, in all time to come. I regard the limestone of Pennsylvania as a mineral, which will confer more real benefit upon posterity than any of her other mineral treasures. The aid which it promises to contribute to the support and improvement of her agriculture cannot be easily overrated. Some idea may be formed of the estimation in which lime is held here as a manure, by the fact, that farmers come from 25 to 30 miles, i. e. from Maryland and the poor district of primitive formation in the southern part of Chester county, bordering on the Maryland line, to my lime-kiln and others in the neighborhood: the lime costing those farmers twenty-five cents per bushel when delivered. To the farmers in that quarter, lime is the "anchor of hope;" *there* it has already made the barren and desert place *glad*, and is fast putting a new and improved face upon the country. The farmers, *even there*, with this far fetched means of improving their land, prefer bettering their condition by liming near a good market, rather than migrate to the exuberant soil, and realize the utopian dreams and fairy tales of the "far west."

On part of my farm, 300 bushels of lime per acre have been applied within 30 years, at the rate of about 100 bushels per acre at a dressing, and always put on fresh, and slaked, then immediately spread. I am not inclined to believe that lime should become carbonated before it is applied. I adopt Sir Humphrey Davy for my prototype, in every case involving agricultural chemistry. I shall be encouraged so to do, until some modern wiseacre can clearly demonstrate that Sir H. is wrong. Doubtful points in Davy's theory have become demonstrable truths with me, after being aided and enlightened by the lamp of experience. Lime, in its fresh caustic state *only*, while an alkali, acts as a decomposing agent in the soil, rendering vegetable substances soluble—but when a mild carbonate, it operates only like marl, in improving the texture of the soil, according to Davy, whose authority is unquestionable, and the theory, at all events, may fairly challenge contradiction; hence the advantage of applying lime, like stable manure, in its fresh state.

With regard to the theory, or the manner, in which gypsum operates on vegetation, an accidental circumstance which occurred in my practice and under my own eye, goes further to establish the truth in my mind, than all the ink that has been spilled on the subject; even the adopted theory of Prof. Low and British Husbandry to the contrary notwithstanding. In April, 1832, I sowed a ½ bushel of plaster on a small piece of land in the middle of a wheat field, for experiment,—in order to ascertain whether the plaster would have the slightest effect, even of changing the color of the wheat,—the result answered my expectations; there was not a shade of change in the color of the wheat in the future stages of its growth. In autumn following, the same field was again ploughed for wheat, and the plaster of course turned down, the field was deeply ploughed, say seven or eight inches—the spring following the field was sown with clover seed; the secret *then* was speedily developed; when the wheat was cut in harvest the growth of clover on that same land which had been sown with plaster was so luxuriant as to interfere with the cradle in cutting the wheat. Soon after harvest, the clover on the said land flowered, and a heavy swarth might have been mown on it in September following. The adjacent parts of the field, with the same soil and culture, exhibited a sickly contrast. In the autumn of 1833, the clover on said land was trodden down by stock, returning manure to the soil, and by that means the plaster *indirectly* prepared the ground for a sure crop of wheat.—This one single and simple fact, serves to overthrow the theory that plaster must be sown on the plants, to be absorbed through the pores of the leaves—attract moisture from the atmosphere, &c. This mooted point I consider settled, and the soil and roots made the laboratory instead of the leaves and the atmosphere.

Although my agricultural career has been only short, yet the great object, *improvement*, has been ardently and zealously pursued—sufficiently, indeed, to create a most utter and implacable abhorrence against all vague and unfounded theory, which is the bane of the agricultural press. The mere conjecture of a writer, if in error, will do no harm; but 'tis the *positive* declaratory assertions, where wrong, that do mischief, inasmuch as many believe and adopt what they read.

Quere. Why is it that lime and plaster act much more efficiently when both are applied to the soil, since the base of *both* is lime?

WM. PENN KINSER.

Springlawn Farm, Pequea, Lan. Co. Pa. April 25, 1838.

Planting Corn and Potatoes.

Mark out the field (large or small,) one way two and a half feet apart, then plant two of these rows with potatoes, and two with corn, alternately. Both corn and potatoes to be planted fifteen inches apart between the plants or hills. Plough among the plants only one way, or any other process of horse hoeing in the same direction, not only cleaning and pulverising the soil, but laying up the earth to the potatoes, so that very little hand hoeing is necessary; and whatever the *produce* may be, the *number of plants or hills* is at least four, often five or six times, greater, than common planting by the acre. The philosophy of this mode of planting is, that the potatoes do not shade the corn any, and every row of corn is an outside one, so that it has light and air in abundance, and the potatoes are not hurt by the partial shade of the corn. I am a Scotch farmer.

J. Buel. WM. SMALL.

A too Common Case.

New-Scotland, April 18, 1838.

Mr. J. Buel,—Sir,—Having been a constant reader of your valuable paper, the Cultivator, since its first publication, I have invariably found you quite anxious to better the condition of the agricultural community generally. We New-Scotland farmers, many of us, are like the man who held the six-pence so close as not to see a dollar at arm's length. Our practice is as follows: if the land be nearly exhausted, to plough and sow the more, to obtain the greatest possible quantity of grain for market as soon as possible—to take crop after crop of small grain, and apply no manure, (except perhaps plaster) as long as a medium crop can be obtained—to reduce the stock in proportion to the quantity of hay and grain that may be on hand at the setting in of winter. The consequence is, a diminution of the quantity of manure, the stock so sparingly fed as to be quite unprofitable, and the farmer discouraged. You are no doubt ready to denounce these practices as bad, yet there are two causes, (and perhaps more) which go to confirm them; the customs of our fore fathers, having forgot that it has fallen to our lot to renovate a worn out soil, and the want of sufficient capital. With regard to my own practice, I must confess, I am robbing my land of its just due every year for the want of capital. Every ton of hay and straw, and every bushel of grain which I raise, should be consumed on the farm for ten years to come, at least. I am of opinion that had I kept all my produce of last year, ground the grain, and chopped the hay and straw, I could have kept twice the stock, and this rule may be applied to all my neighbors.

With regard to the foregoing remarks there are perhaps some exceptions, yet they apply to New-Scotland too generally. It is evident, then, our condition, as farmers, needs to be bettered, and if you think we need skill more than capital, (as we know you can impart it,) we shall look to the pages of the Cultivator.

W. M.

To relieve choaked Cattle.

Agawam, Hampden Co. Mass. April 24th, 1838.

Judge Buel,—Dear sir,—Observing in your valuable paper several communications on relieving choaked cattle, I take the liberty to state a case that came under my observation, which was as novel to me as it was efficacious. A neighbor of mine called on me one morning, a few years since, to assist him in relieving an ox of his that was choaked some time during the night, in consequence of breaking into an orchard; the ox was much bloated and in great distress, and it appeared he could not live many minutes. While making active preparations to relieve him, an elderly lady belonging to the family emptied part of the contents of a small snuff box into her hand and applied it to the nose of the ox; the relief was almost instantaneous, the bloat rapidly diminished, and the ox five minutes after ate some hay laid before him. I never heard of the remedy before, nor have I known it tried since, but in that case it was effectual.

Yours respectfully,
JONA. E. FERRE.

Plants exhaust moisture.

Judge Buel,—Sir,—In Mr. D. Tomlinson's communication in Cultivator, No. 2, vol. 5, on sowing grain early and feeding it off, he presents one idea, which I think is an error, and has a bad tendency. He recommends sowing grain early, (so do I these cold seasons,) so that it *"should come forward, shade and protect the ground from becoming too dry by early drought."* I suppose, from your remarks, which follow, that you either did not notice the above quotation, or else you are of the same opinion, that ground covered with vegetables will not become as dry in a drought, as it would if it lay naked. If vegetables do protect the ground from drought, then we cannot differ from our neighbor, who, in a dry time, remarks, that he shall not hoe his corn and turnips until it rains; he wants the weeds to shade the ground and keep it moist, or *"shade and protect the ground from drought."* As many farmers suppose that the shade of trees and vegetables keep the ground from becoming as dry, in a dry time, as the naked ground, I would mention that experiments, as well as reason, has satisfied me to the contrary.* I have found, by digging where the ground was equally loose or mellow, in a naked summer fallow, and corn field, where the corn nearly shaded the whole ground, in a very dry time, in August, that the ground in the latter, was at least a hundred per cent the dryest. The reason for this is so obvious, that it needs no explanation from me, and I offer none, unless called for. If Mr. Tomlinson should *"engage again in farming,"* and examines his grounds in a drought, to find where they are the dryest, I think he will find it to be in his upland meadows, or under the shade of a tree in his meadow, (I mean to except roads and other hard trod ground,) if it is a little before haying.

Yours respectfully,
WM. BURNHAM.

Madison, April 28, 1838.

Force of Habit.

Chillicothe, Ohio, April 11, 1838.

J. Buel, Esq.—Sir,—The soil in this Scioto valley is naturally so rich, that our farmers have heretofore considered that there was nothing more necessary on their part to ensure a crop than merely to put in the seed, and bestow upon it a small amount of *rough* working. But we find, tho' the country is but about forty years old, this mode of culture has been such a continual draw upon the native strength of the soil, that manifest symptoms of exhaustion appear. This is causing some farmers to think upon the necessity of altering their mode of culture, and seeking for new lights upon the subject. But this waking up to a consideration of their true interest and that of the country, is not general among our farmers; there is but here and there one who has been brought to think upon the subject; hence the small number of subscribers to your valuable paper, and the scattering manner in which they are sent you.

It is a hard thing to break through ancient prejudices and habits. You ask a Scioto grazier how much corn it costs him to fatten an ox—he will tell you from 75 to 80 bushels. You question the necessity of expending that quantity upon an animal, and his economy in feeding, he will say to you, I have been engaged in feeding cattle for more than 30 years, and can be taught nothing respecting the business. To another, who practises no rotation of crops,—you say to him,—by taking off a crop of corn from your land year after year, burning the stocks, and neglecting to put any manure upon it, you will exhaust the soil and impoverish your land. He will reply, "I am an old corn raiser, and perfectly understand the making of that crop."

Light must be let into such minds by degrees; and I know nothing better calculated to lead farmers to thinking upon the subject than reading the Cultivator.

Very respectfully, &c.
NATH. SAWYIER.

On steeping seed Corn.

To prevent birds from pulling up or insects from destroying corn when planted, soak the corn 24 hours in a solution of salt petre and warm water; then, after draining off the water, take three parts tar to two parts of fish oil, warm, and mix them together, and put the mixture on the corn, stirring the corn until the mixture adheres to and covers the grains; after which it may be rolled in plaster, lime, or ashes, to prevent the grains sticking together when dropping. It is thought the tar prevents too much wet, after planting, from rotting the corn, and the oil prevents too much dry weather from drying the tar and thereby forming a crust around the grain that a sprout cannot get through, but both together make the mixture of a proper consistency that retains the moisture, renders the covering soft, and admits the sprout to get through. The above method has been tried a number of years by Mr. Ephraim Clark, a highly respectable farmer of Westfield, N. J., a number of whose neighbors also have tried the same with beneficial results, rarely having had to plant their corn over prepared in this way.

N. B. The same preparation answers well for Lima beans.

The above method was communicated to me by Mr. Ephraim Clark, who gave me permission to send it for publication.

Yours, &c.
WILLIAM MARSH.

Rahway, April 24, 1838.

Tonawanta and Tuscarora Hogs.

Tonawanta, 27th March, 1838.

Sir,—I notice in the extra of this month, which has but just reached me, among matters both sage and interesting, the very excellent report of the State Agricultural committee on swine, in which I find that you honor our young town in the name of a *distinguished* breed of the grunting gentry. We take the affair quite as good humoredly as it is there represented, and can only regret the "non-accompaniment of the sketch terrorum," as a finish to the no less just than comical picture. We hope it may yet be found, and grace the columns of your admirable journal as an *eschewing* beau ideal, for all future pig breeders. I suspect, however, that when the said portrait does appear, it will find many a faithful original, not only in Tonawanta, but where-ever the Cultivator may happen to circulate, be it in the forests of the north, the settled regions of the east and south, or the wild prairies of the west, and alike recognized, a wandering, squealing, grunting, raw-boned, thick-skinned herd of Ishmaelites—profitless to their owners and a nuisance to their neighbors, whose hand, or rather *snout*, is against every man, and against which every hand in the land should be indiscriminately raised.

Thus much in corroboration of the Tonawanties.—Allow me now to regret, that the committee had not extended their researches a little further in our good town. They would have then found, through the spirited exertions of a few individuals, another breed grown up among us, that I, at least, think the very perfection of swine, and that will prove to hogs, what the Durhams have to cattle, viz. combining in a very eminent degree the best qualities of all others. These also bear an aboriginal name, the noble sounding Tuscarora, and have been found mainly by a judicious crossing of the improved China with a very superior breed from Canada, and a slight touch of the Berkshire, giving them nearly the fineness of bone, the quietness and aptitude to fatten, together with the delicacy and sweetness of meat of the China, and a trifle more than the size, and an equal goodness of ham, of the Berkshire. They are beautifully spotted, of a clear black and white, the colors showing about equally,—are fine in the head, small ears, short legs, long, broad and deep bodied, and square lady sloped sterns, being in this last point, in my humble judgment, a very handsome contrast to the Berkshires.

The tenants of the Hon. Stephen White and A. B. Allen, Esq., rear them in the greatest perfection, but thus far have been rather chary in offering them for sale, preferring first to tolerably perfect the breed. Mr. Allen now proposes to part with boar pigs. He has also a stock of the improved China and Berkshires, so that gentlemen addressing him may be sure of a choice in the only breeds that are really worth cultivating, and I will venture to say as fine animals as can be imported or found in any other part of the country.

Thus, sir, having taken up the cudgel in an amateur whirl on behalf of the productions of our flourishing young town, and, as I hope, done the numerous readers of the Cultivator some service, in introducing to them, for the improvement of their own stock, a new variety of the honorable, grunting fraternity.

I remain, very respectfully, your ob't serv't. A.

P. S. 6th April. Since writing the above, I have had a look at the Cultivator of this month, in which I see a real racer, mounted over a fat Berkshire. He certainly is a *caution*, as we say here in the west, and gave us many a hearty guffaw. Pray, sir, is this the "Tonawanta sketch?" If not, let us have it, as I think our varied breeders here can match you for any thing pictured, be it *fat* or *lean*.

Reclaiming Swamp Land.

Glassboro, N. J. April 24, 1838.

Dear Sir—With your permission I will avail myself of the present opportunity to thank you for the suggestions contained in the March No. of the Cultivator, in reply to my queries respecting the improvement of my worn out lands. If it will not tax your patience too far, I will again call your attention to this *to me* most interesting matter. My experiment with the ruta baga has been most satisfactory. My milch cows, fed upon nothing but very indifferent hay, with a half bushel of turnips cut tolerably fine a piece, given twice a day, make butter, which, for color and flavor, I think, will not suffer in comparison with that made from the best clover pasture—while their appearance is so sleek, notwithstanding their having been exposed, without any kind of shelter, to all the storms of the past winter, that the question has been asked by others, have they not been fed on grain? This season, I am going to try to raise double the amount I did last.

But the matter I had more particularly in view when I commenced this, was to ask your advice in regard to reclaiming a piece of branch meadow, containing about twenty acres, situated on a part of my premises. This meadow lies at the head of Prince Maurice's river,—once part of an extensive swamp—and has at this time a soil about six feet in depth, composed of alluvial deposit. Twenty-five years ago this, with the rest of my farm, was in a fine state of cultivation, producing heavy crops of valuable grass. But it is now a waste, covered with a solid mat of moss, partly overgrown with bushes, with scarcely a spear of fine grass throughout its whole extent. Its only ditch is cut nearly through the middle, following the serpentine course of the original stream; the whole is now wet and miry. The bushes I know what to do with—but how am I to get clear of this infamous moss, which now holds such entire possession? What plan shall I pursue in draining it? And when reclaimed, how is it to be got into grass? Any information respecting the above, will be gratefully received by

Yours, E. C.

Remark.—Water—excess of water—is the undoubted cause of infertility. It probably comes from the higher grounds, and has to pass to the central ditch for an outlet. If our correspondent will ascertain its source, and conduct it off before it saturates his six feet soil, and will clear off the moss and bushes, and stock it with grass seeds, there is no doubt but it will again produce valuable crops of grass. Let a good under drain be made upon the borders adjoining higher grounds, to catch the water and lead it into the main drain; and if the wetness continues, make lateral drains; and if the water comes from spouts or springs on the flat, the source of the evil must be sought out, and the remedy, a drain from it, applied. Make the main drain straight, at least four feet broad at the surface, and three to six feet deep.—*Cond.*

Agricultural Books—Ruta Baga.

Unionville, April 7th, 1838.

J. Buel, Esq.—Dear Sir—Permit me to avail myself of this opportunity to convey to you my own and the thanks of our Agricultural Society for your kind assistance to me in procuring books for our library when in Albany in 1836. We should be glad to see in the Cultivator a notice, from time to time, of such publications as you would consider a valuable addition to an agricultural library.* We are adding some few volumes to our library, as we have opportunity, but we find it very difficult to procure suitable books to any extent for such a library, and still more difficult to get farmers to read them when procured.—Nothing that has ever been introduced into our agricultural society here has met with more opposition than the introduction of agricultural books and periodicals, and it is only within these two years past that the one or two persons that have advocated it these eight years past could get a majority to consent to it at all; and we believe that the same amount of money has never been expended by the society in a way to produce as much lasting benefit to the community; and the managing committee of our society, which is now called the District of Johnston Agricultural Society, have become so far sensible of this, that they have determined still farther to increase the means of information, by placing in the hands of each member of their society, (that pay two dollars a year or upwards,) a monthly agricultural paper gratis, and it is in furtherance of that determination that I am authorized by them to make the above order. We have ordered papers from other places, and the probability is, that we may be under the necessity of troubling you with further orders before the termination of the year. Since we have adopted the plan of diffusing the means of information, we find it far easier to get farmers to introduce new plans of improvement in their agricultural operations. Notwithstanding the slowness of our progress in the scale of agricultural improvements, in comparison with what is being done in some parts of Europe and the United States, yet it ought to be matter of some encouragement to us, that by making a seven years comparison we can discover that we have progressed a little. Our Society was formed in 1830, and as was usual at public meetings at that time, the brandy and wine bottle was brought in abundant requisition, and after the close of business, the meeting was broke up in dispute and disorder. But clear cold water has now taken the place of the brandy and wine bottles at our agricultural meeting dinners, and generally supersedes the use of whiskey in the field; and we expect for the future to bring clearer heads and sounder understandings to our assistance in hastening mental and agricultural improvements. Six years ago an attempt was made by the managing committee to introduce the culture of the ruta baga, by offering a small premium to any one who would cultivate a quarter acre, but not an individual could be induced to make the trial. But last year a number of pieces came in competition, and received premiums. My own received the first, and yielded at the rate of about six to seven hundred bushels per acre, and this year there is a prospect of considerable being cultivated, if seed can be obtained. Mangold wurtzel would receive a trial also, if we could get seed.

---

* Mr. Burnham is correct.—*Con. Cult.*

* We are not aware of any recent publications on American husbandry, except our agricultural periodicals. If Chaptal's Agricultural Chemistry, Low's Elements of Practical Agriculture, and the Farmers' Series, published by the British Society for the promotion of useful knowledge, were not included in our former list, we can recommend them as valuable acquisitions to an agricultural, or farmers' library.

J. G. BOOTH.

Economy of Manures.

Hagerstown, April 25th, 1838.

To Jesse Buel, Esq.—Dear Sir—* * * In speaking of 40 loads of manure to the acre for corn, does Agricola mean cart or wagon loads? I find a much smaller number of wagon loads of long manure from my farm yards, (so constructed as to retain all the *lye*, and the manure completely saturated with the lye,) a handsome dressing for corn. On the subject of manure, I will observe, that my system is, to carry out from my farm yard two crops a year. The first crop is made chiefly from straw, during the fall and winter, and carried out in March, for my corn crop. I then, immediately, commence feeding my corn stock fodder, brought in and stacked near the farm yard, so as to be fed and littered away in my farm yard, where my cattle and horses are kept until the middle of May, or the crop of fodder is consumed. By keeping my cattle up in this way until late in May, I find their manure, mixed with the corn stalks, produces fermentation and decomposition by the middle or last of August, so as to enable me to use the manure to great advantage on my fallow fields as a top dressing, to be harrowed in with the seed wheat. This year I shall keep my cattle, &c. in my farm yard after they have consumed the corn fodder, and feed them on clover, cut and brought into the farm yard and fed from racks. This, I think, will greatly enhance the value of the manure, expedite fermentation, and tend greatly to decompose the corn-stalks. My corn field will be an old clover field, mixed, I regret to add, with too great a quantity of wire or blue grass, (to get rid of which I wish you to instruct me.) The sod is turned under, deep, in the fall. In the spring, the spring crop of long manure is applied, and the ground cross ploughed, throwing the long manure below, and the sod turned under the last fall, a great portion of it is brought to the surface, which, by the use, then, of a heavy harrow, twice applied, is well mixed with the soil, and my land, I find, in good condition; and by the use of the Cultivator, frequently used during the summer, my crop of corn will be productive, and the land put in fine tilth for small grain. I have been surprised to find the sod turned under the preceding fall, on being brought to the surface and exposed in the spring, easily pulverized and incorporated with the soil, and so decomposed as to furnish, I would suppose, fine pabulum for the young corn.

The above remarks, hastily thrown together at a leisure moment, are intended to elicit your opinion. A short letter in reply, (or full on every subject, if you can spare the time,) will be esteemed a favor.

I am, sir, very respectfully, your ob't serv't,

F. TILGHMAN.

Remarks.—We are inclined to think that cross ploughing for corn both wastes the fertilizing matter of the sod, and encourages the growth of blue grass. We venture to suggest, that the spreading of the spring crop of long manure in the spring upon the clover ley, and *then* ploughing it under well *once*, would be a preferable course. If the sod is found to decompose in the winter months, it will do so much more readily in the spring, particularly if aided by the leaven of long manure. Mr. T. will find his queries, in regard to preserving corn, and to what constitutes a load of manure, in a measure anticipated in other columns of this paper.—*Cond.*

To the Dairy Women of our Country.

New-York, April 25th, 1838.

The undersigned, dealers in butter and cheese, would call the attention of the manufacturers of these articles in the middle and western part of this state, to the existence of general and just complaints in regard to the quality and condition of both butter and cheese made in such sections, together with the packages. In view of this fact, and to encourage an improvement that will restore and increase the reputation formerly enjoyed by producers of these articles, they would respectfully submit to their consideration, the following views, relative first to the manufacture of cheese:—In all cases, the milk and rennet should be perfectly sweet; as much of the animal heat should be evaporated from the milk as time will admit; when the curd is properly produced, break it up very fine, cook it well, but do not heat it so much as to start the oil in the curd; season it with clean fine salt, pure from lime; put the cheese in the press cool; press it hard, in order to extract all the whey from the middle before the outside closes tight; continue to press for two days; from the press put a dry cloth over it for a few hours, until a rhind is formed—then put on Annatto, dissolved in strong lye; cover again with cloth until next day; after the cloth is removed, put on a thick strong coat of melted bees-wax and lard, or butter; get a bright smooth surface, and keep one, by constant rubbing and turning, until the cheese is perfectly cured. When put in the casks, let it always be done in cool dry weather. All cheese should be slightly colored with Annatto in the milk, and such as do not exceed fifty pounds in weight, should be made a bright orange color—cheese of this description being generally in good demand for the southern markets. Finally, there should never be any late cheese. In no case should cheese be sent to market made after the 15th day of September, nor should it be sent even thus late, unless the utmost pains is taken with it, and unless well cured by a fire. It is of the greatest importance to the dairying interest, that these rules, in regard to late cheese, be strictly conformed to: for this kind of cheese not only destroys itself and greatly injures the market for a good article at the present time, but should the practice of making and sending it be persisted in, it will eventually destroy the business. To prevent any loss to the farmer, the undersigned would advise them to make butter after the 15th of September. Butter made after this time always commanding a fair price.

2nd. Of cheese casks.—They should be smoothly and well made of good seasoned wood, not less than half an inch in thickness for small casks, and five-eighths of an inch for large casks: the heads of all large casks should be at least five-eighths of an inch in thickness, to prevent them from springing; the staves should be narrow, in order to preserve their places and keep the cask round; there should be always a fair bilge, with at least eight good substantial hoops, (maple hoops should never be used,); the quarter hoops should never be put down so low on the casks as to allow the staves to spring out when the head hoops are taken off; the other hoops should all be securely nailed.

3rd. Of butter.—In all cases where it is made from cream, it should be churned before the delicious flavor is lost, or any bad flavor is induced; avoid too much heat in the process,* as this causes the butter to be soft, and of fine grain, bordering on a waxy character; never fail to extract every particle of milk before it is laid down; season it with rectified fine salt, or ground solar salt, and work in no more of it than will be entirely dissolved—where any of it is left undissolved, it destroys that delicate rosy flavor which renders the article most desirable, and its value diminishes in proportion to the excess of salt—this being one of the greatest objections to western butter.

4th. Of the packages.—The undersigned would recommend two kinds, viz. firkins and Welch tubs.—The firkins should be made of seasoned white oak and walnut hoops. Where white oak is not to be had, they should be made of heart stuff of white ash, and hoops of white or black ash, or elm, of good shape, and perfectly smooth; have on at least ten good hoops, smoothly shaved; be perfectly tight, and contain 100 lbs. Welch tubs should be made of seasoned white ash, hooped with seven substantial split ash hoops, smoothly shaved, to contain 100 to 120 lbs. Both firkins and tubs should be soaked with a strong pickle, in order to saturate the wood before the butter is laid down, (but never put any salt at the bottom or on the top of the butter.) Great care should be taken to put it down solid; never fill the packages so full as to have the head or cover touch the butter, and always make a smooth surface on the top with the ladle. The tubs and firkins should be weighed, and the actual dry weight marked upon them with a marking iron in such a manner as not to be obliterated; and let them always be found accurate.

In conclusion the undersigned give it as their decided opinion, that the manufacturers of cheese and butter in the middle and western parts of this state, who will observe the above rules, and unite with the observvance a desire to make their articles of the first quality, after a little experience, will soon be able to compete with any part of the United States, both in quality and prices, at home or abroad. Possessing, as these manufacturers undoubtedly do,—one of the finest soils, and best adapted to grazing of any in our country, they may produce the article in the greatest perfection. On this, as well as other accounts, the undersigned wish to impress upon their minds the importance of this subject, and that the course recommended is the only one which will secure to them the advantages of a fair price and good reputation for their labor and pains.

On Steeping Seed Grain.

Ionia County Seat, Mich. April, 1838.

Sir—Having recently become a patron to your excellent and very useful paper, and in the last volume finding several communications upon the subject of steeping seed corn, from persons who have been unsuccessful and are adverse to the practice, I feel disposed to offer a little of my experience in its favor.

It is now some twenty years or more since I first inherited the practice (from my elder brother,) of steeping seed corn in a solution, of sal nitre, and have ever derived manifest benefit therefrom. One object of this communication is to relate the effects of this practice on a particular occasion, which, however incredible it may appear to some, is not the less true. Another is to encourage those unsuccessful steepers to try again and again—try on. In the spring of 1826, I planted twelve acres of corn on a green sward recently turned over; harrowed and the rows marked out, and as usual put my seed a steeping the evening previous to the commencing the operation of planting. Repeated experience had proven to me that if the planting was accomplished before the cold easterly storm commences, which visits our country between the 5th and 20th May usually, my corn was more thrifty, would better endure a drought, and be beyond the effects of early frosts; while the older farmers in my neighborhood, who waited for that storm to pass by, were sure to have a poor crop, when that storm was late, or a drought followed, as was sometimes the case. On this occasion the storm came on in the midst of the planting, and drove the men from their labor. The seed in a tub was brought home and put in the carriage-house, and in hopes the storm would pass off in a day or so, the liquid was not poured off, but remained with the seed until the germs had grown a quarter or three-eights of an inch; in this state the seed was emptied upon a piece of very coarse sacking, the corners of which were pursed over a hoop and fastened, and hung up to drain, where it remained for some days until the storm was over, when the planting was recommenced with this sprouted seed, the germs of the corn having become wilted somewhat and thereby toughened, so that they would not break off, readily satisfied me that the seed would grow; the planters being faithless, thought to improve the matter by putting in five and six kernels to the hill, instead of three or four, as I had directed; the first consequence of which was, that the seed was all used up before finishing the ground, when I knew there was an abundance. This was, however, kept secret from me until the corn told the tale, and I was obliged to pull up at least one-third of the corn so planted, and showing satisfactorily that the seed all came up.

My invariable mode in preparing the seed was to put the nitre into boiling water, that it might the more readily dissolve. As to quantity I was never precise, but as we Yankees would say, "guessed at it."—When the nitre was all dissolved, and I could bear my hand in the solution, I poured it upon the corn, and if there was not sufficient water to more than cover the seed, added more warm water, otherwise the swelling of the seed would soon cause a portion of it to be out of the water.

Should you deem this communication useful in what I esteem the very excellent practice of seed steeping, you are at liberty to make such use of it as may seem proper. Very respectfully, sir, your obd't servant,

J. Buel, Esq. TRYON.

---

* It has been found, that the *best* and *most* butter is obtained when the cream is about the temperature of 55°—and if the temperature is over 60°, the quality is inferior, and the quantity diminished. Hence, every dairy should have a thermometer.—*Conductor Cult.*

Deep Ploughing—Steam Engines—Wisconsin.

Buffalo, April 12, 1838.

My Dear Sir—Under the head of "good tillage," in your last number of the Cultivator, you have thrown out some most valuable suggestions as to the mode of ploughing. Your recommendation of *deep ploughing* is one that I have thought for some time, should be made a subject of special attention by agricultural papers, and *insisted on,* as the *great augmenter of nutriment for vegetables.* By breaking up the hard, compact earth, which sustains the vegetable mould, and disintegrating this indurated mass, the atmosphere, and rains, and dews, have access to portions of earth hitherto beyond its reach, and as you have conclusively shown, rapidly fertilize and render it capable of sustaining vegetable life. This increase of the *pabulum* of vegetables by the difference of the *mode* of culture, without addition of expense for *material,* and scarcely any of labor, seems akin to that of increasing the food of animals by steaming simply; the first makes *two* blades of grass grown where only one grew before, and the last makes each blade go twice as far; the result of the combined improvement of deep ploughing and steaming, giving as four for one over the common methods. These topics should be insisted on strongly and constantly, and whenever adopted generally through the country, farming will become what it really is, and ever ought to have been considered, not only the *first* and *noblest,* but the *most profitable* occupation of man.

This subject acquires great additional interest when applied to our western soil. With us, and throughout the great west, nearly all, (I think I speak within bounds in asserting seven-eighths at least,) of the land in the west, is what is called *clay,* having a clay sub-soil, with a large share of this earth intermixed with the super-soil. This is eminently the kind to be most improved by deep ploughing. This earth is so adhesive that it forms a perfectly solid mass, impermeable to water and the atmosphere in the slightest degree, and while remaining in this state, incapable of furnishing the least sustenance to vegetables. Yet this same sterile material, so worthless in its natural condition, becomes by proper cultivation, the most fertile and valuable, capable of producing, with proper additions of coarse manures, every variety of crop in the greatest luxuriance. *Deep ploughing* is the first and essential requisite for this, and now sir, how are we to apply the remedy? We have no plough that is at all suited to this object. "Smith's sub-soil plough" referred to, we have no description of, and know not where to obtain, till you, sir, do your subscribers the favor to direct them where they can be procured, or give a description so minute that any ingenious mechanic can make one. With this instrument, however, it seems to me a *steam propelling power* should be used, as the great additional labor to be done will require a considerable increase of power, which will render the application of steam peculiarly appropriate and desirable. Indeed from the great saving which steam would afford in this branch of husbandry, it is somewhat surprising we have not yet had even one successful *steam plough.* In the spring of '36, while travlling over the fertile praries of Wisconsin, I was struck with the perfect feasibility of the application of steam to ploughing, and of its great utility too, as I saw some eight or ten yoke of large cattle attached to an axletree, to which a plough was fastened, and this with no one to hold it, and only a single driver, was turning a furrow of almost interminable length, at a snail's pace, which it is almost impossible to quicken with oxen attached to a plough of any kind. There was nothing in this operation which was not perfectly mechanical, and coming within the scope of *machinery,* under competent management. For a large portion of the west, (with us as well as elsewhere, when the ground is clear of stumps,) and over all the level lands of the east, such as the large and fertile intervals of the Connecticut, in and about Northampton, where by a judicious municipal arrangement, fences are done away with, tracts of thousands of acres could be ploughed in a body by a single machine, at an expense of probably one-fourth the present cost of ploughing, and this too may be done with scarcely a perceptible increase of expense for any additional depth, and others by combining the two improvements, steam and deep ploughing, we obtain our great objects, *the fertilization of the soil and the large increase of vegetable product,* at an expense very much below that of the ordinary method.

Mr. Dutcher, of New-York, the successful competitor for the premium plough at the fair of the American Institute last fall, is experimenting on a steam apparatus, as I was informed when in the city last winter, but my search for his establishment was unsuccessful, and I know not what progress may have been made in perfecting one. It is to be hoped, however, it may not be deferred beyond the period absolutely required to complete it.

Allow me, sir, to suggest an idea or two which you can make of benefit to the community, though a little out of the path of *agriculture.* Cannot *steam* be used to a great extent in enlarging our canal by applying it to excavating machines, which will work perfectly well under water? I have used such a machine in some parts of our harbor, that with horse power would do the work at from six to eight cents the cubic yard. Could excavation be done as cheap even if the water were excluded?

In the long reaches of the canal, where locks were not interposed, could not a large saving be made by laying a slight rail-way on the tow-path for a locomotive, that could draw any number of boats attached to it, at twice the present speed, and perhaps one-tenth the present expense? Cannot some plan be devised of carrying off the smoke, cinders and steam, which are now the great annoyance of rail-road travelling? I believe it entirely practicable, by having large, stationary, horizontal pipes attached to the top of each car, to be connected when the cars are attached to each other, by *flexible* pipes, which can in a moment be joined, and through this continuous pipe the whole obnoxious effluvia from the locomotive would be delivered behind the train. In winter a pipe might form a part of the floor of the cars, and thus contribute essentially to the comfort of passengers. This alteration would allow of seats on the top, and thus enable travellers in pleasant weather to make a trip as agreeable as expeditious.

Can you inform me where any of the *genuine* Egyptian spring wheat can be obtained?

Excuse this discursive sheet; I should not have obtruded myself at this time on your attention, but for the purpose of requesting you to forward the *present* volume of the Cultivator to J. W. Conroe, P. M. Manitouwoc Rapids, Wisconsin Territory. We are beginning a fine settlement at and adjoining the mouth of the river in this fertile valley, which extends from Lake Michigan on the east to Lake Winnebago on the west, through which we hope eventually to have a navigation by the Fox and Wisconsin rivers, *now navigable* to the Mississippi; and this internal communication will be second to none other in importance in the west, combining timbered lands and prairie of unsurpassed fertility, copper and lead mines, pure water and a wholsome climate, soon to be filled with a dense, intelligent, active and thriving population, and *we want to begin this end of it right,* and know of no better method than to commence with your excellent publication and the Genesee Farmer. If your periodical suits the soil and climate, and I know of no objection to its answering for both, I think in five years you will have some thousands of subscribers in that territory alone.

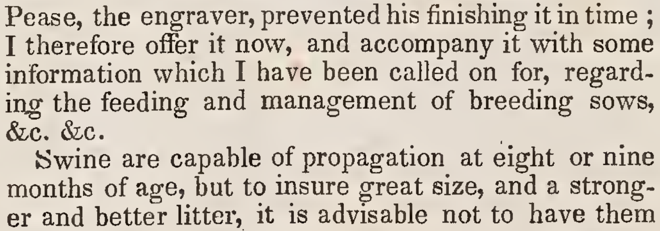
Very truly, your friend and ob't serv't,

R. L. ALLEN.

Judge Buel.

Treatment of Berkshire Hogs.

[Fig. No. 37.]



Mr. Buel—Sir—It was my intention to have had the above cut, a portrait of one of my Berkshire sows, at the head of my communication in the last number of the Cultivator, but the absence of Mr. Pease, the engraver, prevented his finishing it in time; I therefore offer it now, and accompany it with some information which I have been called on for, regarding the feeding and management of breeding sows, &c. &c.

Swine are capable of propagation at eight or nine months of age, but to insure great size, and a stronger and better litter, it is advisable not to have them come in, until after they are one year old. The boar should be used sparingly until he is eighteen months of age. The period of gestation is about sixteen weeks, so that two litters may be easily produced in the year. I prefer the months of March and September, for my sows to litter, as the weather is generally milder and less risk in rearing.

The usual produce, from my old Berkshire sows, is from nine to fourteen pigs—the younger ones from five to nine. When about to farrow, they should be put into separate pens, otherwise they may overlay or will mutually devour their offspring. Care should be taken not to let them get too fat; as experience having shown, that if they are in very high order, they will not produce as many nor as strong pigs. While suckling their pigs sows should not only be plentifully fed on nutritious food, but should be regularly fed, for if pigs are deprived of their proper nourishment while sucking, they will never arrive at the weight they would otherwise attain.

It is advantageous early, say when they are four weeks old, to accustom the pigs to feed from a shallow trough, on milk, corn meal, ground oats, barley, peas, or buckwheat; boiled potatoes or carrots, mixed with the above is also very grateful to them. This not only gives the pigs a fair start, but very much relieves the sows.

I have my troughs so constructed, that the pigs can be fed without the interference of the mother. (See my plan of a piggery in the first number, page 14, of the present volume of the Cultivator.)

At the end of a week or ten days after farrowing, they may be turned out of their pens into yards, for two or three hours on warm days, in order to stretch their legs, which is far preferable to total confinement.

The best time to wean pigs is when they are from six to eight weeks of age. They should be kept in styes having yards, or if possible, a clover patch for them to run in. Their food should be good; feed often and a little at a time, and as much as they will eat. Boiled or steamed potatoes or carrots, with a little corn meal, ground oats, barley or buckwheat, and where there is a dairy, mix with milk instead of water.

For making pigs grow fast, I never have found any food to compare with the offals of an hotel, or the slop of the dairy. During the weaning, great care should be taken in supplying them with plenty of sweet straw, and to keep them as clean as possible, so that they may always have fine sleek coats; a circumstance this, of such importance, that the want of it can never be compensated by the most plentiful supply of food.

This management is not peculiar to the Berkshire pigs, but will apply equally well to any breed. Sows may be permitted to breed till they are six years old; and the boar may be well until he has passed his fifth year, after which they may be fattened for pork.

For winter food for store hogs and breeding sows, I find roots admirably calculated, such as carrots or ruta baga, given them raw at noon and night and boiled or steamed with a small quantity of ship stuffs or buckwheat bran, mixed and given them warm in the morning. On such food, I kept from fifteen to twenty head during the winter, and I never had them in finer condition.

Charcoal, clay or rotten wood should be given them occasionally; also, a small quantity of sulphur should be mixed with their food, as often as every other week. Their boiled food should be seasoned with salt.

C. N. BEMENT.

Three Hills Farm, May, 1838.

Italian Spring Wheat.

Judge Buel—Dear Sir—It pains me to say that many wheat fields among us show no signs of vegetation; farmers are divided in opinion as to the cause; many impute it to the long continued cold in April, and severe freezing; others to brining *overmuch;* I incline to the latter opinion. Within a few days past, I took a sample of spring wheat from the mill—it had been screened and scoured in the smut machine—one parcel of it I covered with moist earth; another I put into brine, and after twelve hours, took it out and covered as before; the third parcel I put also into brine, it lay twenty-four hours, and then was sown. Of the first parcel, after five days, I did not find one kernel in fifty, but was firmly rooted and sprouted; of the two brined parcels, I did not find either sprouts or roots on a single kernel. Thus I have proof that admits of no doubt, that if Italian spring wheat be soaked in strong brine twelve hours, the principle of vegetation is destroyed. This fact ought to be widely disseminated. Other wheat, of a thicker epidermis may, for ought I know, grow after being steeped half a day in brine, but the Italian will not. I intend to experiment still farther, and ascertain the time that wheat will loose vitality in brine.

Respectfully yours,

J. HATHAWAY.

Rome, 12*th May,* 1838.

NOTE.

We will not pretend to conjecture *why* Mr. Hathaway's Italian wheat did not sprout after being steeped in brine; but we can state as an offsett, that we have soaked seed wheat in pickle, during twenty years practice, including the Italian, without the germinating principle having been destroyed, or apparently impaired. The practice has been general, and the above is the first case which has come to our knowledge, of its having proved prejudicial.—*Cond. Cult.*

Manures—Madder—Wheat—Butter.

Pleasant Township, Warren co. near Warren,
Pa. May 5, 1838.

J. Buel, Esq.—I have read the Cultivator from the beginning, and am indebted to it, for much of my limited knowledge of agriculture, having spent the prime of life in other pursuits. So important is this publication in my estimation that I would encourage the circulation not only among farmers, but all others, who have any taste for rural employment.

The husbanding of manures, and a judicious application of them, has been freely discussed, and has led me to turn my attention to this subject.—I am persuaded that many who are esteemed good farmers, are lamentably deficient in this matter. I think I can now save two loads of manure where I formerly saved one, with the same stock and fodder; and in the application, I have gained much useful information. I practice covering the unfermented yard dung under the sod, and with good success. I am a convert to a rotation of crops, and to root culture—both of which were first suggested by the Cultivator. I have better corn crops, and have improved in skill, in the matter of harvesting. I now cut up my corn, as you recommend. I use ashes applied to the hills.

I obtained from Mr. R. Bronson, 14 bushels of madder, *top roots*, which I planted on light sandy river flats, in the spring of 1836. The ground was rich corn ground, from which I had harvested wheat in 1835, yielding 30 bushels to the acre, the stubble being ploughed in the fall, was again ploughed into ridges or beds six feet wide in the spring, and each alternate bed set out with madder; the intervening beds being planted with carrots, onions, beets, potatoes, and some corn. In June, when all had begun to show themselves handsomely above ground, an unusual freshet overflowed a good part of the field; after it subsided, nothing was left except the madder; this was a little faded, but soon recovered its color, and since then, it has grown beyond any thing I could have expected, from the representation of Mr. Bronson. It has had two summers, and bids fair to cover the whole ground next fall, at which time I shall commence digging, and enlarge my plantation; and it is probable I could supply others with top roots, if applied for in August or September, a little before the time of digging. I intend to let the main crop stand four years.

I have this spring sown, (March 27,) two bushels of winter wheat, prepared as recommended in the Cultivator, No. 4, of the 4th volume, page 64. It is now handsomely up, and looks promising, though the weather has been cold and unfavorable. I obtained one bushel of Italian spring wheat, which I sowed in 1837, the produce of which I am much pleased with, and am now sowing several acres. I think it answers the recommendation given it.

It is said that the Russian mode of making butter is, to scald and churn the milk. In the 1st volume of the Cultivator, page 119, is a description of the dairy farm of Robert Smith, Esq. from which I learn "the cream is raised by steam, produces very sweet butter; it sells in market in summer at 31 cents, and in winter at 50 cents per pound." The butter-milk is represented as being more valuable, &c.

I do not practice the Russian, nor yet the steam method. But for fifteen years past have scalded the milk, as taken from the cows—after which it is set in a cool place till the cream rises. We esteem the butter to be much improved—the skim milk and butter-milk, being free from acidity, are more valuable for culinary purposes, and the trouble of scalding is more than paid by the facility of obtaining the butter by churning. On a fair, impartial trial of milk divided and half scalded, the other half not, in the winter, when all was cold—the scalded cream required thirteen minutes, and the unscalded fifty-six minutes churning; one pound of butter was firm and yellow, the other open, frothy, &c.

Very respectfully,
NATHANIEL SILL.

Indian Corn, Spring Wheat, &c.

Ripton, Vt. May 14th, 1838.

Jesse Buel, Esq.—Sir—In the number of the Cultivator for the present month of May, page 59, it is stated that Mr. Thorburn sold corn for Dutton corn which proved not to be Dutton corn, as the stalks grew large and were seven or eight feet, whereas the Dutton corn is of rather a dwarfish growth. This corn was probably sold to Mr. Thorburn, by some honest Vermonter, and was undoubtedly the Dutton corn of Vermont.

Not far from thirty years since, Salmon Dutton, Esq. a respectable farmer of Cavendish in this state, procured a new species of corn, and having raised a crop of it, and as it had a very large growth, and was at the same time earlier than the corn that was then generally raised in this state, and believing that the farming interest would be greatly promoted by raising it, in October of the same year he transported a large quantity of it in the ear, to the place where the legislature was in session, and distributed it to the members and others attending the legislature; it was thus distributed through the state, and took the name of the Dutton corn. I took an ear of it and planted it the next season; the stalks grew seven or eight feet high, and were large in proportion to their height. The ears were longer and much larger than any I had before seen, having from 12 to 18 rows on an ear. The cob was very large and the kernels very small and not so flat as the kernels of other corn; and many of the ears, instead of coming to a point at the out end, were flattened and perfectly covered with very small kernels. I raised the corn for several years, and found it somewhat earlier than the then common corn of the country, which I continued to plant. I never ascertained which yielded the most corn by the acre, but considered there was very little difference. The Dutton corn produced at least a third more corn fodder than the other, and yet after having raised it five or six years, I threw it by, finding it very difficult to prevent its moulding on the cob, by reason of its very great size.

About this time, the farmers generally begun to seek for earlier varieties of corn, and several species were produced; among the rest, a species called Rocky Mountain corn. Where it came from I never ascertained; I raised it for several years. This corn was of a dwarfish growth, but the stalks were rather large in proportion to their height—the cob large and the kernel small—from 12 to 18 rows on an ear, and many of the ears were flat at the end, and covered with small kernels, like the Dutton corn; indeed it perfectly resembled the Dutton in every thing but its size. Is this the Dutton corn of New-York?

A few observations in relation to the crops of spring wheat. You justly remark, in the May number of the Cultivator, page 64, that grain which ripens in cold weather, say late in August or September, will be heavier ordinarily, than that which is hastened to maturity in hot weather. By grain, I presume is meant spring wheat, for I have always considered the earlier oats ripen, the heavier is the grain. From this it might be inferred, that spring wheat should be sowed late, without reference to the grain worm; and yet before the appearance of that insect, it was found by experience, that early sown spring wheat was ordinarily the best. By adverting to certain facts which have been noticed by observing farmers, this may be remedied, and every one may be enabled to render late sown spring wheat a very certain and uniform crop, if not an abundant one. Every attentive observer of the wheat crop knows, that when the wheat grows rapidly with a large straw and a broad leaf, with a peculiar deep green color, having the appearance of that which grows about burnt places, or where the land has been manured for crops instead of the preceding one, the straw will most certainly rust and the grain blast; so that by the time the head appears, it may be ascertained with a considerable degree of certainty, whether the straw will be struck with the rust.

Again—it has been observed by every attentive agriculturist, that grain, whether corn, oats or wheat, put into the ground the last of May or first of June, will be much more luxuriant, and there will be a greater growth of stalks and straw, than when put in the ground early. It follows, as I have found by experience, that so long as we are obliged to sow spring wheat late, to avoid the grain worm, we are much more sure of a crop to sow it not on very rich land, but on a medium soil, which will yield from 15 to 18 bushels to the acre, than to sow it on very rich ground. Since I have pursued this course, my crops have been remarkably uniform, never less than 15 nor over 18 bushels per acre, while others who have sown on very rich ground, have in some seasons had from 20 to 30 bushels per acre, have in other seasons had a great growth of straw, but no wheat.

One other remark in relation to the crop of spring wheat shall close this communication, already much longer than I intended when I sat down to give you the foregoing information relative to the Dutton corn. Since I have sown my spring wheat late, and harvested it in September, it has uniformly made a whiter flour than it did formerly when I sowed it early.—This, however, may be owing to its having been harvested in a greener state than formerly. Wheat ripens so very slowly in September, that we are very sure to cut in a green state. I suspect, however, that when the grain ripens in August, the heat of the sun may darken the colour of the flour.

DAN CHIPMAN.

EXTRACTS.

Science of Gardening—*in continuation.*

ATMOSPHERIC AIR.

All water openly exposed contains more or less of the air of the atmosphere, which consists of two gases, namely, twenty-one parts, by measure, of oxygen, and seventy-nine parts of nitrogen or azote, with, in general, about one thousandth part of carbonic acid gas. It is chiefly owing to the atmospheric air, and a little carbonic acid gas, that common water, though said to be tasteless, is agreeable to drink; for when these are expelled by boiling, it tastes vapid and unpleasant.

That the air contained in the water which enters into plants is important to vegetation, appears from water being found beneficial, in proportion as it has had opportunities of becoming mixed with air. When meadows accordingly are laid under water artificially in the process of irrigation, it is found rather hurtful than beneficial if the water is not kept in motion, but allowed to stagnate.

It is on this account, that the water of rivers which run a long course, is much better for watering than that of springs or lakes, whose waters contain but a small portion of air, though this does not apply so well to the stagnant water of ponds or ditches, whose deficiency as to atmospheric air is compensated by the greater portion of carbonic acid and other substances derived from the decaying animal and vegetable substances usually abundant in such places.

The best water, however, with respect to the quantity of atmospheric air, is rain, which falling in small drops, often tossed about by the wind, has an opportunity of collecting a large proportion of air during its descent to the earth; and hence, the smaller the bore of the holes in the nose of a garden watering-pot the better.

As water becomes mixed with air by exposure and agitation, so does the air become mixed with water by its rising in vapor, and the driest air accordingly always contains more or less water in the state of invisible vapor. The quantity of this vapor is in proportion to the temperature; and hence, the warmer the air the greater proportion of vapor it contains.—A beautiful provision for affording some little refreshment to plants at the very time they are exposed to exhaustion in hot weather, the operation of which we shall afterwards see when we come to consider the use of leaves.

CARBON AND CARBONIC ACID GAS.

Carbon is pure charcoal, which is well known and easily proved to form a large proportion of most vegetable substances,—the oak, for example, contains sixty ounces in a cubic foot; consequently the living plant must have the power of deriving it from carbonic acid gas, for it has been proved by the experiments of Sir H. Davy, that the most finely powdered carbon is not taken up by plants in the solid form.—Nothing, indeed, is more hurtful to plants than smoke, which is carbon mixed with watery vapor; though soot, which is condensed and collected smoke, is useful when spread upon the soil, so that water may derive from it a portion of its gases.

All animal and vegetable substances, in a state of fermentation or putrefaction, give out a considerable portion of carbonic acid gas, and if it is not dissipated by heat, but confined on or beneath the surface of the soil, it will become mixed with the moisture there, and be taken up by the spongelets or the roots of plants. A great quantity of carbonic acid is also produced by the breathing of animals and by burning wood, peat or coal; and being heavier than the air of the atmosphere, it must all descend, in the first instance, to near the surface of the soil, into which much of it must be carried by rains and dews. When it becomes diffused in the air, however, its weight has little influence in causing it to descend.

The carbonic acid gas thus mixed with water, and taken up along with it into the system of plants, is there decomposed, as we shall afterwards see, into its constituent parts of oxygen and carbon, part of the oxygen being given off into the air, and the rest with the carbon remaining in the plant, where it goes to form most of the solid parts as well as the nutrient pulp.

The carbonic acid also exists in soils combined with lime, magnesia, iron, and some other substances in the form of carbonates, which are soluble with great difficulty in very small quantities in water, but readily in humic acid, as we shall immediately see.

NITROGEN OR AZOTE.

This gas, as we have already seen, constitutes by much the largest portion of the atmospheric air, and consequently must enter largely into the system of a plant, though it is not found in general to contribute so much to vegetable as it does to animal substances, in all which azote is in considerable proportion.

Azote is found in larger quantity in cabbages, savoys, cauliflower, brocoli, sea-kale, turnips, radishes, mustard, and cresses, than in any other garden plants, and it is this which in part produces in these the peculiar acrid taste which most of them possess. It is also a chief ingredient in starch and in the gluten of wheat. It is the nitrogen, also, which, escaping from these when boiled, or when in a state of fermentation or decay, is diffused around and produces an odor in general very strong and disagreeable.

It will follow, that as these plants when healthy, contain much nitrogen, it ought, in rearing them, to be abundantly supplied from its two chief sources—the air and decaying animal substances,—in other words, by free air and animal manure. Though when it is an object, as in the rearing of sea-kale, to render the flavor mild, the supply of nitrogen must for the reason be diminished.

HUMIC ACID OR HUMIN.*

This important substance was first discovered by Klaporth in a sort of gum from an elm, but it has since been found by Berzelius in all barks; by M. Braconnot in saw-dust, soot, starch, and sugar; and what is still more interesting for our present purpose, it has been found by Sprengel and M. Polydore Boullay to constitute a leading principle in soils and manures. Humin appears to be formed of carbon and hydrogen, and the humic acid of humin and oxygen,† but the difference between the two requires farther investigation. Pure humic acid is a deep blackish brown, without taste or smell, and water dissolves it with great difficulty and in small quantities; consequently it cannot, when pure, be available as food for plants.

Humic acid, however, which, I may remark, is not sour to the taste, readily combines with many of the substances found in soils and manures, and not only renders them, but itself also, easy to be dissolved in water, which in their separate state could not take place. In this way humic acid will combine with lime, potass, and ammonia, in the form of humates, and the smallest portion of these will render it soluble in water, and fit to be taken up by the spongelets of the root fibres.

It appears to have been from ignorance of the important action of the humic acid, in thus helping to dissolve earthy matters, that the older writers were so puzzled to discover how lime and potass got into plants, and it seems also to be this chiefly which is so vaguely treated of in the older books on gardening, &c. under the names of *extractive vegetable extract*, *mucilaginous matter*, and the like. Saussure, for instance, filled a large vessel with turf, and moistened it thoroughly with pure water; when, by putting 10,000 parts of it by weight under a heavy press, and filtering and evaporating the fluid, he obtained twenty-six parts of what he termed *extract;* from 10,000 parts of well dunged and rich kitchen garden mould, he obtained ten parts of *extract;* and from 10,000 parts of good corn-field mould, he obtained four parts of *extract.*

M. Polydore Boullay found that the liquid manure drained from dung-hills contains a large portion of humic acid, which accounts for its fertilizing properties, so well known in China, and on the continent; and he found it also in peat earth, and in varying proportions in all sorts of turf. It appears probable, from Gay-Lussac having found a similar acid‡ on decomposing the prussic acid,§ that the humic acid may be found in animal blood, and, if so, it will account for its utility as a manure for vines, &c. Dobereiner found the gallic acid convertible into the humic, from which, indeed, it only appears to differ in its water of crystallization.

Young Men's Department.

Hints to Young Farmers—No. VIII.

REMEMBER CONSEQUENCES.

We once read an interesting anecdote of a young man, who went to spend the Christmas holidays among a group of female cousins. Pawn plays having been introduced in an evening party, the young visitor very unexpectedly declined participating in them. On the company retiring, his cousins surrounded him, and insisted on knowing his reason for not joining in the sports of the evening. Why girls, says he, Aunt Elois makes it a rule never to serve cheese cakes to company; for, she says, if she has cheese-cakes she must have custards, and if she has custards she must have pound cake—and he went on to enumerate a dozen superfluities which must all necessarily follow the introduction of cheese-cakes.—Now, cousins, if I play pawns I must kiss, and if I kiss, I must——his further utterance was stopped by half a dozen hands which were pressed upon his mouth.

By way of improvement, we would admonish the young farmer, that his first step in extravagance, beyond what is befitting his business and his means, be it in dress, furniture or equipage, is like serving up cheese-cakes or playing at pawns—the other consequences will follow as certainly as night follows day. Better, by far, take counsel of Aunt Elois,—seek not to entertain company with cheese-cakes, and you may thus reserve to yourselves, for appropriate occasions, both the custards and the kisses.

The natural wants of life are few, and they are most essential to our health and happiness. Our artificial wants are boundless, and the more they are gratified the more they multiply, and the more craving are their demands. He who seeks only to please himself, to study the comfort of his family, and to perform his known duties, depends not, for the enjoyments of life, upon the smiles or favors of others.—But he who, disregarding these, builds his hopes of happiness upon an ostentatious display—upon the applause, mingled as it ever will be with the jealousy and envy, of the multitude, mistakes the true philosophy of life.

While we would caution against extravagance, we are no less opposed to mean parsimony. As men acquire means, they ought to multiply around them the enjoyments of polished—we do not mean by this, fashionable—life. They ought particularly to give to their children those advantages which will fit them not only for usefulness, but for intercourse with the intelligent and respectable classes of society. In truth, the spirit of the age demands, that the children should receive a better education, to qualify them for usefulness, than that which has been bestowed upon the parents.

But in all that may be denominated superfluous expenditures—the man should consult his purse before he consults his wife—or, particularly, his daughters—and, by all means, *remember consequences.*

Maxims for Farmers.

"*Come boys,*" is the best countersign upon the farm. Even if his hands are not employed, the eyes of the master have wonderful efficacy in accelerating labor.

If you would judge of a man's character, look not at his coat, but at his habits. The first may change with the moon,—or what is the same, with the fashion—the latter are generally as abiding as life.—The first may be the property of another—the latter, like the shadow, belongs exclusively to the man.

Men deserve commendation, not for refraining to do evil, for they may not be in temptation—but for the good they do; not for negative, but for positive virtues.

Every industrious man, by his labor, manual or mental, depends upon his personal exertions for fortune and for fame. Every indolent man depends for subsistence upon the labors of others—upon patrimonial resources, upon trick and fraud, or upon—we mean no personal disrespect by the use of this very appropriate term—the "*spoils*" of office. One adds to the common stock of wealth and human enjoyment—the other adds nothing. The last are like the grain-worms, which consume our crops, without rendering any equivalent to society. Yet as nothing is created in vain, the worm may be intended, perhaps, to excite our constant vigilance, and the man as a living example of human folly—and of the perversion of human faculties.

Importance of improving the Mind.

Although knowledge and the improvement of the mind have long been considered least necessary in agriculture of any other occupation, almost, in which men are engaged; there is still good reason to believe that there is no other which can be benefitted by it, to so great an extent. Farmers are now beginning to see the importance of science, and the advantages it affords to agriculture. Almost every operation in tillage depends for its results on the chemical combinations of substance and for the food of plants. No calling in life, hardly, may be so greatly benefitted by a thorough knowledge of chemistry. What manures are best applied to particular soils; what to the growth of particular vegetables; the mode of treatment best adapted to the cultivation of particular plants, depend almost wholly on chemical affinity and chemical combinations.

The farmers' interests depend principally on the operation of natural causes; and science has for its object the investigation of nature; therefore science must be deeply interesting to the farmer. A knowledge of natural physics could be turned to good account every day. A man might not know that he wastes his time and money in trying to make water hotter after it boils, or think that by burning green wood he makes a saving; but the science of heat would learn him better. He might think it anomalous that he could not get water up in his pump higher than 33 feet; but pneumatics and hydrostatics would teach him the reason. He might run to a lightning rod for protection in a thunder storm; but a knowledge of electricity would bid him beware. In short, the advantages which science affords to man in every situation in life, are more than he can enumerate.

But science does not alone affect a man's interest. Man has a mind which it is his duty to cultivate. It is adapted to the study of nature, and was no doubt designed for it by our Creator. It is expanded and ennobled by it. Who can consider the adaptedness of man to his situation—how exactly every thing around him is calculated to promote his happiness, and he to enjoy it—the fitness of the eye to the properties of light, conveying to the mind the most exquisite sense of beauty, together with being so useful that, without it, life is almost a burden; and the wonderful harmony which exists throughout nature, without feeling that his mind is enlarged, and that he is wiser and better for it?

Men ought to possess a spirit of inquiry; or, to use a familiar phrase, to get in the habit of philosophising. It is too common for men who have opportunities for improving by a contrary course, to pass over the works of nature without asking or thinking of the cause of the various phenomena around them. No class of men is so favorably circumstanced to profit by the study of nature as the farmer: and yet, few consider that study of less importance· "It is not leisure that mankind needs, (says Robert Mudin, in his Observation of Nature,) it is stimulus and activity; and study, even the most profound and abstruse study, thrives better in the few snatches of time which the busy man can spare for it, than in all the listless and loitering days of him who has nothing to do." If this be true, we see that the general excuse of want of time, is without validity. We have opportunities for study in our every day labor—in our walks for recreation—in every tree and plant—in every change in the atmosphere—in the clouds above our heads, and in the earth beneath our feet—in short, in every natural object or appearance by which we are surrounded. It is the practice of thinking and investigation—of taking notice of what occurs around us, and trying to ascertain the causes of such phenomena and effects as come under our observation, that the mind is rendered active and stored with really useful knowledge. To observe and think are in the power of every man; it merely requires the activity of the mind while the body is in action. The study of nature and the advantages to be derived from it need cost us but little; no expensive apparatus is requisite; we have only to use our natural senses and our minds to gain the desired end.

Consider a little the results and advantages of such observation and investigation. It was by these, that Copernicus, after thirty years study, ascertained the sublime harmony and simplicity of the revolution of the heavenly bodies. It was by these, that the vast mind of Newton, from seeing an apple fall from the tree, was led to inquire and at length to find out the cause—the same cause which keeps our world and the planets in their orbits, and connects the whole material universe of God. James Ferguson, while a shepherd boy, and entirely unacquainted with the name, even, of the sciences, from his observation of the heavens constructed a celestial globe; and finally became an eminent astronomer. Franklin, by his researches in the science of electricity, was enabled to wield the thunderbolts of heaven; and, by his invention of the lightning rod, the forked lightnings descend harmless by the sides of our dwellings. Fulton and Watt, by their observation and reflection, brought the steam engine to its present perfection. And we may say, confidently, that every acquisition to science, and every invention useful to man, has been made, not accidentally, as a general rule, but by the proper use of his reasoning faculties.

Does it become the dignity of a reasoning mind—one whom God has made to bear his own image—to pass through life ignorant of what is going on around him? Yet this is the case with him who will not take the trouble to think. He may, indeed, see, and hear, and feel, and know the existence of many things. So does an animal. Our minds were given us for use. There can be no harm in trying to find out the reason and cause of things which are constantly occurring before our eyes. We could live, and perhaps get along well enough in the world without knowing that air (for instance) is a material substance—that it is by its pressure that water can be raised in pumps—that by its weight, that of our own bodies are lessened, and clouds are formed which water the earth; smoke and deleterious gases ascend: and were it not a material substance, we could not live. We might not know that the vegetable creation absorbs that portion of the atmosphere which animals throw off, and then purify it, so that without the vegetable creation, other than as a direct means of support, no animal could long exist—that thus these two great divisions of nature are constantly supporting each other: we might be ignorant of these facts, and perhaps, feel no inconvenience from our ignorance. We might be able to look out on the orbs of heaven, and recognize in them nothing but twinkling points—as inconsiderable masses, whose faint glimmerings are of very little importance; and yet our world and sun perform their offices as regular, and we receive as much comfort from them as ever, while innumerable suns and systems of worlds roll in that azure void. But, might we not as well have been formed without the power of studying the works of God, as to neglect entirely the use of that power?—The legitimate use of *all* our faculties is best adapted to promote our happiness; and *happiness*, whatever

---

[*] In most chemical books, the terms *Ulmic Acid* and *Ulmin* are used, from the Latin *Ulmus*, elm; but as its substance occurs in most, if not all plants, the name is bad. I prefer Sprengel's terms, from the Latin *Humus*, soil.

[†] The soluble and insoluble *geine* of Dr. Dana.—*Cond.*

[‡] Technically, *Azumic acid.*

[§] Technically, *Hydrocyanic acid.*

subordinate ends we seek, is the ultimate object of man's pursuit.

The improvement of the mind is too little regarded by almost all; especially by those whose avocations lead them to active bodily labor. It is too common for this class of men to excuse themselves on account of want of time. "They have so much active bodily labor to perform, that they cannot find time for reading and study." Now this might be a very good excuse, if, for the improvement of the mind, it was necessary for a man to confine himself exclusively to books. But this is not the case. I venture to say, that the man who has received his education and ideas of things exclusively, or principally, from books, is neither a wise nor a useful man. It is the practical manual laborer who combines the education of his mind with his labor, who is best calculated to be useful to the world; and consequently we find, that those who, on the page of history stand most conspicuous for their usefulness, were of this class. Let it not be understood here that I would derogate from the use of books. No: if any art with which man is acquainted should be considered truly sacred, it is that of printing—thus canvassing ideas for the transmission of knowledge. I would say to every young man, read much; read all you can, consistently with your higher duties. But it is the idea that unless a man can spend the most of his time in reading, it is useless for him to try to make himself acquainted with the sciences, that I would combat. Every man, even the most busily occupied, can find some time for reading, without sacrificing his business. Every man needs some time for relaxation from bodily labor.—This is the time, if he can find no other, to be spent in reading: and it can be spent in this way most pleasantly, as one at least can testify. What I would particularly enjoin on my fellow young men is, not to think of *studying* only while engaged with a book; but study while at your labor—in the fields—the forest—every where, and at all times. Nature is the great field for the exercise and development of our mental faculties.

Perhaps some might object to the course recommended, on the ground of its not affording encouragement for pecuniary gain. "They think they could make money faster, without all this trouble of thinking of matters of no consequence." It is a fact that many men consider the great principles of the operations of nature—principles on which depends their very existence, as matters of little importance.—Those who manifest a desire to search out these great truths, especially if it cost them any time, are stigmatized with the odious name of idlers. True, our investigation or knowledge of these principles would not change, or continue them; but it is very far from being true that a knowledge of them is of little importance. To prove this, it will not be necessary to show the superiority of man over an animal—all of us know it. But in what does this superiority consist? Is it in the structure of his body? No, for then you merely make him the more perfect machine. What then? It must be in his mind. Well, if in his mind, in what quality or qualities of the mind does it consist? Is it that man is a *money making* animal? No: it is in his power of reasoning—of investigating the works of his Creator; and in his moral affections. It is in his capacity to trace through the varieties of nature the marks of design and benevolence which lead him up to nature's God.

But aside from this, the improvement of the mind has a direct and most important bearing on the *pecuniary* interests of mankind. This proposition is so self evident as hardly to need illustration. The progress of the sciences depend on the improvement of the mind, or on the power of the mind to trace effects to their causes—and *vice versa.* And it is evident that our pecuniary interests are advanced by an advance of science. By the science of astronomy, and the application of the magnetic properties of iron to the mariner's compass, our ships are enabled to put out into the vast ocean, thousands of miles from land, thus forming channels of communication between different nations, and exchanging the commodities of different countries. By the scientific application of steam to machinery, we have our steam-boats and rail-road cars; and an engine capable of performing almost any kind of labor. So in instances without number, science contributes to the necessities and comforts of man.

More than this; the improvement of the mind is a positive duty: one of the highest duties enjoined on man. It is a duty we owe, both to our Creator and to ourselves. We owe it to our Creator; He has given us a perfect law and standard of action, and commands us, under the severest penalties, to observe and obey them; while that obedience is its own reward. It improves the moral faculties of the mind, and therefore tends to render us happy. We owe it to ourselves; because we ought so to act, keeping the great object of our existence in view, as best to attain the end. We are commanded to "prove all things." We are not called on in the word of God, or in the works of nature, to believe any thing which is opposed to reason. We *cannot* do it. It is contrary to the constitution of mind. We may be, however, and are, bound to believe many things which reason cannot explain or account for. Therefore it is necessary to be able to distinguish between what is reasonable and what is unreasonable, in order, as the scriptures express it, to "hold fast that which is good."

Thus I have attempted to show the advantages of science to agriculture—the feasibility to the farmer of the improvement of the mind by the study of nature—the results of that study—the degradation consequent on its neglect:—that the improvement of the mind is a matter of interest, and that it is a duty. The object of writing this brief essay was to impress on the minds of young men, particularly those engaged in agricultural pursuits, the importance of the improvement of the too much neglected mental faculties. It is truly the mind that makes the man. It is in the power of almost every young man to make himself distinguished for usefulness to the world: though the usefulness should be the motive, and not the being distinguished. "Nothing is of any value, except that which costs us labor." The improvement of the mind will require some exertion. We must expect it: for, like every thing else valuable, it is not to be attained for nothing. But the results of this labor will fully compensate all those who undertake it.

Albany, May, 1838. P.

Chemical Catechism—Chapter II.

OF ATMOSPHERIC AIR.

What are the obvious properties of atmospheric air?

Fluidity, elasticity, expansibility and gravity.

What do you mean by the elasticity of the air?

If atmospheric air be compressed into a small compass, it has the property of recovering its former state as soon as the pressure is removed, which is called its elasticity.(*a*)

What is meant by the expansibility of the air?

The expansibility of the air is its property of being rarified by heat, so as to occupy a larger space than it would at a lower temperature.(*b*)

How far does the atmosphere extend?

The atmosphere is several miles high, but it is so very much attenuated at considerable heights, that it cannot be ascertained how far it actually does extend.

What are the various uses of the atmosphere?

The atmosphere is necessary for the support both of animal and vegetable life.(*c*) It is indispensable in all the common processes of combustion; it ministers to several of the pleasures which we derive from our senses;(*d*) it gives buoyancy to the clouds, and enables the feathered creation to transport themselves from one part of the earth to another.

But what is the use of the atmosphere being so extended so far above the surface of the earth?

It is this great extension of the air which occasions it *weight;* and the pressure of such a weight produces many important effects in the economy of nature.(*e*)

What are the effects of the weight of the atmosphere?

It is owing to the weight of the atmosphere that we are enabled to raise water from beneath the surface of the earth by the common pump,(*f*) and to perform many other useful operations.

What other advantages do we derive from this extension of the atmosphere?

If we had little or no atmosphere, we should have no cold water; for the waters on the face of the earth would all evaporate at a very inferior temperature;(*g*) besides, the arterial vessels of all organized beings, would be so constantly distended, that animal and vegetable life would be endangered.

How are waters and other fluids preserved to us by the weight of the atmosphere?

The weight of the atmosphere, pressing on the water, binds it down as it were, and prevents the usual heat of the sun from converting this and all other fluids on the face of the earth into vapor.

How does the weight of the atmosphere operate so as to be beneficial to the animal and vegetable creation?

The uniform pressure of the atmosphere on the *exterior* of all organized beings, counterpoises the *internal* pressure of the circulating fluids, and preserves the vessels in due tone and vigor.(*h*)

What is the weight of the atmosphere?

Each square foot of the the earth's surface sustains about 2,160 pounds of atmospheric air. A column of air an inch square weighs about fifteen pounds.(*i*)

What other advantages do we derive from this immense atmosphere?

The great density of the atmosphere gives a proper temperature to the rays of the sun: it also reflects those rays so as to give a lucid brightness to every part of the heavens, and is the cause of those dews and rains which make the earth fruitful.

What is the real nature of the air which forms the atmosphere of this earth?

This immense atmosphere is composed of oxygen and nitrogen, two different airs, which are intimately mixed in certain definite proportions.

Are oxygen and nitrogen the only substances which enter into the composition of the atmosphere?

No; atmospheric air contains also about one part in every thousand of carbonic acid gas, and several adventitious substances.

What other substances are found in atmospheric air?

Besides carbonic acid gas, it holds a portion of water in solution; and sometimes contains hydrogen and carburetted hydrogen gases.

What are the sources of these other gases?

Carbonic acid gas is constantly formed by the respiration of animals and by combustion: and hydrogen and carburetted hydrogen gases arise from various sources, particularly from marshes, stagnant pools, &c. all which are prejudicial to the animal creation.

If carbonic acid air and carburetted hydrogen air are prejudicial to animal life, how are they corrected in the atmosphere?

These airs, which would cause the death of any animal obliged to breathe them, are the proper nutriment of vegetables, and nature has endowed them with organs for their decomposition.

You have spoken of different gases—what do you mean by gas?

When solid substances are rendered perfectly aeriform by heat, the air thus produced is called a gas, (*j*) to distinguish it from those aeriform substances which return to the solid or fluid state when the heat is removed.

Is there any chemical means of analyzing atmospheric air?

By the operation of different agents, the separate gases may be separated from each other, and the quantity of each ascertained.

Do you know the proportions of the different gases in atmospheric air?

There are about 21 parts of oxygen gas, and 79 of nitrogen gas, in every 100 measures of atmospheric air, or nearly 23¼ of the former and 76¾ of the latter, if the calculation be made by weight.

Is there much difference in the nature of these gases?

The oxygen gas in atmosphere air is the principal supporter of combustion, and the vehicle of heat; and is, as was before mentioned, absolutely necessary for the support of animal life.

What is the nature of oxygen gas, when in a separate state?

Pure oxygen gas has the property of accelerating the circulation of all the animal fluids, and occasions the most rapid combustion of all combustible substances; so that it is the most energetic and powerful agent that we are acquainted with.

What is the specific gravity of oxygen gas?

Oxygen gas is a little heavier than atmospheric air, and about 750 times lighter than water.

What are the principal properties of nitrogen gas?

Nitrogen gas, or azote, is chiefly distinguished by certain *negative* qualities, such as its being incapable of supporting combustion and animal life,(*k*) it is uninflameable, and somewhat lighter than atmospheric air.

Seeing that nitrogen gas is injurious to animal life, what is the use of so large a quantity of it in atmospheric air?

Nitrogen gas has the effect of neutralizing, in some measure, the properties of oxygen gas, and rendering it fit for respiration and combustion.

How is this change effected by nitrogen gas?

By the union of nitrogen gas with oxygen gas: the latter is so diluted and modified as to prevent combustion from being too rapid and respiration too stimulating; and by the due proportions in which these gases constitute the atmosphere, the compound possesses properties so different from either of them as to be admirably fitted for every purpose for which it was designed.

How does atmospheric air support life?

By giving out its oxygen and caloric to the blood.(*l*)

What do you mean by caloric?

Caloric is the name which modern chemists have given to fire, or the matter of heat; a large portion of which is intimately combined with atmospheric air.

Is the caloric which is combined with the air we breathe, sufficient of itself, to keep up the necessary heat of the body?

Animal heat is preserved chiefly by the inspiration of atmospheric air. The lungs which imbibe the oxygen gas from the air, impart it to the blood; and the blood, in its circulation, gives out the caloric to every part of the body.(*m*)

How do clothes conduce to preserve the heat of the body?

As the temperature of the atmosphere in this climate is always inferior to the animal temperature, clothes(*n*) are necessary to prevent the sudden escape of that heat from the surface of the body(*o*) which the lungs have separated from the atmosphere.

What becomes of the nitrogen which was combined with the oxygen in atmospheric air?

The greatest part of the nitrogen is thrown out of the lungs at every respiration; and being somewhat lighter than atmospheric air, it rises into the atmosphere to await fresh combinations.

What provisions has nature made for restoring the vast quantity of oxygen which respiration and combustion are perpetually taking from the atmosphere?

The leaves(p) of trees and other vegetables give out during the day, a large portion of oxygen gas,(q) which, uniting with the nitrogen thrown off by animal respiration, keeps up the equilibrium, and preserves the salubrity of the atmosphere.

Is this perpetual renovation of the atmosphere owing to a fortunate concurrence of circumstances, or is it the effect of design and contrivance?

When we recollect the various processes of nature and of art, which concur with respiration and combustion, in depriving the atmospheric air of its oxygen; and that, notwithstanding the atmosphere uniformly contains every where the same proportion of this gaseous substance, we can attribute the renovation to nothing but design, and perceive in it a proof that the laws of nature must be referred, not to blind chance, but to unerring intelligence combined with infinite goodness.

NOTES.

(a) It is now generally supposed that the air owes its elasticity to *caloric,* and that if it could be entirely deprived of the matter of heat, it would loose its elastic form.

The rebounding of a common foot ball would be a familiar instance to explain the elasticity of the air to a child; also the bubbles of air rising from the bottom of a glass of water, which will be seen to dilate as they rise to the surface, owing to the pressure of the liquor becoming less and less upon them.

The air gun and the forcing pump are constructed on this principle of elasticity. It is by this property of the air that fishes are enabled to rise and sink in the water; nature having furnished them with an *air bladder;* which they have the power of contracting or dilating at pleasure. When a fish compresses this bladder, its whole volume becomes less, and it sinks in the water; when the pressure is removed, the air within the bladder instantly expands, and then it is enabled to rise.

(b) If the neck of a bladder, containing a small quantity of air, be closely tied up and held to the fire, the swelling of the bladder, by the rarifaction of the air within it, will afford an idea of the *expansibility* of the air.

Mr. Robins has calculated that the air which is disengaged in the firing of gun-powder, is rarified by the heat so as to occupy a thousand times the space of the whole of the gunpowder employed.

(c) It has been ascertained by experiment that no other gaseous body with which we are acquainted, can be substituted for atmospheric air. All the known gases have been tried; but they all prove fatal to the animal which is made to breathe them. Even water absorbs air when exposed to the action of the atmosphere, and thence becomes a fit element for the various tribes of creatures who inhabit it.

> "The vital air
> Pervades the swarming *seas* and heaving earths,
> Where teeming nature broods her myriad births;
> Fills the fine lungs of all that *breathe* or bud,
> Warms the new heart, and dyes the gushing blood;
> With life's first spark inspires the organic frame,
> And, as it wastes, renews the subtle flame."—*Darwin.*

It is to the presence of air that water is indebted for its agreeable taste. Boiling deprives it of the greatest part of it; hence the insipidity of boiled water.

(d) In the use of atmospheric air, *man* is the only being who gives to it all the modulations of which it is susceptible. With his voice alone he imitates the hissing, the cries, and the melody of all animals; while he enjoys the gift of speech denied to every other. To the air also he sometimes communicates sensibility: he makes it sigh in the pipe, lament in the flute, threaten in the trumpet, and animate to the tone of his passions even the solid brass, the box-tree and the reed. Sometimes he makes it his slave; he forces it to grind, to bruise, to move for his advantage an endless variety of machines. In a word, he harnesses it to his car, and obliges it to waft him over the stormy billows of the ocean.

(e) The pressure of the atmosphere may be shown by a very simple experiment. Place a card on a wine-glass *filled* with water; then invert the glass, and the water will not escape; the pressure of the atmosphere [upwards] on the outside of the card being sufficient to support the water.

(f) In this operation the atmosphere presses equally upon the whole surface of the water in the well, until the rod of the pump is moved; but, by forcing the rod down, the bucket compresses the air in the lower part of the pump tree, which being elastic, forces its way out of the tree through the valve; so that, when the bucket is again raised, that part of the pump tree under the bucket is devoid of air, and the whole *weight of the atmosphere* pressing upon the body of water in the well, forces up a column of water to supply its place; the next stroke of the pump rod causes another column of water to rise, and so long as the bucket fits the pump tree so as to produce a vacuum, a constant stream of water may be drawn from below. A common syringe will show the action of atmospheric air in pumping.

(g) It is the principle of *evaporation producing cold* that occasions the injury which persons sustain by sitting in wet clothes. It is not the water that hangs *upon* them that produces the mischief, but the sudden loss of a large portion of caloric, which is carried off from the body by the evaporation of this water. If a healthy person were closely covered up with his wet clothes, so that no evaporation could take place, he would probably sustain no injury.

(h) Were it not for the weight of the atmosphere constringing the vessels in animals and vegetables, the elastic fluids contained in the fine vessels, would inevitably burst them, and life become extinct.

Persons who have delicate constitutions need not wonder that they are generally much affected by a change in the atmosphere, when they learn, that often in the course of a few hours, there is an increase or diminution of one hundred weight, and from that to half a ton weight, of atmospheric pressure, on each individual, while the *internal pressure* of the circulating fluids remains the same. Supposing a man's body to contain fifteen square feet of surface, (which is near the truth,) he will sustain a body of air of upwards of fourteen tons weight. But it is necessary to remark, that the air presses upwards, downwards and sideways, in every direction, and that it is owing to this equal pressure that we are not injured by the vast weight of the atmosphere; for the equal pressure on all sides resists as much as it is resisted.

(i) A column of air of the height of the atmosphere, when greatest, is equal to a column of water 35 feet high, or a column of mercury of the same size 30½ inches high. Hence water will not rise in a pump more than 35 feet, nor mercury in a barometer stand higher than 30½ inches. A quart measure of atmospheric air weighs about 17½ grains.

(j) All the gases are compounds of solid matter and caloric. It is caloric which separates the particles, and gives to the whole a gaseous form.

(k) Nitrogen forms a part of all animal substances. It is also the base of ammonia, and of the nitric acid. It appears to be favorable to plants, as they grow and vegetate freely in this gas. It seems to be the substance which nature employs in converting vegetables to animal substances, and to be the grand agent in animalization.

(l) By the rise of the breast bone in man, and the descent of the diaphragm, room is afforded for 42 cubic inches of atmospheric air at every drawing in of the breath. A deeper inspiration will give room for more than twice this quantity.

(m) According to Lavoissier, a man generally consumes 32 ounces troy of oxygen gas in 24 hours; that is, the lungs separate this quantity of oxygen from the air which he respires in that time.

(n) Clothes keep the body warm in consequence of the air which they infold within them; all confined bodies of atmospheric air being non-conductors of heat. It is on this principle that double windows preserve the warmth of apartments at an equable temperature. In like manner, double lids for boilers, are found to be very effectual for preserving the heat of the liquor with a very small portion of fuel.

On this principle it is that light spongy substances, such as furs and down, afford the warmest clothing. Hence it is that the carpet of snow which covers the earth in winter, is spread out by nature with so light a hand, that it might hold an abundance of atmospheric air within its interstices, to preserve the warmth of those innumerable tribes of vegetables which it is destined to protect.

(o) We clothe ourselves with wool, because it is a bad conductor of heat, and retards its escape from the body.—The inhabitants of Russia, clothe themselves in fur, because fur is still a worse conductor of heat than wool. Sheep are natives of a temperate climate; but the bear and the ermine of the coldest. The provident care of the Creator is evidently conspicuous in this appointment, and discovers the same undeviating attention to the comfort of all his creatures; hence the clothing of animals in the torrid zone is hair, in the temperate zones wool, in the frigid thick fur.

(p) The *upper* side of the leaf is the organ of respiration: hence some vegetables (as they give out oxygen only in the day,) close the upper surfaces of their leaves during the night. The multiplicity of the leaves of trees indicates the importance of transpiration to a vegetable.

(q) To show the production of oxygen gas from the leaves of plants, fill a glass bell with water, introduce some fresh leaves under it, and place the bell inverted in a flat dish of water. Expose the apparatus to the rays of the sun, and very pure oxygen gas will be disengaged, which will displace the water in the jar and occupy its place. In like manner, a sprig of mint, corked up with a small portion of carbonic acid air, and placed in the light, will absorb the carbon and render the air again capable of supporting life. The plant purifies what the animal had poisoned.

All the oxygen, however, is not given out by plants; part must be retained to form the sugar and acids which are found in vegetables.

Horticultural Association of the Valley of the Hudson.

☞ A meeting was called for the 30th May, to be held at the rooms of the Lyceum of Natural History, 563 Broadway, N. York, to organize an association, under the style of "The Horticultural Society of the Valley of the Hudson." The objects of the association are to facilitate the introduction into our orchards and gardens, and of disseminating, all the choice kinds of fruits and vegetables which are adapted to our soil and climate, and of improving our taste for the rural embellishments and ornamental gardening—objects highly conducive to the comfort and rational enjoyment of all classes of the community. The circular calling the meeting, bears the names of several highly respectable gentlemen and professional gardeners, and invites the attendance of all who are anxious to promote the objects of the association.

☞ Ruta Baga Seed. ☜

A parcel of genuine *purple top* Ruta Baga Seed has been left at the Cultivator office, in half pound papers, for sale, by a gentleman who imported it direct. Price 75 cents per lb.

*Moneys received during the last month, in sums of five dollars and over. The total receipts are included from post-offices marked with an asterisk.**

FROM THE STEAM PRESS OF
PACKARD & VAN BENTHUYSEN.

THE CULTIVATOR:

A MONTHLY PUBLICATION, DEVOTED TO AGRICULTURE.

I KNOW OF NO PURSUIT IN WHICH MORE REAL AND IMPORTANT SERVICES CAN BE RENDERED TO ANY COUNTRY, THAN BY IMPROVING ITS AGRICULTURE.—*Wash.*

VOL. V. NO. 3, WASHINGTON-ST. ALBANY, N. Y. JULY, 1838. NO. 5.

Conducted by J. BUEL, of Albany.

TERMS.—ONE DOLLAR per annum, to be paid in advance. Subscriptions to commence with a volume.

Special Agents.—L. & R. HILL, Richmond, Va.; BELL & ENTWISLE, Alexandria, D. C.; GIDEON B. SMITH, Baltimore, Md.; JUDAH DOBSON, bookseller, and D. LANDREITH, seedsman, Philadelphia; ISRAEL POST, booksellers, 88 Bowery, ALEX. SMITH, seedsman, P. WAKEMAN, office of the American Institute, Broadway, N. York; E. M. HOVEY, Merchants's Row, Boston; ALEX. WALSH, Lan[illegible] and WM. THORBURN, Albany, gratuitous [illegible] list of agents see No. 12, vol. iv.

The Cultivator is subject to common news[illegible]

☞ Price of the published volumes, 50 cents per vol. stitched—the four volumes bound together, $2.75—bounded in two volumes, $3—the four vols. bound each separate, $3.25.

THE CULTIVATOR.

TO IMPROVE THE SOIL AND THE MIND.

Hints for July.

From a belief of its utility, confirmed by several years' practice, we earnestly recommend a trial, to those who have not adopted the practice, *of curing their clover hay, and such as abounds in clover,* IN GRASS COCKS, instead of spreading and curing it in the old way. It will save labor, save hay, and add much to the value of that which is housed. As soon as the grass has become wilted in the swath, and the external moisture evaporated, and by all means before any of the leaves become dry and crumble, put the grass in grass cocks, as small at the base as possible, not to exceed a yard in diameter, and taper them off, by adding forkfulls, to the apex, which may be four to five feet from the ground. Leave them undisturbed at least 48 hours, and until you are pretty certain of sun or a drying wind; then open the cocks, and if once turned, the curing will be complete in three or four hours, scarcely a leaf will be wasted, and the hay will be bright, fragrant, and will keep well.

Cut small grain before it becomes dead ripe, for the following reasons: 1. If omitted, bad weather may intervene and delay the harvest too long. 2. Dead ripe grain wastes much in harvesting. 3. Early cut grain makes the best flour. 4. When any portion of the culm or straw has ripened, or become dry, there is no further supply of nourishment from the soil; and the grain then gets as much food from the cut as it could get from the standing straw. Hence, when the straw turns yellow under the ear, however green the rest part of it may be, the grain should be cut. And when the straw becomes badly affected with rust or mildew, the sooner it is cut the better.

Do not put the plough into your corn, if you have, as you may have for a trifle, a cultivator or horse-hoe. It severs the roots, which are the mouths of the plants, turns up and wastes the manure, which should always be applied to this crop, and deprives the plants of more than half their pasture. *Hill your corn but slightly.* Hilling renders it more liable to suffer from drought, and induces it to throw out a new set of roots, the old ones being in a manner useless, by being buried too deep, and beyond the reach of the influence of heat and air, the indispensable agents of nutrition and vegetable growth.

Rural Embellishment.

There are few things hetter calculated to attach us to our HOMES,—where the social virtues love to congregate, and to dispense their blessings—than rural embellishments. This is true whether we apply the term to our neighborhood or individual abode.—The public grounds about the great cities of the old continent, some of which comprise an area of five hundred acres, are the theme of general admiration, the theatres of healthful exercise and recreation, and the sources of high intellectual enjoyment. The lesser towns and villages, even of our own country, owe more of their charm and interest to the trees and plants which embellish their squares, streets and grounds, in the eye of a man of taste, than to any ostentatious show of brick and mortar—more to the beauties of nature than to the works of man. Nay, the highest efforts of the human intellect are in vain put in requisition to imitate the handy-works of the Creator. And when we come down to the suburban residence, and even to the unostentatious abode of the farmer, how are their beauties heightened, and their value enhanced, by a screen of ornamental trees, and a well kept garden.

Loudon tells us, that in travelling from Strasburgh to Munich, he passed through a continued avenue of fruit and forest trees, planted on both sides of the highway, for more than one hundred miles. Who that has passed through New-England, in summer, has not admired, in some of the villages, the beautiful trees with which they are in a measure enshrouded. The great objection to planting is, that one may not live to enjoy the fruit or the shade of the trees which he plants. Such an objection is unworthy of [illegible] which [illegible] if it does not, have regard to [illegible] and is, besides, affecting to hold a shorter tenure of life than all of us hope for, and most of us expect.—Twenty years ago, at forty years of age, we commenced the cultivation of what was termed a barren untameable common, not an acre of which had been cultivated, and on which neither a tree nor shrub had ever been planted by the hand of man. We have now growing in our court yard, comprising about half an acre, and in the highway in front of it, fifty species of forest and ornamental trees, many of them forty and fifty feet high, more than fifty speices of ornamental shrubs, not including the rose, besides a vast number of bulbous and herbaceous ornamental and flowering perennial plants—the greatest number of which, in all their variety and hue of foliage, flowers and fruit, may be embraced in a single view from the piazza. Most of our fruits have been raised by us from the seed, or propagated by grafting or budding. Yet we can enumerate more than two hundred kinds, including varieties, which we are now in the habit of gathering annually from trees, vines, &c. of our own planting. We feel grateful to God for these rich and abundant blessings, and for the impulse which prompted our labor. We have adduced our own example, not in a spirit of vaunting, but to convince the young and the middle aged, that there is abundant reason for them to plant, with the hope of enjoying the fruits of their labor. The old *should* plant, as an obligation they owe to society, and for the requital of which they have but a short period allowed them.

Our attention has been particularly drawn to this subject at the present inapposite season, by reading the report and constitution of the Bangor association, termed the Ornamental Tree Society, which has been recently formed, and whose object is the embellishment of their city by planting out forest trees. The constitution requires, that "every member shall himself set out, or cause to be set out, one or more ornamental trees, on such of the public streets or squares of the city as he may elect"—the kind of tree, and distance of planting, to be determined by the directors. Accompanying the report, in the New-England Farmer, are two letters from Gen. Dearborn, on ornamental planting, evincing much experience and good taste in the matter.

The General considers the planting of only one kind of tree as evincing a bad taste.

"The monotony of appearance, which lines, or clumps, of the same tree produce, is to be avoided, and a picturesque and agreeable aspect obtained, by increasing the varieties; for as the periods of their foliation are so very different, as well as the tints of green when in vegetation, and the remarkable autumnal changes quite as dissimilar, they are presenting an ever varying, yet always pleasing and interesting scene. Besides, we have so many magnificent species of native trees, which flourish luxuriantly, even in the most exposed situations, that I have never been able to divine, why one particular tree should be so universally selected, as shades, or for ornament, not only around private dwellings, but for all public places. As well might all flowers be excluded from our gardens, but the rose, or the lilac, and all fruits from our orchards but the apple."

"For your streets I recommend the alternate planting out of rock maples, elms, white ash, white maple, basswood, beech, and red, white and other oaks. [We will add to the list of native trees the button wood, tulip tree, or whitewood, and cucumber tree, (*magnolia accuminata*,) for the city and village, and the black walnut, butternut and honey locust for the country.]—The rock maple is certainly one of our most superb trees, and in my own estimation superior to the elm—Its form and foliage, with the splendid changes of its autumnal aspect, are of surpassing beauty. The basswood, (*Tillia Americana*,) is the American linden, or lime, and much superior, for its size, graceful form, and large leaves, to the much celebrated and favorite European species. It is easy to transplant, and of rapid growth. The oaks are of rapid growth, and one renowned as the name of England, and have been the choice trees of all the celebrated nations of antiquity. The occidental plane, or American buttonwood, is also a finer tree than the oriental variety, which was so much admired and cultivated by the Asiatics and Romans."

For public grounds and squares, the General recommends, also, the white pine, cedar, hemlock, spruce, and we would add the fir, the larch, and a sprinlking of foreign trees, as the English and Scotch elms, lar[illegible] abeel, horse chesnut, mountain ash, &c. w[illegible] be obtained at the nurseries. He recom[illegible] England, that the roots be taken up as entire as possible; that the trees be *not more than two inches in diameter;* that the tops be not cut or mutilated.—"*Do not*," says he, "*cut off a single twig*, save such as may be within four or five feet of the ground."—He also directs that large and deep holes be made for the reception of the trees, and that these holes be filled with the best mould, to be well trod down and watered after the tree is planted. In regard to coniferous and other evergreens, Gen. Dearborn recommends, that they be taken from open grounds—(nurseries are the best,)—all the limbs carefully preserved, and as much of the dirt about the roots retained as possible. "The best time," he continues, "to transplant all the evergreen trees is later than that for the decideous, and is *just before they commence vegation.*" These directions are all good; yet we would amend, or rather add, to the one which regards the *time* for transplanting evergreens. We transplant them *just after vegetation has commenced*—have transplanted in July, with entire success—and our friend Michael Floy, of New-York, a professional nurseryman, prefers the month of August. He showed us the other day, several large firs, which had been planted at that season, in front of his grounds at Harlem, all of which lived and did well. We think evergreens should be planted *when the tree is growing*—as the foliage requires a constant supply of nourishment through the roots; and if the functions of these are dormant, as they are likely to be when evergreens are transplanted when vegetation is at rest, the foliage is apt to wither, and the plant to die: and the only danger to be feared from transplanting these trees at midsummer, is that which arises from excessive evaporation. To guard against this, as much earth should be lifted with the roots as is practicable,—the holes for their reception should be large and deep, filled to the proper height for the roots of the tree with loose mould, and well saturated with water; the surface around the tree should be well mulched with litter, and this well wet, and superficially covered with earth, and the plants occasionally watered if the weather is hot and dry.

As to the effect of planting, *upon the beauty of the landscape*, Mr. A. J. Downing, in a well written article upon this subject, justly remarks—

"Many a dreary and barren prospect may be rendered interesting—many a natural or artificial deformity hidden, and the effects of almost every landscape may be improved, simply by the judicious employment of trees. The most fertile countries would appear but a desert without them, and the most picturesque scenery in every part of the globe has owed to them its highest charm. Added to this, by recent improvements in the art of transplanting, the ornamental planter of the present day may realize, almost immediately, what was formerly the slow and regular production of years."

Mr. Downing is about to publish a work on our forest trees, and ornamental planting, a task for which he is eminently qualified, by good taste, science and practical knowledge.

As to the effect of planting and gardening, *upon the body and mind* of those who engage in these pursuits, we offer the following extracts from Loudon's Suburban Gardener, and we recommend them to the special notice of all gentlemen who are troubled with dyspeptic or hypochondriac affections.

"There is," says our author, "a great deal of enjoyment to be derived, from performing the different operations of gardening, independently of the health resulting from this kind of exercise. To labor for the sake of arriving at a result, and to be successful in attaining it, are, as cause and effect, attended by a certain degree of satisfaction to the mind, however simple or rude the labor may be, and however unimportant the result obtained. To be convinced of this, we have only to imagine ourselves to be employed in any labor from which no result ensues, but that of fatiguing the body, or wearying the mind: the turning of a wheel, for example, that is connected with no machinery; or, if con nected, effects no useful purpose; the carrying a weight from one point to another and back again; or the taking a walk without any object in view, but the negative one of preserving health. Thus it is not only a condition of our nature, that in order to secure health we must labor; but we must also labor in such a way as to produce something useful or agreeable. Now of the different kinds of useful things produced by labor, those things surely which are living beings, and which grow and undergo changes before our eyes, must be more productive of enjoyment than such as are mere brute matter—the kind of labor and other circumstances being the same. Hence, a man who plants a tree, a hedge, or sows a grass-plat in his garden, lays a more certain foundation for enjoyment, than he who builds a wall or lays down a gravel walk; and hence the enjoyment of a citizen, whose recreation, at his suburban residence, consists in working in his garden, must be higher in the scale, than that of him who amuses himself in the plot round his house, with shooting at a mark, or playing at bowles."

A strong illustration of this truth lately came within our knowledge. An esteemed friend, who had become wealthy and retired from active business, at the middle age of life, had become particularly diseased in body and mind. We advised him to recreate himself in horticultural pursuits, as an antidote to both maladies. He replied, that he had no taste, and could not acquire a relish for these pursuits. We thought otherwise; and as he was going to spend the summer with a relative, on a farm which belonged to him, we presented him with half a dozen trees, asked him to plant them on his farm and to report to us in autumn, whether they had afforded him any gratification. When he returned from his summer residence, he confessed with gratitude, that they had been to him a source of high interest and gratification; that they had received his constant care and attention; that the had watched, with a kind of paternal feeling, the development of the leaves, and the growth of the branches; that he had examined them almost daily, sedulously guarded them from injury, and watered them with his hand; and that these cares and labors afforded pleasures without alloy. Had our regretted friend made this experiment two years earlier, he would, in all probability, have been now numbered among the living, and probably among the hale and hearty.

But to return to our quotations from Mr. Loudon—"One of the greatest of all the sources of enjoyment resulting from the possession of a garden," remarks our author, "is the endless variety which it produces, either by the perpetual progress of vegetation which is going forward in it to maturity, dormancy or decay, or by the almost innumerable kinds of plants which may be raised in even the smallest garden. Even the same trees, grown in the same garden, are undergoing perpetual changes throughout the year; and trees change also in every succeeding year relatively to that which is past; because they become larger and larger as they advance in age, and acquire more and more their characteristic and mature form." "Independently of the variety of change resulting from the variety of plants cultivated, every month throughout the year has its particular operations and its products: nay, it would not be too much to say, that during six months of the year, a change takes place, and is perceptible in the plants of a garden, every day; and every day has in consequence its operations and its products."

In conclusion: A bountiful Providence has given the vegetable kingdom for our sustenance, employment and highest intellectual enjoyment,—and has scattered these elements of happiness, with a profuse hand, every where within our reach. It is left with us to enjoy them in a greater or less degree, as we learn to appreciate their value, and exert ourselves to apply them to their proper use. The brute is content to satisfy its animal wants. Man, the lord of the creation, should have a higher aim—because he has higher sources of enjoyment than the brute, and higher duties to perform—he is the husbandman appointed to take care of and nurture the great vineyard, and to carry out the wise purposes of the all-bountiful Giver.

We intend, ere long, to name and describe some of the ornamental shrubbery, and perhaps perennial plants, best adapted for the embellishment of court yards and gardens. In the mean time we advise the young to cultivate a taste for rural embellishment, as a preventive of bad habits, and as the source of substantial and innocent pleasure.

Liquid Manures.

All urine, says Davy, contains the essential elements of vegetables in a state of solution, that is, in a condition immediately to become the food of plants. The Flemings and Chinese save and apply all this fertilizing material, either mixed with earths or dung, or in a liquid form, diluting it first with water. Three hundred acres are kept in a condition of great fertility by the liquids which flow from a part of the drains of the city of Edinburgh. The meadows thus fertilized, says Mr. Oliver, let for £24 to £30 per imperial acre per annum, equal to $106 to $136! and in one case, in 1826, the Earl of Moray's meadow fetched £57 an acre!! Some of these lands were, till lately, absolutely barren—sea-sand—and yielding nothing. Thirty acres were levelled and prepared to be irrigated by the liquid filth of the town, in 1821. They now let for £15 to £20 per acre, and are considered susceptible of much higher improvement.—The great value of liquid manure is particularly illustrated in the following quotation which we make from the veteran in horticulture, Mr. Knight.

"I have shown in a former communication," says this distinguished physiologist, "that a seedling plum stalk, growing in a small pot, attained the height of nine feet seven in a single season; which is, I believe, a much greater height than any seedling of that tree was ever known to attain in the open soil. But the quantity of earth, which a small pot contains, soon becomes exhausted relatively to one kind of plant, though it may still be fertile relatively to others; and the size of the pot cannot be changed sufficiently often to remedy this loss of fertility; and if it were ever so frequently changed, the mass of mould, which each emission of young roots would enclose, must remain the same. Manure, therefore, can probably be most beneficially given in a purely liquid state; and the quantity which trees growing in pots have thus taken, under my care, without any injury, and with the greatest good effect, has much exceeded every expectation I had formed.

"I have for some years appropriated a forcing house at Downton, to the purposes of experiment solely upon fruit-trees, which, as I have frequent occasion to change the subjects on which I have to operate, are confined in pots. These at first were supplied with water, in which about one-tenth by measure of the dung of pigeons or domestic poultry had been infused; and the quantity of these substances, generally the latter, was increased from one-tenth to one-fourth. The water, after standing forty-eight hours, acquired a colour considerably deeper than that of porter, and in this state it was drawn off clear, and employed to feed trees of the vine, the mulberry, the peach, and other plants; a second quantity of water was then applied, and afterwards used in the same manner, when the manure was changed, and the same process repeated.

"The vine and the mulberry tree being very gross feeders, were not likely to be soon injured by this treatment; but I expected the peach tree, which is often greatly injured by an excess of manure in a solid state, to give early indications of being over fed. Contrary, however, to my expectations, the peach tree maintained, at the end of two years, the most healthy and luxuriant growth imaginable, and produced fruit in the last season in greater perfection than I had ever previously been able to obtain from it. Some seedling plants had then acquired, at eighteen months old, though the whole of their roots had then been confined to half a square foot of mould, more than eleven feet in height, with numerous branches, and have afforded a most abundant and vigorous blossom in the present spring, which has set remarkably well; and those trees which had been most abundantly supplied with manure, have displayed the greatest degree of health and luxuriance. A single orange tree was subjected to the same mode of treatment, and grew with equal comparative vigor, and appeared to be as much benefitted by abundance of food, as even the vine and the mulberry tree."

To introduce a comparison between the animal and vegetable, we may compare the roots of the latter to the locomotive power of the former, which enables both to *go abroad for food*—constantly to seek new pasture; and the liquid food of the plant to the chyle in the animal stomach—fitted to nourish and become an integral part of the living organic structure. So that liquid food is more readily converted into vegetable matter, than forage and grain is into the flesh of the animal. And the continued extension of the roots is superseded by giving to the plant this cooked food, in the same way that the locomotive power of the ox is superseded by feeding him constantly at the stall.

The above facts may be rendered profitable to the professional gardener, as they suggest a source of immediate fertility always at his command. They will not fail to indicate to the fair, who mourn at the declining beauty of their parlor plants, a ready means of renovating and imparting to them new vigor. The farmer who has hitherto disregarded his liquid manures, and who has suffered to go to waste, the highly fertilizing matters of his dove-cote and poultry-house, will see, at once, from the preceding statement, that he has lost a treasure to his land from his neglect; and if he is not unchangeably wedded to his old habits, he will at once set about availing himself of these valuable sources of fertility.

A weak solution of soda, (one pound in fourteen gallons,) produces upon soils, (says the Sussex Agricultural Express,) the most admirable fertilizing effects.

Mr. Coleman's Agricultural Report.

We regret that our limits do not permit us to extract liberally from this excellent report; but we are obliged to be content with a brief notice of its principal points. We cannot withhold our admiration of a people who by industry and perseverance, have maintained a high reputation as agriculturists, educated large families, and surrounded themselves with the substantial comforts of life, upon a rocky primitive soil, "no part of which can be advantageously cultivated without manure." The farmers of Essex are richly entitled to this commendation; and yet we consider their husbandry defective in many points, and capable, with their habits of application and close observation, of being doubled or trebled in product. But we resume the thread of the report. The next subject in order, is

Fruit Trees—which are cultivated to a considerable extent, and are a source of profit. The trees of one of their best apples, the Baldwin, were principally destroyed by the severe winter of 1833–4; yet in ordinary years the farmer markets 300 barrels of dessert apples. They are hand-picked, packed in dry barrels, placed in a cool cellar, and not generally sold till May. Eight hundred dollars a year, says the commissioner, is not an unusual product of his orchard. These facts present a strong inducement for the cultivation of orchards; and if we superadd the consideration, that apples are now made to constitute a valuable food for all kinds of farm stock, the orchard cannot fail to be regarded as a source of great and certain profit to the farmer. The commissioner notices a new mode of keeping the apple trees free from the canker worm, which until lately has much annoyed them. It is to surround the collar of the tree, or that part which is at the surface of the ground, with a belt of adhesive clay, and then to cover this with tar—the application of tar directly to the trunk of the tree having been found to be injurious.

We cannot pass over the subject of fruit, without paying a merited compliment to one of the inhabitants of Essex, who has distinguished himself as a pomologist—Robert Manning, Esq. of Salem. Mr. Manning has been indefatigable for years, in collecting the best fruits from European and American nurseries, in cultivating, comparing and testing their relative qualities; and he has just published the result of his labors in a work upon fruits, which is highly spoken of, though we have not yet met with it. A choice selection of orchard and garden fruits, adapted to our climates, is a desideratum with all who know how to appreciate the relative value of those kinds which are intrinsically good.

"A taste for flowers,"—we resume our quotations from the report—"and the external rural embellishments of the houses and grounds, is every where springing up. Besides its strong tendency to multiply the attachments to home, among the best safeguards of virtue, and furnishing sources of delightful recreation, it is highly conducive to intellectual and moral improvement."

To preserve plum trees from being destroyed by what is termed the black canker, Mr. C. mentions the successful mode adopted by the Rev. Mr. Perry, and which we have practised for twenty years. It is to cut off all the affected parts, and immediately to consign them to the fire.

Forest Trees.—The commissioner very properly directs the attention of the farmer, to this subject, and cites several cases to show that the growth of forest trees is a profitable appropriation of land—in one case, an acre yielding 60 cords of wood, the growth of 25 years—worth, on delivery, $5 per cord, or $300 for the 25 years—being $12 per acre per ann. Planting forest trees has but commenced in Essex. Among the trees named as springing up, we presume spontaneously, are the white and yellow pine, white birch, &c. Among the cultivated trees, the locust, Scotch fir, and oak are named, and we venture to recommend the white ash and soft maple—the former for dry, and the latter for moist soils, in addition.—The seeds may be readily gathered in quantities at proper seasons; they vegetate freely; their growth is rapid, and they are excellent for firewood and timber, far superior to the white birch.

Fences are principally of stone. The commissioner suggests, that to prevent their being thrown by frosts, as they are apt to be when laid in a trench, that gutters be made on each side of the wall, at a short distance from it, by which all the surface water which would otherwise settle under it, should be immediately conveyed away.

The *Farm Buildings* are generally of wood. The commissioner recommends stone for buildings, with which the country abounds. The approved mode of constructing barns on the slope of a hill, giving the basement for manure and vegetables, and the second story for hay, grain and cattle, is beginning to be followed. Much benefit is supposed to result to the manure by keeping it from the weather.

Slaughter-house offal, is bought by the managers of the poor-house, at 32 cents for every beef killed, and so husbanded as to be rendered profitable to the establishment. The meat from the head is consumed by the inmates; the heads are then boiled for the extraction of the tallow, and thrown to swine; and after being thoroughly picked, they are sold for animal carbon; the jaw and leg bones are sold to the button maker, the claws of the hoof to the comb maker, the skins from the legs to the glue maker; and from the feet is extracted oil. Hogs are fattened, and manure made in the bargain.

Extensive beds of *peat* exist in Essex; much is used for fuel, and sells ordinarily at $8 per cord. A stratum of two feet in thickness, gives 480 cords to the acre.

Great *improvements* have been made and are making, in dykeing salt marsh, and reclaiming fresh water swamps. The prevailing opinion seems to be in favor of draining, though some are content with mere ditching salt marshes. By the former, the product in hay has been threbled. Breaking up of the old sod is considered injurious; yet grass seeds are sown upon it, and stable manure is sometimes applied with advantage. The swamps are reclaimed first by draining, and then by carting on gravel or sand, and sometimes stable or other dung, mixing these with the muck, and sowing oats and grass seeds. Some of these reclaimed swamps are now considered worth $100 per acre. So far as we can perceive, the excellent plan of under-draining has not yet been introduced—the drains being a main one in the centre, and lateral ones running from it to the borders of the swamp. We think this latter branch of Essex farming is capable of being greatly improved by a better system of draining, and by applying the vegetable matter of the swamps as a fertilizing material to the uplands. An extraordinary instance of improvement is noted upon Cape Ann. A district of 584 acres, which forty years ago exhibited only swamps, "frowning hills of granite, and rolling boulders," which was not capable of keeping a cow, without procuring hay for her support, from a distance of several miles, has been reclaimed, improved, and made to produce as follows:

Hay,....................	854	tons.
Indian corn, ...	690	bushels.
Rye,....................	390	do
Oats,..................	130	do
Potatoes, ...	8,635	do

The mowing land is valued at $300 per acre, because, says the commissioner, it will pay a handsome profit upon that price.

We must close our notice of this excellent report, without adverting to many facts which we should be glad to promulgate. Yet before we dismiss it, we must remonstrate against a custom which has obtained "down east," and which the commissioner has endorsed by adopting in his report—of attaching the significant term *English*, to products which are no more English, in any sense, than they are American or French. Thus they speak of *English* meadow, comprising grasses that are indigenous to the United States; of *English* grain and *English* turnips; of *English* cherries, and of *English* strawberries, which came originally from our continent. The distinctive term, thus applied, may be very well understood *at home*, though we confess, Yankee as we be, we are often much puzzled to *guess* at precisely what it means. The application of it is not, however, conformable to the language of science, or to the spirit of an improving age, and we think it should be discarded at least by those who write for a nation and for posterity.

The Philosophy of Deep Ploughing.

Our best farmers concur in opinion, as the result of their experience, that most soils are improved by ploughing them *deep* during a course of crops, or once in four or five years. We propose to state some of the reasons which present in favor of this practice. And

First. Occasional deep ploughing brings to the surface the fine vegetable matters of the soil, which we all know, constitute its fertility, or the food of our farm crops, and which, by the operations of tillage, and the force of rains, have sunk upon or into the subsoil. These matters, while deeply buried, are inert, and afford no support to our crops; but brought within the influence of the sun and atmosphere, and within reach of the roots of our crops, by deep ploughing, or the subsoil plough, they are rendered soluble, and made to exert their potent energy upon vegetation—they are fitted for the absorbent vessels of plants, and to become integral parts of them.

In the second place, a deep tilth enlarges the pasture of plants—it permits the roots to roam more freely and extensively in search of food—it permits the surplus water to escape*—and it counteracts the influence of drought. A superficial tilth is much sooner exhausted of its moisture, by the influence of the sun, than a deep one.

And in the third place, its benefits are manifest by the increased product which it gives—these being proportioned, in a measure, to the depth of tilth, when this depth does not exceed ten or twelve inches. See our quotation from Von Thaer, in the second number of our current volume.

Science has furnished other reasons for the practice of occasionally ploughing deep, or rather explained to us the causes of results which were before palpable. Vegetable matters are only available as the food of plants in a soluble state, that is, when they are capable of being dissolved by the liquids of the soil. When deeply buried, these matters are often not soluble; but if brought within the influence of the air, and heat, they soon become soluble, are carried by the liquids in which they are dissolved into the absorbent vessels, and assimilate with the plant. "Soluble geine," that is, decomposed organic, or animal and vegetable matter, says Dr. Dana, "is the food of plants. Insoluble geine becomes food by air and moisture. Hence the reason and result of tillage." Earths, taken from depths so far below the surface as to exclude the agency of heat and air, often abound in insoluble geine, and indeed in the seeds of plants, have, when submitted to a temporary exposure upon the surface, developed uncommon fertility, and seeds have been found to grow. The subsoil plough, which opens to atmospheric and solar influence the long hidden treasures of the earth—its insoluble geine—is a new and important implement for developing the bounties of Providence. It is perhaps preferable to trenching with the spade or plough, inasmuch as the lower stratum is not blended with the upper one, until the air and moisture have imparted to it fertilizing properties—until they have converted its insoluble, into soluble geine. There is reason to believe, that in the great secondary formation of the west, the earth, to a great depth, filled as it is with organic remains, would be found to be fertile upon its exposure to the atmosphere.

These principles, which we have endeavored to explain, serve also to illustrate the advantages of alternating tillage with grass crops—of occasionally opening with the plough, to atmospheric and solar influence, the inert vegetable matters—the insoluble geine—of dividing, pulverizing and mixing the soil, thereby giving a free range to the roots, and counteracting the influence of drought.

We all know, that land will wear out under a constant system of cropping, unless more highly and constantly manured than is consistent with farm economy. It is equally apparent that most meadows require to be top-dressed at least once in three years, to prevent deterioration. Well managed young meadows should give at least three tons of hay to the acre; yet after the second or third year they will deteriorate, if not top-dressed, until they yield but one or two tons the acre. Besides, if manure is applied, as it ought to be, in an unfermented state, and to an autumn-ripening corn or root crop, it will yield twice the benefit to a farm, that it will if spread upon the surface of the soil.

The considerations which we have suggested go to show the propriety of occasionally ploughing *deep* in tillage husbandry, and of alternating grain, grass and root crops wherever the nature of the soil and surface will admit the plough.

Vitality of Seeds.

The following remarkable fact, showing the long retention of vitality in seeds when lying upon the ground, has been related to us by Judge Stilwell, of St. Lawrence, as having taken place in his immediate neighborhood and under his own personal observation. Twenty-one years ago, a neighbor cleared and burnt a piece of ground, and harrowed in grass seeds and turnips. The ground lay 12 years in meadow, and 8 years in pasture, when the plough was put into it for the first time, preparatory for a tillage crop. It was soon discovered, after the soil had been turned over, that it promised a crop of turnips, which must have come from seed grown upon the ground nineteen years before, many of the roots having been then left in the ground over winter, and suffered to seed. A part of the plants were left to grow, and came to high perfection.

Theory and Practice.

Mr. Stevenson, the able conductor of the Franklin Ky. Farmer, has commented, at some length, upon our article in the April Cultivator, "*The new lands of Kentucky wearing out;*" and we are very happy to perceive, that in the main, there are no essential points of difference in our opinions. We made the quotation from his paper, not so much to give the character of Kentucky farming, much of which, we are aware, is excellent, but to show that, under bad management—under *common* management—the best lands will soon become poor; and while we concede all the advantages which he claims from science, we must persist in the opinion, that neither the mere theorist, nor the mere practitioner, are so likely to succeed, in profitable husbandry, as the man who possesses both a theoretical and practical knowledge of the business. We have no schools that combine the two requisites; and hence we suggested the propriety of practical farmers instructing themselves in the science.

Account Current.

Thrifty farmers are in the habit of making out a balance sheet for each year, in order to ascertain what they have made or lost by their farming operations, and with a view to profit from their errors.—Now Uncle Sam is at least nominally a farmer, and, like all other farmers, can only expect to prosper in proportion as his sales exceed his purchases; and, at all events, if we find that he has not raised his own provisions, we may set it down as certain, that he does not work it right, and that unless he mends his ways, he must ultimately fail. The business of this nation, to be independent and prosperous, should be to provide breadstuffs, not only for its own population, but a surplus, sufficient to pay for the foreign commodities which we consume. Such would be the course of the prudent farmer; and we should think little of the shoemaker, or the hatter, who should be obliged to buy shoes or hats for his family.

In striking the balance of Uncle Sam's account, we would premise, that our estimates embrace only breadstuffs, the great staples of the northern and middle states, and which constitute the principal means, in these states, of paying for the foreign merchandize which we consume.

By a statement from the treasury department, it appears, that the importations and exportations of grain, flour and meal, during the year 1837, were as under stated, estimated in dollars.

Articles.	*Imported.*	*Exported.*
Flour,..................	$122,691	$2,987,269
Wheat, ...	4,154,325	27,206
Rye and rye meal, ...	333,695	165,467
Corn and meal,..........	3,918	911,634
Other grain. bread, &c. ..	8,837	325,077
	$4,623,466	$3,416,653
Deduct exports, ...	3,416,653	
Bal. against Uncle Sam,..	$1,206,813	

in the commodities which it is his business to raise and sell, and which he never ought to be obliged to buy.

If we add to this balance of............	$1,206,813
the amount which the old gentleman paid last year for foreign silks, viz.........	14,352,823
and for foreign sugar,.................	12,514,504
It will show an annual balance against him, of............................	28,074,140

Twenty-eight millions of dollars, in articles which it is either his professed business to raise, or which he can produce by his own labor, and from his own soil. This balance would however be reduced by the value of the silk and sugar which he exported in 1837, to about twenty millions of dollars. If these facts were applied to the affairs of an individual farmer, we should naturally suppose that his boys were either too proud or to lazy to work, and perhaps both. And wherein does the analogy fail between an individual farmer and a nation of farmers. A diminution of crops was among the causes of the late national embarrassments; and our surplus products have been relied upon to pay the foreign balances against us.

What would be the conduct of the individual farmer who should find his affairs thus going to ruin? Would he not instruct his boys in the science and practice of his business, and stimulate them to labor, by rewards, that the farm might produce enough and to spare, to pay off his debts, and keep something on hand for a wet day? And if such would be the politic course in the manager of a farm, why would it not be wise in the managers of a state, or of a nation? They give millions annually to aid those who add nothing to our national wealth, and which tend to elevate the idler above the man of industry? Why not give for instructing the farmer and mechanic how to double the profits of their labor? We insist, that the higher branches of learning, when blended with practical instruction in the useful arts, and particularly in the business of agriculture, are more profitable to a state, than they are when applied to the learned professions.

Advantages of Draining.

Make your lands dry, if not the first, is the second precept in good farming. We have many thousands of acres of swamp lands, scattered over our country, which are rich in the elements of fertility, and which would yield them readily to our use, if freed from their surplus water. We have other vast tracts, which have been subjected to the control of the plough, but which make a scanty and precarious return, by reason of their level surface, and the water which settles and remains upon their impervious subsoil. Most of these lands are susceptible of a high state of improvement and of profitable culture, by the simple process of draining, a branch of farm economy which has been neither much practised nor duly appreciated in this, nor, till recently, in those countries of Europe from whence we derive our best lessons in farming. Indeed we think it is but imperfectly, or partially, yet practised in England; and we should rather refer to Scotch husbandry for the best examples in this branch of improvement.

---

* Of this, we have the best proof: one piece of our land, when we began to improve it, was, in wet times, covered with water, which remained there often days and weeks. Since it has been tilled deep, the water never stands an hour upon the surface, except the soil is frozen.

We are aware, that many think, as we did when we *commenced* draining, that they understand all about it, and that they practise it on the most approved, or at least most economical system. But they may learn, as we have learnt by experience, that draining is only economically done when it is *well* done—when the lands are laid dry, and the drains so constructed as to be rendered efficient and permanent. In swamps, the source of the evil,—the fountain of living waters, which flow into the morass, must be sought out, and the waters conducted off before they enter the swamp, or before they approach its surface. On level tenacious soils, or soils reposing on an impervious subsoil, where the rain and snow water settles and stagnates, and where its existence, is generally indicated by the growth of coarse grass, or marsh plants, *furrow* draining must be resorted to, that is, parallel drains must be opened, in a moderately inclined direction across the field, to receive these waters as they settle down, and to free the soil from their incumbrance.

We have published our own opinion, and the opinions of others, repeatedly, as to the best manner of constructing drains—of the materials which are most suitable for making them, and of the situations where under drains are preferable to open ones. The expense of thorough draining seems formidable; but yet, if it is compared with the enhanced value of the land operated upon, and its vastly increased products, it will be seen that the outlay is better than capital at compound interest. If the outlay in draining will nett a return of only seven per cent in the increase of product, it should be gone into; but in almost every case where the operations are judiciously and thoroughly performed, the return in the increased value and products of the land, is generally twice or thrice this sum, and often fifty and a hundred per cent.

We present below a statement of the mode and advantages of improving a wet meadow, in a communication addressed to the trustees of the Essex agricultural society. The writer stated to the trustees, that the whole cost of the land and improvements, up to the time of taking off the first crop, did not exceed $26 per acre; and yet a part of it afterwards produced, in one year, the sum of $100.50 per acre. The communication which we insert below, is accompanied, in the New-England Farmer, by one from Moses French, giving his mode of reclaiming six or seven acres of swamp land, covered with "bushes, flags and rushes," for which he paid $70, and for which he refused $200 after he had made his improvement. But to the statement.

" *To the Trustees of the Agricultural Society of the county of Essex.*

"Gentlemen—In my farm in Lynn, I have a meadow of 70 acres, which eight years ago bore nothing but meadow hay, and produced about one ton to the acre, of a poor quality. The meadow was mostly filled with hassocs. I cut a ditch of eight feet wide and four feet deep, through the centre of the meadow, and many other smaller ditches to drain the water into the large ditch. The length of all the ditches is about four miles. The whole meadow is covered by a soft black mould, from six to nine inches, and then a greyish substance, I call peat, from nine to fifteen inches deep, upon a pan of clay and sand.

"Eight years ago the last fall, I ploughed seven acres of this meadow, and in the following spring I sowed three acres with oats, three and a half to four bushels, half a bushel and one peck red top and one pound clover seed to the acre. In the summer following, I harvested fifty bushels of oats to the acre. In the winter following, when the ground was frozen, I carried on ten cords of compost manure to the acre. This compost contained two cords of night manure, four cords of yellow loam, and four cords of gravel, and was spread evenly over the ground in the spring, as soon as the frost was out. The following summer I cut on an average, three tons to the acre, of good, merchantable English hay. The following year the seven acres produced two and a half tons to the acre, and the third year two tons to the acre. The winter after the third cutting, I top dressed the same land with the like compost, ten cords to the acre. The next year the grass was equally good as the first year's mowing, but decreased in quantity the two following years, in the same ratio as at the first manuring.

Two years after my experiment upon the seven acres, I went over about three acres of the same meadow, while frozen, and cut off all the hassocs, so as to leave the ground smooth, and hauled off the hassocs. In the winter I carried on to the land, ten cords to the acre, of manure from the slaughter house yard, where I kept eight or ten hogs. Early in the spring, this manure was well spread upon the land, and I then sowed to the acre the like kind and the same quantity of grass seed as I did on the seven acres. The following summer I mowed the three acres twice. On one acre which I measured, and about as good as any of the three, I cut the first time three tons of hay, which I sold at $25 the ton, the second cutting one and a half ton, which sold at $17. The whole quantity of hay upon one acre that year, amounted to $100.50. The second year I had an equally good crop on this land as the first, but I did not cut the second crop. The third year the crop decreased, as the crop of the third year upon the seven acres. The winter after the third summer I carried upon this land ten cords to the acre of the like compost as upon the seven acres. The next summer the crop was equally good as the first crop upon the seven acres, but decreased the two following years, and kept pace with the seven acres. I am well satisfied that my meadow should be manured, as I have done, and with like quantity of manure, every winter after the third cutting or third summer, and by this management my meadow will continue to produce good crops of grass without any other cultivation, except keeping the ditches well cleared out. I consider this experiment upon the three acres the best, considering the amount of labor; and should have continued it upon the remaining portion of my meadow, had the surface been smooth and even, but it was very rough and uneven, so that I was compelled to plough it.

"In the exact manner I treated the acres, the three excepted, I have my whole meadow of 70 acres in good grass cultivation, all but fifteen acres, which I ploughed last fall in order for sowing in the spring. My crops of oats and grass have been uniformly good as upon the seven acres. The last summer my oats were sown late, and I cut them for fodder.

"I am, gentlemen, with due respect, your humble servant, ORIN DALRYMPLE."

We beg the reader to remark, that although the lands drained were covered with "a fine black mould, six to nine inches deep," it required a top-dressing once in three years, to maintain its productiveness in grass; and that under this treatment it yielded an enormous profit, in one case exceeding $100 per annum on an acre. We here have a demonstration of the exhausting effects of constantly mowing the same field—of annually carrying off the crop of grass, and returning nothing to the field to maintain its fertility—and we have a strong argument in favor of the alternating system, wherever it can be introduced. Old meadows will not yield more than half a crop, unless they are triennially top-dressed with dung or compost, as practised by Mr. Dalrymple; and to do this, in ordinary cases, is wasting manure. The manure will do twice as much good if it is buried in the soil, in an unfermented state, and first used as food for a hoed crop; and the operations of tillage divide and loosen the soil, and render it more permeable to air, heat, dew, and the roots of the grasses. Those who must, or will have permanent meadows, should follow the example of Mr. Dalrymple, top dress them once in three years, if they would reap the full profits of their labor.

The above will serve to show the advantages arising from draining and reclaiming swamp land, as practised by a Yankee Dalrymple. And it is a singular coincidence, that the evidence of the expense and profits of furrow draining, which first presented for illustrating this subject, is from a Scotch farmer of the name of Dalrymple. We copy in his own words from the Edinburgh Quarterly Journal of Agriculture.

"I am clearly of your opinion," says Mr. Dalrymple, "that well authenticated facts on economical draining, accompanied with details of the expenses, value of succeeding crops, and of the land before and after draining, will be the means of stimulating both landlords and tenants to pursue the most important, judicious and *remunerating* of all land improvements. The statements below will prove the advantages of furrow-draining; and as to the *profits* to be derived from it, they are *great*, and a farmer has only to drain a five acre field to have occular proof upon the point.

"1832, No. 1, Easter, Ladywell and Whinny fields, containing 54 acres, cost £303.17s. for draining; average say £5.12 per acre. These fields were *not* furrow-drained, but cross-drained, and are *not dry enough.* The wheat sold for £11 an acre in the Easter field, the turnips in the Ladywell field at £20.13.4. The drains were all built and covered with small stones, which were obtained quite at hand. The land was formerly completely covered with rushes. Soil stiff (provincial *chattery*) clay, and used to let in pasture at 20s. an acre. Last summer, 1836, the Easter field fed five Cheviot ewes and lambs to the acre.

"1833, No. 2. Horseless and Jennyside fields, 16 acres, cost for draining £98.7s; say average £5.9s per acre. These fields were furrow-drained, 18 feet between each drain, 30 inches in depth, cut with the common and narrow spades, and filled 18 inches with slag, (scoriae,) from an iron furnace contiguous. All the mouths of the furrow drains terminated in main drains, 36 inches in depth, laid with tiles and soles. The fields are *now perfectly dry.* There was a very fine crop of wheat, about 8 acres, which sold for more than £13 an acre. The potatoes brought 15 guineas, and the turnips £21. The land was formerly occupied with whins and rushes, and let for 12s. an acre. When let for pasture I expect to get 50s. an acre for the land. [An increase in value of more than four hundred per cent, and of rent more than sufficient to pay the heavy expense of draining in three years.]

"1836, No. 3. Longbog, nine acres. Cost for draining £69, say average £7.13s. per acre. This field was furrow-drained 16 feet between each drain, 30 inches deep, and cut as in No. 2. The field *is dry*, and bore a good crop of oats. The land was previously drowned with water, and covered with rushes, and brought about 25s. an acre for grazing. A large portion of this field was very stiff clay; but now (Feb. 1837,) that it has been twice ploughed, the soil is quite changed, both in substance and color. The reason why this field cost so much more for draining than No. 2, was, that it was drained in very wet weather, when the land became so poached with carting, that I was nearly beaten with it."

We now transfer, from the work just quoted, the testimony of Mr. Howden, another Scotch farmer, in favor of the great advantages of furrow-draining.

"I have practised the system of furrow-draining," says Mr. Howden, "to a considerable extent, and am fully satisfied that it is one of the greatest improvements ever introduced into our agriculture. It is not easy to say, with certainty, as to the exact increase of produce which may be derived from it, so much depending on the nature of the soil and seasons. The farm which I at present occupy, consists mostly of a clay soil, resting in general upon a retentive sub-soil, and, consequently, was much injured from the retention of rain-water, and, in some places, from water springing from below. The method I am adopting for laying it dry, is, where the subsoil is very retentive, to put a two feet drain into each furrow [dividing the ridges] the breadth of the ridges being 18 feet. Where the subsoil has a tendency to draw under-water, I lay two such ridges together, and put a drain into each furrow, [thus making the distance between the parallel drains 36 feet,] the depth of which is regulated by the nature of the subsoil; but in general they are 2½ feet in depth. There being but few stones on my farm, I use tiles, which I find answer uncommonly well; indeed I would prefer them to stones, even admitting that I had them upon my farm, for these reasons:—Drains are cut in winter, and in most seasons, and particularly the present, it is almost impossible to get stones brought forward to the drains, and to induce women to fill them; besides, the injury which the land sustains by poaching with carts is considerable. Where land has a good declivity, stones, *when well broken*, will admit the water for a considerable time; but when land is nearly flat, tiles have a decided advantage for durability of drain. In covering in the tiles, I either put in some brush wood or mix a little of good earth with the subsoil, in order to allow the absorbed water to sink more freely into the drain. I am aware that some people have a prejudice against tiles, and allege, that in a few years, the earth above them will consolidate so much as to become impervious to water. I can only say, that I have used them for twelve years, and find the water making its way by them as freely as when the drains were first executed. With regard to the expense of draining a Scotch acre [four Scotch being equal to about five English acres,] with the tile drains at 18 feet asunder, and two feet in depth, it will cost for cutting and filling 3½ pence per rood of 18½ feet, or £2.6s. per acre. Prime cost of tiles is 40s.* per thousand, [which the editor says is too high.] Being seven miles distant from the kiln, I must add 8d. per 1,000 for carriage. Say that 2,700 tiles are required, their cost will be £6.9.6, making the total expense of draining £8.15.6 per acre. The expense no doubt is great, still I am of the belief, that upon all damp, heavy lands furrow-draining will repay, on an average, from 15 to 20 per cent on the outlay."

The lands, with us, which it would most profit the farmer to drain, are such as are marshy, and have not been exhausted of their fertility, of which there are vast tracts. Let us assume as data, the highest estimate of expense stated by Mr. Howden, which would be about $31 per English, or common acre.—The lands we refer to are now virtually unproductive. The outlay would bring them into the most productive state, say three tons of hay per acre, or its eqivalent in grain or roots. Almost any where in the valley of the Hudson, or near a market, the average price of the hay may be stated at $10 per ton, and the product of the acre at $30. Deduct from this 33 per cent, or one-third, for making and carting the hay, fencing, &c. and the nett profit of the acre would still be $20 per annum. Suppose there are 20 acres thus reclaimed from waste. In twenty years the nett profit would amount to 8,000 dollars. Deduct from this one half for triennial manuring, the outlay of the $620 for draining, and for incidental charges, and there remains the snug sum of four thousand dollars, or two hundred dollars a year, as a reward for the improvement. We honestly think this estimate is a safe one. In a field we last year lost an acre of potatoes, besides our labor, by reason of the water, coming from spouts and springs, keeping the ground wet, although it had been already imperfectly drained. Tile drains laid in autumn, have rendered it so dry, that the corn now growing upon it, received no particular injury from the heavy and continued rains with which we were drenched in the month of May.

---

* Draining tiles are made by Mr. Jackson, in Albany, and sold at $15 per thousand, with an extra charge of $7.50 per thousand for soles, if required. For the latter, however, hemlock boards are a good and cheap substitute.

Experiment with Corn.

"I have succeeded with the Dutton corn admirably," writes a Dutchess correspondent, "and have planted it this year exclusively. I planted last year four different varieties,—the Dutton, early Canada, (seed from Poughkeepsie,) eight rowed white, and corn said to be Egyptian, eight rowed. The Dutton ripened two weeks before the others, and yielded better. The cob is very large, and that would be objectionable, did it not take a good deal of corn to cover it."* It is well to remark, that after raising this corn eighteen years—the seed having been obtained from the gentleman whose name we gave it, we do not perceive any diminution in its early ripening property, which we ascribe to the fact, that we have always selected the earliest ripened ears for seed.

The Main Objects

Of farming are, or should be, two fold, viz: 1st. The greatest nett profit, with reference, however, 2dly, to the improvement, or at least to the preservation of the fertility, of the soil. He that wears out his land, by a parsimonius stinting of manure and labor, and close cropping, with a view to *present gain*, may be compared to the intemperate man who parts with his last cow, that fed his family, to gratify intemperate indulgencies. While good land pays always a liberal reward to labor, poor land often beggars its proprietor. The fault is often admitted, that our farmers cultivated *too much* land to cultivate it well; that they are parsimoneous of their expenditure to put it and keep it in good order; and that they rely more upon propitious seasons, good luck, and the special bounties of Providence, for good crops, than they do upon judicious management—upon the capital and labor employed in the improvement of their grounds. There is no sounder maxim for the guidance of the farmer, than that which teaches—"WHAT YOU DO, DO WELL."

Among our extracts in this day's paper, will be found a communication from "A Hampshire Farmer," which we copy from the Farmers' Magazine, contrasting the profits of the old and new system of husbandry, not only as verified in his own practice, but in that of Von Thaer, whom we agree with the writer in pronouncing pre-eminent in both the theory and practice of agriculture. And we beg our readers to mark the result:—"On the improved system the expense of cultivation is *double*; the gross product is TRIPLE; the nett produce is QUADRUPLE!

The great danger in the West,

Is, that the soil is so fertile, and so remote from the ultimate market for its produce, that there will not be sufficient inducements to industry, to ensure moral and physical health to its population. Where men can earn enough in two days to support them seven, they are too much inclined to spend the five in indolence, especially when the time comes, as come it may, that the many are sellers, and the few only buyers, of the products of the soil. And when a people are idle, from whatever cause, they readily, though often imperceptibly, slide into indulgences and habits which are the bane of individual and public virtue—unless their idle hours are appropriated to the improvement of the mind, and to the cultivation of a taste for rural embellishments, and the higher intellectual pleasures which emanate from literature and the science of agriculture. It requires far more philosophy and fortitude to resist the smiles of prosperity, than it does to bear the frowns of adversity. The latter is matter of necessity—while in the first we are left to exercise our own discretion. We have been led to these remarks, at this time, by the receipt of a letter from an esteemed friend in West Wisconsin, (Ioway) an extract of which we subjoin.

"With us in the west," says our correspondent, "the lands are rich and productive, with but little labor. A bountiful Providence has bestowed upon us one of the most fertile and delightful regions of the earth. Yet what are the bounties of Providence when unemployed by the labor and science of man? The mind is fallow, and the 'Garden of God' lies barren and overrun with weeds, and the rose and lily are choked by brambles, unless the assiduity and skill of man are exerted in developing the riches and beauties of nature.

"Until the recent *healthful* check of the 'times,' the west was intoxicated with the fell spirit of speculation. Labor and industry were looked upon as too slow and tame a way of making money. The 'royal way' of making a fortune by speculation infested all classes; and, as a consequence, the main pillar and ornament of a state was almost entirely neglected.

"But it is to be hoped, that these times for sober reflection may correct the delusions of the day, and impress upon the minds of the community this fact, that *there is no accretion to individual or national wealth, without the exercise of labor and skill*; and that that pursuit which 'feeds all,' and which can employ all, is at once the most independent and honorable."

This mention of the mania of speculation calls to mind the facetious relation of a brother Yankee, who made the grand tour of the "Far West" in 1836. After describing the fertility and beauty of the country, in glowing terms, he added, after a pause—"but, the *inhabitants* will starve! their work is altogether of the *head*, and not of the *hands*—they are trying to live by speculation more than by labor. Why, if you accost even a farmer in those parts, before he returns your civilities, he draws from his breeches pocket a lithographic city, and asks you to take a few building lots, at half their value, and earnestly presses you to buy as a personal favor conferred on you."

We are heartily glad to learn by our friend's letter, that the times are mending beyond the Mississippi, and that the public attention is being turned to our parent art, and a strong evidence of the truth of his declaration came enclosed, in the form of a twenty dollar bill, being the subscription money for twenty-two copies of the Cultivator.

Advantages of Science.

The British Farmers' Magazine abounds in communications, urging the establishment of a national agricultural institution. Scotland is particularly referred to as affording a striking illustration of the utility of such associations. Forty years ago, says one of these writers, Scotch husbandry was far inferior to that of England; but now, he says, it is manifestly superior. This is ascribed mainly to the influence of the Highland Agricultural Society, to the interest which the nobility and gentlemen of wealth have taken in diffusing agricultural science, and promoting agricultural improvement, and the establishment of museums for the exhibition of agricultural products, and models of agricultural implements.

Among these writers is a Mr. Handley, who has addressed a very able letter to Earl Spencer, who seems to be regarded as the pioneer in this praiseworthy project. The following extracts from this letter will not fail to interest the reader.

"Science—by which is to be understood, that knowledge which is founded upon the principles of nature, illustrated by demonstration—is the pilot that must steer us into those hitherto unexplored regions, where I am well convinced a mine of wealth is still in store for British agriculture. Chemistry, botany, entomology, mechanics, require but to be invited, to yield a harvest of valuable information to guide and to warn us.

"What has been the course adopted by our enterprising manufacturers? Had they been satisfied with the inventions which chance or the intelligence of their artizans might have discovered, in vain would they have struggled for the proud ascendancy which they now hold in the scale of the manufacturing world. How truly has it been said, that a Manchester manufacturer, who had been absent from England for the last seven years, would be ruined, if, on his return now, he endeavored with his former processes, to compete with the almost daily improvements of his indefatigable and intelligent rivals. How many thousand acres of land would the bleaching operations of Manchester alone require—what enormous capital would lie stretched for weeks unproductive on the sward—and how impossible would it have been to have completed the accumulated orders from foreign customers, had not chemistry furnished a cheap and rapid substitute?" * * *

The writer then adverts to the still disputed and unsettled questions, whether it is better to apply manure in a fermented or unfermented state? What are the principles upon which lime proves beneficial to lands? That nothing has been definitely settled upon the latter point, is evidenced by the fact, that "vast sums of money have been, not only uselessly expended, but much labor has been thrown away, in anticipation of beneficial results from the use of lime, which had the subject been better understood, might have been saved, but positive injury has resulted, which in thousands of acres has proved irredeemable." The same uncertainty is then pointed out in regard to the operation of gypsum, of salt; and also in many other interesting and important branches of agriculture, which can only be settled by chemical and philosophical research.

"*Botany*"—continues Mr. H.—"by which I would be understood to mean, not that branch of the science which is confined to nomenclature and classification, but which treats of the structure, the economy, the properties, uses, and diseases of plants, a correct knowledge of which tends to increase their number, and improve their quality, offers to the farm not less valuable truths than it imparts to the garden. The important labors of Mr. Knight, for instance, uniting as he does the ablest practice with the most profound science, and who has successfully cultivated the principles of the philosophy of vegetation, and thus improved the practice of horticulture, are alone sufficient to stimulate the agriculturist to extend his inquiries into the same field of interesting and useful discovery.

"The diseases of plants, whether arising from a superabundance or deficiency of juice, from its impure qualities, or from external causes, though at various times treated of by practical and scientific writers, are as yet very imperfectly understood.

"*Mildew*, *rust*, *smut*, and a variety of diseases familiar to every farmer, continue prevalent, and baffle all attempts to guard successfully against them, notwithstanding the numerous nostrums quoted as infallible.

"How they are originated or propagated is still matter of doubt; yet this knowledge is essential to the cure. The preparation and choice of seed, the manures applied, their nature and quantity, and the culture of the soil, are probably all, more or less, intimately connected with their existence, and, if carefully and scientifically considered, might furnish the remedy.

"The rotation of crops, and their comparative tendency to exhaust the soil on which they grow; their effects upon each other, in either furnishing or extracting the nutriment requisite for their successor; the theory of their excrementitious operation; the facilities they respectively afford to the propagation or destruction of noxious weeds; the still more important investigation as to the value of different plants and grasses as food: the most advantageous methods of cultivating them; their power to withstand seasons; the disposition of seed grown in southern latitudes to retain its propensity to early vegetation and maturity, though sown in the north; the benefits derivable from change of seed under all circumstances; the rules for selecting and improving new varieties, a subject so ably treated by Col. Le Coutier; and the habits, modes of growth, and peculiarities of weeds, which affect agriculture, and the most effective means of extirpating them; with many other similar subjects which it is unnecessary to enumerate, come within the legitimate range of the botanist's inquiries, and would render his co-operation invaluable to the agriculturist.

"*Entomology*, and that branch of *Zoology* which appertains to worms, furnishes another subject for scientific research, most interesting and important to agriculture.

"Lastly, I would refer to the benefits which would accrue to agriculture, were the *mechanism* of our implements more scientifically attended to. Mechanical men, possessed of talent competent to the production of the highest class of machinery, cannot be expected to draw upon their invention, unless, as in manufactures, they are stimulated to exertion by the assurance, that success in the improvement of old, or the invention of new machines, would ensure their reward, from premiums or general demand. Were such the case, it may be safely predicted, that the construction of even our simplest implements, which in fact constitute the mechanism of agriculture, would not be left to the contrivance of village smiths, but would command the attention of men whose intelligence would lead them to calculate the nature and amount of the various and frequently conflicting forces to be overcome, and whose mechanical skill would give to every implement its most effective shape."

Insect Enemies.

An interesting paper on the insects most injurious to our crops, by James Duncan, is published in a late Quarterly Journal of Agriculture. Mr. Duncan states, on the authority of Mr. Spence, the entomologist, that on a fair computation, 60,000 bushels of seed wheat are annually lost to the British farmers, by the ravages of the wire-worm, (*Cataphagus obscurus*,) and an expense incurred in dibbling and harrowing in where the seed is destroyed, of £15,750. The hop-fly (*Aphis humuli*,) sometimes occasions an annual loss of £415,000 to the British revenue, in the tax which the government imposes upon this article; and the turnip fly, (*Haltica nemorum*,) according to the Linnean transactions, has occasioned a loss, in the single county of Devonshire, of £100,000 in one year. The depredations of the grain-worm, in all probability, will this year cause an immense loss to the farmers of New-York.

As a preventive of the ravages of the turnip fly, Mr. Duncan says, "soot, ashes, &c. have been used for this purpose, but there can be no doubt that by far the most useful application of this kind is quicklime," strewed, we presume upon the young plants in the morning, while the dew is upon the leaves. Upon garden plants, as radishes, cabbages, &c. which are liable to be destroyed when in the first leaf, Mr. D. says that strong soap suds, thrown with a garden engine or syringe, is destructive to the insect; indeed that any liquid, even pure water, often thrown upon the plants, serves as a preventive—as moisture is prejudicial to them, they not attacking the plant but when the leaves are dry.

Five Hundred Sovereigns.

The Highland Agricultural Society have offered a premium of 500 sovereigns, "for the first successful application of steam-power to the cultivation of the soil," that is, to ploughing, harrowing and preparing the ground in an efficient manner. The total premiums to be awarded by the society the current year, amount to about 3,500 sovereigns, equal to $15,000, exclusive of more than fifty gold and silver medals.

---

* See letter of Mr. H. Clark, under Extracts.

Mulberry and Sugar Beet.

Mr. Randolph, chairman of the committee on agriculture, has made a report to congress, on the subject of giving governmental encouragement to the culture of the mulberry and the sugar beet, which embraces letters, upon these subjects, from gentlemen in different parts of the Union, and recommends the adoption, by congress of a resolution—

> "That the President of the United States be, and he is hereby, authorized gratuitously to lease, for the cultivation of the mulberry or sugar beet, for the term of ten years, any lot of land belonging to the United States, and not included in the unlocated or public lands."

Trifling as is the encouragement proposed, we are doubtful whether it will be granted. Agriculture is of no party, and has nothing to proffer to subserve the political or personal aggrandizement of legislators; and she is too humble in condition, and too modest in her demands, to expect aught from their liberality or foresight. She shares least in public bounty and patronage, though she contributes most to national wealth and national character. She cannot fawn, and will not menace, and consequently is neither favored nor feared.

The letters appended to the report, however, contain much valuable information on the choice of the mulberry and the management of the silk-worm.—We propose to notice some of the prominent and useful facts which these letters contain, for the benefit of those who are engaged in the business.

Joseph C. Parsons, of Northampton, cultivates five kinds of the mulberry. He prefers many varieties to the multicaulis, and gives a preference to the Canton, which he thinks will stand our northern winters, though we are somewhat constrained to doubt it.—From 100 of the Florence he produced, by layers, in one season, 1,747 plants. He laid in April, and laid the largest of the spring growth late in July. The plants were 18 to 24 inches in height. He thinks the multicaulis will not answer so far north; and that the mulberry should have a western, not a southern exposure. It seems he takes up and buries his seedlings in autumn. In regard to the beet, we learn from Mr. Parsons's letter, that the legislature of Massachusetts have proffered a bounty of three cents per pound for all sugar made in the state, from the beet root, for five years; he thinks the product can be made to equal 50 tons per acre—a pretty liberal calculation—which will yield, at only 4 per cent, in sugar, 4,000 lbs., and will entitle the manufacturer to a bounty from the state of $120 per acre. If we estimate the sugar at 6 cents per lb., its value will be $250, which, added to the bounty, will give $370 as the product of an acre, besides the beet cake!—the culture and manufacture to be deducted. A large profit, if half what is here stated should be realized.

George Green, of Belvidere, N. J., prefers the multicaulis, even though it should not withstand the winter, a fact of which he seems to admit there are doubts; "for," says he, "the roots may be taken up and buried in pits, like potatoes or turnips, or thrown into cellars until spring, and then replanted." He seems to depend upon the annual growth from the roots, and not upon trees or hedges; and he terms this "summer-cropping."

Hervey Hammond, of Lewisburg, Pa., prefers the multicaulis, as being easily propagated, tenacious of life, affording an abundance of foliage, which is gathered with facility, liked by the worm, and producing good silk. He recommends a light, high, sandy soil. Plant, he says, "in rows, six or eight feet asunder, and 12 or 14 inches in a row, and cut off the trees or tops within five or six inches of the ground, late every fall, and cover the stumps with earth, *so as to protect them from cold in winter*." Thus it would seem, that in Pennsylvania, three degrees south of us, it is recommended annually to cut down the multicaulis, and to cover the stumps with earth, *to protect them* from cold in winter—a practice which will at least be irksome and inconvenient to a northern farmer.

Jacob Corklin, jr., whose residence is not indicated, cultivates the white mulberry in hedge rows, and from the leaves on forty rods of hedge obtained three bushels of cocoons, which were worth $9. An acre, he says, will give 24 bushels of cocoons, or $72.—Mr. C. has raised the sugar beet. He estimates the expense of culture, including manure and rent, at $25 per acre, and the crop at 1,452 bushels of 50 lbs., and he considers them as good for farm stock as any other roots.

The fifth letter is from Daniel Stebbins, of Northampton. It goes largely into detail in regard to the mulberry and silk business. Mr. Stebbins recommends a poor, light, dry soil, for the mulberry. He thinks the multicaulis does not ripen its wood well, and is liable to be injured by the winter. He prefers the Canton, the seed of which came from the Canton mission, and which Mr. S. terms the *Canton* multicaulis. In the same soil and exposure in his garden, during the winter, the Manilla (common multicaulis) was much injured, the Canton and Asiatic unhurt, and the Chinese and Smyrna uninjured. The seed of the multicaulis does not produce its like, but plants with inferior leaves. A gentleman who kept an accurate account, ascertained that his silk cost him *two dollars* a pound, and it was worth in the market from six to seven dollars per pound. The bounty given by the state is about sufficient to cover all the expense of gathering the leaves, feeding the worms, and reeling the silk.

The 6th letter is from Chauncey Stone, Burlington, N. J., who recommends a loose dry soil, and an undulating or hilly surface, for the plantation. He prefers the multicaulis. He recommends planting in rows eight feet asunder, and the trees four feet apart in the rows—to manure and cultivate the ground, and when the season of growing is over to cut them down near the ground, to induce them to "send up seven stalks where one grew the prior year." An acre is estimated to produce 5,000 lbs. of leaves in a season, and a nett annual profit of $50.

C. F. Durant, we believe the celebrated æronaut, writes the seventh letter from Jersey city, Mr. Durant gives a decided preference to the Brussa mulberry—the kind introduced by Mr. Charles Rhind, from Brussa, in Turkey. He thinks the genuine cannot be propagated by seeds, but only by scions from the *same parent stalk*, produced by cuttings, inocculation or engrafting. Mr. Durand, we think, carries his theory too far. Seed will produce like the parent tree, if there be no other variety or species of the same genus growing in the vicinity, to affect the blossoms, or seed. And besides, *Mr. Rhind's trees were all produced from seeds*, and they certainly exhibit a sameness in wood and foliage. We are glad to find Mr. Durant concur with us as to the merits of our native mulberry. "The native black [red, rubra] is equal in quality," says Mr. D. "to the best in the world; the leaf is *smaller* than the Brussa, and is therefore inferior in *quantity*, because one hundred pounds of large leaves can be stripped at less expense than the same weight of small leaves." In propagating by the bud, Mr. D. recommends, that in the spring, when the buds have swelled almost to bursting, cuttings be made, of three eyes to each, and planted one foot asunder, in rows three feet apart. "Every farmer in the states south of 45° N. lat." says Mr. D. "can raise from 100 to 800 dollars worth of cocoons in the *spare room* of an ordinary barn or dwelling, and this would be considered *all profit*, if the silk is considered, like poultry, a collateral branch of farming." The total expense would then be the price of the trees, and the transporting the cocoons to market, which Mr. D. puts at $5.28, and leaving a nett balance of $105.72, which he considers a low estimate for a "small farmer." We agree with Mr. D. that the silk business should be a collateral branch of farming, and not a joint stock concern.

The next letter is from E. P. Roberts, editor of the Farmer and Gardner, Baltimore, who has been long engaged in the culture of the mulberry, particularly the multicaulis, and has grown the beet, though not manufactured sugar from it, to a considerable extent. Mr. Roberts recommends a sandy or gravelly loam for the mulberry, a high situation, and a southern aspect. He considers the multicaulis "beyond all comparison the most valuable species of mulberry grown;" and he would plant it on high ground, because there "the wood ripens better, and the *frosts* do not affect them so much as in *low* situations." Thus we see this inveterate enemy of the multicaulis, *Jack Frost*, pursues it even to the mild climate of Maryland.—And even the morus alba, which is generally affected by *our* winters, does not escape in Maryland: Mr. Roberts says he lost 70,000 plants of it in one winter. Mr. Smith propagates the multicaulis by cuttings of one bud, placing all but the tip of the bud in well prepared soil, inclining the upper end to the south in an angle of 45, pressing the earth around it, and watering if the weather is dry. As to the profits of the silk culture, Mr. R. estimates the expense of managing an acre at $203—the product at $1,333.33½—and the nett profit at $1,129.48½.

The 9th letter is from an esteemed friend, J. A. Downing, of the Botanic Garden and Nurseries, at Newburgh. Mr. Downing gives the preference to the "Chinese (*morus multicaulis*) and the Brussa,"—the first south of lat 42°, and the latter in all parts of the Union too cold for the Chinese. As the Brussa was first raised, on this continent, in Mr. Downing's immediate neighborhood, his opinion of its value is entitled to great weight. "The Brussa mulberry," says he, "is remarkable hardy, and produces a great abundance of foliage, larger, finer, and of superior quality to that of the Italian. It is yet rare in the country, having been introduced by Mr. Rhind, from Turkey; and the principal stock of trees (about 20 or 30,000) is now growing in this town. Silk has been manufactured from it of most excellent quality, which took the premium at the late Institute fair, at New-York. Mr. Downing recommends the cultivation of mulberry hedges, sufficiently wide apart to admit the free passage of the plough for culture, and of a hand-cart for gathering the leaves. Plants from 18 to 24 inches apart. In propagating by cuttings, Mr. D. recommends that pieces be taken from 6 to 18 inches long, and inserted in the ground the whole length, up to one or two buds.

Then follows a letter from Charles Kaigne, and one from Andrew T. Judson, of Connecticut. Mr. Judson's letter contains a compendium of all the information he had collected in relation to the silk business, in answer to queries which he had sent abroad. It is too long for our present purpose, and it cannot be abridged without doing it injustice.

Extracts from Mr. Pedder's report, which we have formerly noticed, on the culture of the beet, and the manufacture of beet sugar, closes the documents, saving an official statement exhibiting the imports and exports of silk and sugar from 1832 to 1837. From the latter it appears that the value of silk imported in 1837,—

Amounted to.......... ..	$14,352,823	
Do. exported,...........	1,207,802	
Home consumption,......		$13,145,021
Sugar imported, value, ...	$7,802,668	
Do. exported, ...	2,650,052	
		4,652,616
Amount retained in both, ...		$17,797,637

This pamphlet has confirmed us in the opinion, that the multicaulis is not suited to our northern climate; that the Brussa and native red must be our main reliance, if the latter proves hardy, as we think it will. It is unquestionably excellent for silk; and the reason it is not noticed by most of the gentlemen who wrote to the committee, is, that it was unknown to them, except by reputation. On the subject of the multicaulis, we subjoin an extract from the Southern Agriculturist, being a paragraph from a letter from a citizen of Charleston, J. H. May, Esq., to Dr. Johnson, without any view other than that of apprising our readers of the matter it contains. The letter is dated Sept. 1837, at Paris. The extract is as follows:

> "*Silk-worms.*—This is a subject of deep concern to our country. Prince and others have propagated and recommended the 'morus multicaulis,' as the best subject for that 'purpose—do all you can to destroy this opinion. Noisette, who has studied the morus more than others, tells me there is none equal to the common white, (morus alba); that the multicaulis, after four or five years, dies, or vegetates badly. This is experience—profit by it."

It is proper to say, that the causes of its dying, or vegetating badly, in France, may not exist in the United States.

Mode of analyzing Lime, and interesting facts in relation to its application.

"In eastern Pennsylvania, lime is the great source of improvement; and of this we have all the different varieties, I suppose, that can be named. We want some plain simple rule, by which any farmer may analyze lime, and be able to judge which of the different kinds is most useful to agriculture. We have primitive and secondary lime stone, also that which contains large quantities of magnesia, which we find very injurious to vegetation, and which I should like to detect before using it. Send us rules, in the Cultivator, to try lime, and you will oblige yours, &c.

"BENJ. F. BADOLET.

"*Pugstown, Chester county, May 25.*"

Before we reply to our correspondent, we cannot but repeat our regrets, that chemistry, so important in all the arts of productive labor, is not made a branch of instruction in the schools of farmers' boys, as it is in Germany, France, and elsewhere; and that we have no schools of instruction for them, in the theory and practice of husbandry, like those of Hoffwyl, Moegelin, Templemoyle,—of France, and of most of the German states. The benefits that would result alone from teaching the young farmer, scientifically, to determine the qualities of his soil, its defects, and the proper means of improving it by lime, marl and manures, would more than remunerate the public for twenty agricultural schools; or for suitable books of instruction in these matters, to every school in the nation. Science is almost indispensable to good and successful husbandry. See our *extracts* to-day. Orfila says—

> "It is impossible to lay down any general rules respecting the fitness of lime for the purposes of agriculture, because much must depend upon the peculiarities of soil, exposure and other circumstances. Hence a species of lime may be extremely well adapted for one kind of land, and not for another. All that can be accomplished by chemical means, is to ascertain the degree of purity of the lime, and to infer, from this, to what kind of soil it is best adapted. Thus, a lime which contains much argillaceous earth, [clay] is better adapted than a purer one to dry and gravelly soils; and stiff clayey lands require a lime as free as possible from the argillaceous ingredient.
>
> "To determine the purity of lime, let a given weight

be dissolved in diluted muriatic acid. Let a little excess of acid be added, that no portion may remain undissolved, owing to the deficiency of the solvent. Dilute with distilled water; let the insoluble part, if any, subside, and the clear liquor be decanted. Wash the sediment with farther portions of water, and pour it upon a filter, previously weighed. Dry the filter, and ascertain its increase of weight, which will indicate how much insoluble matter the quantity of lime submitted to experiment contained. It is easy to judge, by the external qualities of the insoluble portion, whether argillaceous earth abounds in the composition."

The diluted muriatic acid dissolves the lime. The insoluble residuum is clay or sand.

To detect magnesia in limestone, which, according to Tennant, renders the lime, when applied in large doses, prejudicial to lands, Orfila directs as follows:

" Procure a Florence flask, [a common half pint olive oil flask,] clean it well from oil, by a little soap-lees or salt of tartar and quick-lime mixed, and break it off about the middle of the body, by setting fire to a string tied round it, and moistened with oil [spirits] of turpentine. Into the bottom part of the flask, put 100 grains of the lime, or lime-stone, and pour on it, by degrees, half an ounce of strong sulphuric acid. On each effusion of acid, a violent effervescence will ensue; when this ceases, stir the acid and lime together, with a small glass tube or rod, and place the flask in an iron pan filled with sand. Set it over the fire, and continue the heat till the mass is quite dry. Scrape off the dry mass, weigh it, and put into a wine glass, which may be filled up with water. Stir the mixture, and when it has stood half an hour, pour the whole on a filtering paper, placed on a funnel and previously weighed. Wash the insoluble part with water, as it lies on the filter, and add the washings to the filtered liquor. To this solution add half an ounce of salt of tartar in water, when, if magnesia be present, a very copious white sediment will ensue; if lime only, merely a slight milkiness. In the former case, heat the liquor by setting it in a teacup near the fire; let the sediment subside; pour off the clear liquor, which may be thrown away, and wash the white powder repeatedly with warm water. Then pour it on a filter of paper, the weght of which is known, dry it and weigh. The result, if the lime *stone* has been submitted to experiment, shows how much carbonate of magnesia was contained in the original stone; or, deducting 60 per cent, how much pure magnesia 100 parts of the lime contained. If the burnt lime has been used, deduct from the weight of the precipitate 60 per cent, and the remainder will give the weight of the magnesia in each of the 100 grains of burnt lime."

The sulphuric acid dissolves the lime and magnesia, which pass through the first filter with the liquid. The salt of tartar precipitates the magnesia, leaving the lime in the liquid. The magnesia is the residuum upon the second filter.

We add some relevant facts in regard to lime, from the Domestic Encyclopædia.

In burning lime, a ton ought to be reduced in the kiln to 1100 weight; otherwise it is not sufficiently burnt. It will regain two-thirds of the lost weight, by exposure to air for a week or ten days—100 parts of lime absorb [and solidify] about 28 parts of water; and to regain its full proportion of air from the atmosphere, it requires a year or more, if not purposely spread out. All limestone of *primitive* formation, contains magnesia; all white *marbles* contain about ten per cent of magnesia. Put less of the magnesian lime upon your land, by about one-third, than of common lime.

The lands most benefitted by lime, are, 1. Rich black or brown friable crumbling loams, which abound with vegetable matter. 2. Low, rich drained meadows, that have formerly been bogs, and the black soil of which abounds in vegetable fibre. 3. Old pastures and commons, which have been under grass for time immemorial, and are first to be converted into arable land; but upon these, lime should not be repeated. 4. On moory, boggy, mountainous land, and on black peat earth. 5. On all other waste soils that have been overrun with fern, briars, bushes or wood, and which, though richly stored with vegetable food, have contracted an acidity, in consequence of their long rest, and the spontaneous growth of roots.

Mild lime, carbonate of lime, and marl, improve the texture of clays and sands, rendering the first less stiff and adhesive, and the latter more compact and retentive of moisture; and they improve all soils, not already charged with calcareous matter, by fitting them better to hold manures, and constituting a necessary constituent of most plants.

The soils which are not benefitted by quick-lime, are those which are poor, light and thin; those destitute of inert vegetable matter; strong stony lands; wet cold loams, and all lands which have not been sufficiently drained; and on stiff clays that are tenacious of moisture. Lime is only a manure of stimulus—not of nutriment.

Humus, Ulmin and Geine, are only different terms applied by philosophers to organic—to decomposed animal and vegetable matters, which constitute the fertility of soils, and the food of plants. In common language, they are MANURE under some of its modifications.

The Forty-fold Potato,

Derives it name, we believe, from its reputed prolific property. It is an esteemed variety for the table, and of recent introduction. An objection to its culture has been made, on account of the small *size* of the tubers, though they are not lacking in numbers; and this circumstance has induced us almost to discard them. A communication of Mr. Burns, in the May number of the Magazine of Horticulture, explains a common error in the culture of this variety, and suggests a remedy for the evil complained of.—This potato has many eyes, each of which produces a stalk; and where two or three tubers are planted in a hill, they give *too many stalks*, and *too many potatoes* for the ground they occupy. The consequence is, that the stalks are feeble and the roots small. The remedy is, to plant only one tuber of a medium size in a hill, the seed end of which, abounding in eyes, is first to be cut off and thrown away, when the residue may be divided into three parts, and planted in a hill. By this mode of management, the stalks will be few, have abundant pasture to feed upon, the tubers large, and the crop good. Such are Mr. Burns' directions; and to us they appear plausible, from the fact, that in the culture of the Rohan potato, a set with one or two eyes is found to be sufficient for a hill. We have counted forty-seven eyes in one Rohan; and we can readily believe, that this number of stalks in a hill could not produce many large potatoes. These hints may be useful in improving the product of other varieties of this valuable root.

Striped Bug and Turnip Flea.

At this season, our melons, cucumbers and other vines, are liable to be destroyed by the striped bug, in a few hours, and our young cabbages, radishes, turnips, &c. are liable to a similar fate from a small black flea. On visiting our garden a few days since, after several wet and cloudy days, we found many of our young vines, then in the first leaf, almost literally covered with the yellow bug, and our young cabbages also in the first leaf, in a fair way of being lost, in a few hours, by the black flea. We immediately sprinkled lime upon the vines and plants, and on the former took pains to put it on the under side of the leaves, and thereby saved our plants. Mr. Gordon, in the Tennessee Farmer, gives the assurance, founded on repeated experiments, that the sowing of two or three bushels of wheat bran, upon an acre of young turnips, will effectually secure the crop, as the fly prefers the bran to the turnip.

In the German and French Schools,

Are taught geography, history, chemistry, and several branches of natural science, drawing and music. These are taught in the common schools to the sons of farmers and mechanics. Upon these seminaries, well remarks Lord Brougham, "far more reliance is to be placed, [for the prevention of crime,] than upon all the provisions of the penal code, amend it as you may, and execute its amendments with whatever firmness and discretion you can bring to the administration af criminal justice." We pride ourselves as *freemen*—as being of a higher order than the *subjects* of the German and French monarchies, and yet we fall far behind them in what most ennobles our nature, and fits us for the greatest usefulness—*in the improvement of the mind.* Lord Brougham is right. Nothing tends more to prevent vice than habits of industry; and nothing serves to wed us to these habits—to give us pleasure and delight in them—so strongly, as a taste for, and advancement in, useful knowledge.

Axiom in Husbandry.

Plants, in general, will be found to deteriorate the soil, in proportion to their natural facilities of establishing a new progeny, [by stollens, suckers, or winged seeds,] at a distance from the deteriorated soil; consequently, such facilities, or the want of them, furnish good indications to the cultivator, of the extent or rapidity of the deterioration caused by particular species."—*Edin. Q. J. of Ag.*

As evidence of the correctness of the above, it is said, that young trees seldom send up succors till the soil has become exhausted of their peculiar food; but that when the soil becomes deteriorated, this is found to take place with the plum, pear, &c.—that the rose, to be kept in pristine health, should be removed to new earth at least every third year; that the removal of the raspberry is necessary every fourth year to preserve its vigor and fruitfulness, notwithstanding its propensity to send up succors; that the impatience of the strawberry to shift its location by runners, is demonstrative evidence of its deteriorating influence upon the soil. The necessity of alternating crops is further illustrated by the failure of the potato and the red clover, when returned too often to the same field.

The practical instructions suggested by these data, urge to the alternation of farm crops; to the change in pasture, or soil, of perennials which are found materially to deteriorate on the same site, as the strawberry, raspberry, currant, gooseberry, rose, &c. They teach, that the finer flowers of the florist, as tulips, hyacinths, &c. should be planted in fresh undeteriorated soil, at least every second year; that the soil should be rich and light, that their roots may extend themselves into fresh pasture, and that they should not be planted close, lest they rob each other of essential food. The deterioration of the potato in Ireland, a fact which the writer affirms, is ascribed to the repetition of the crop, on the circumscribed limits allowed to the peasant; and the diseases of the potato in Scotland, which, in some seasons, have been serious and alarming, are ascribed to over cropping.

Blasting Rocks.

We are not sure we are not retailing "*John Thompson's news,*" by inserting the following, from the Domestic Encyclopædia. It will nevertheless be new to some.

"Quick lime is of great utility in rending rocks and stones, when mixed with gun-powder, in the proportion of one pound of the former, well dried and pulverized, to two pounds of the latter. This singular property of lime was discovered, and is related, by H. D. Griffith, Esq. in the 8th vol. of the Bath and West of England Society, where he states, that the mixture above specified, caused an explosion with a force equal to *three pounds* of gun-powder; hence in those operations, one-third of the expense may be saved."

Agricultural Libraries.

W. H. Richardson, Esq. has sent us from Richmond, a printed list of about 100 vols. of agricultural and horticultural works, belonging to the State Library in that city, and asked us to give a catalogue of such others as in our opinion ought to be added. A State Library should contain all the standard works which appertain to rural affairs, especially if husbandry is the great business of that state. But as this description of books might comprise too large a catalogue, we will confine our recommendation to a limited number, with which, with the exception of the three last we shall name, we have a personal knowledge; and the characters of the latter stand so high, that we have no hesitation in recommending the entire list. And we prefer giving our answer through this channel, that others who wish, may avail themselves of the information which it contains.

We recommend, as suitable for a state or agricultural library, *besides the books now in the State Library of Virginia*, Chaptal's Chemistry, 1 vol.; Loudon's Encyclopædia of Plants, do.; Farmers' Series of Library of Useful Knowledge, not completed; Michaux's American Sylva, 3 vols.; Quarterly Journal of Agriculture, (Edinburgh,) 40 numbers received; Farmers' Magazine, (London,) 8 vols. published; Low's Elements of Practical Agriculture, 1 vol.; Domestic Encyclopædia, Cooper's revision, 3 vols.; Kenrick's Orchardist, 1 vol.; Manning's Book of Fruits, 1 vol.; Lorrain's Husbandry, 1 vol.; Memoirs of the N. Y. Board of Agriculture, if they can be had, 3 vols.; Transactions of the Society for the promotion of Agriculture and the Arts, 4 vols.; Massachusetts Agricultural Journal and Repository, 7 or 8 vols.; Foster's Atmospheric Phenomena, 1 vol.; Lindley's Guide to the Orchard and Kitchen Garden, 1 vol.; Entomology, by Kirby & Spence, 2 or more vols.; Ronalds on the Apple, 1 vol. 4to.; Williams' (or some other,) Agricultural Mechanism, 1 vol.; the agricultural works of Von Thaer, and of Sprengel (German) and Dick's, on the Veterinary Art. The Bath papers, British Agricultural Surveys, and the Georgical Essays might be added. They contain much that is useful, but more that is either irrelevant to our practice, or that has been rendered valueless by modern discovery and improvement.

M. Jauffret's discovery of a new mode of making manure, noticed in our last, turns out to be a humbug. The Farmers' Magazine for March, states, that after having for two years duped dozens of mayors, prefects, and other functionaries, and taken the cash of hundreds of subscribers, the patentee died one day, and it was *then* discovered, that manure cost twice as much by the new as it did by the old process.

Harvest beverage.—Put a tea-cup full of fresh oatmeal into a gallon of cool water—stir it previous to drinking, and renew the water when it is exhausted. It will keep the bowels and the skin in order, preserve a due temperament of animal spirits, and nourish and invigorate the whole system. It is both food and drink. Try it! N. B. Kiln-dried Indian corn meal may be substituted for oat meal.

To Correspondents, &c.

DISEASES IN POULTRY.

"A Subscriber," at Morristown, N. J. loses most of his poultry. "They thrive well for the first three weeks," after being, we presume, shut up to fatten; they then sicken, and in two or three weeks die. "On examination," says our correspondent, "I find the wind-pipe filled with small red worms, from very small to the size of a coarse thread." The disease is new to us; and in prescribing, we refer rather to preventive than cure. We would change the food, occasionally mingle salt with it—give a bath of sand and lime rubbish, and clean and whitewash thoroughly the inside of the poultry-house, a measure that should be adopted at least every spring.

CAPONS.

To capon cocks (we write in answer to the request of a Long Island correspondent,) make an incision with a sharp knife, under the lowest rib, with your fingers lay hold of the parts to be extirpated, and cut them away with sharp scissors. Put a stitch or two in the wound. So Mr. Willich directs. The effect of the operation is to increase the delicacy and fatness of the meat, and the size of the bird.

R. E. Russell, of Camden, S. C. asks us, among other questions, what crops or shrubs will grow under the shade of two oaks in his garden, which he is not willing to spare? What is the best compost for a coarse sandy soil which "bakes very hard in dry weather?" What quantity of seed should be sown per acre, of red and white clover, lucern, timothy, herds grass, orchard grass, ruta baga, carrot, &c.? And we give the subjoined brief answers. For the shade of the oaks, select the handsome native or other shrubs which are found growing, or are known to grow in the shade of other trees, including the common and variegated holleys, laurels, &c. or sow orchard grass, or plant strawberries—having first made the soil mellow and rich. From the sand "baking," it probably has much clay in it. Lime or manure, or vegetable mould, will tend to improve its texture and increase its fertility. Sow on an acre 10 lbs. red and 1 lb. white clover; or a peck to a half bushel of timothy, if with clover; or a like quantity of herdsgrass; 2 bushels of orchard grass; or 15 lbs. lucern; or 1 lb. ruta baga; or as much carrot seed as will furnish plants to stand four to six inches apart, in drills 18 inches asunder.

TO KEEP FRESH MEAT.

What is the best method of preserving meat, say shoat, beef and mutton, during warm weather?—*Tennessee correspondent.* Answer. Keep it in a refrigerator, an ice-house, well, or other place, where it will remain dry and in a low temperature.

QUESTIONS PROPOUNDED BY A. SUMNER, OF S. CAROLINA.

1. What would be the proper season, in lat. 34, for sowing ruta baga, to produce the best crop? Can best be decided on trial. We suggested sowing at the far south in the month of August, that the crop, congenial to a cold climate, might come to maturity late. But Mr. S. Weller, of N. Carolina, (see Cult. vol. III. p. 144,) prefers sowing the middle of July. His crop was more than 600 bushels to the acre.

2. Is a crop of ruta baga of more advantage to stock than sugar beet? That is best which is found best adapted to the soil and climate. If the sugar beet does well, be content, till it is found, by limited experiment, that the ruta baga will do better. They are about equal in nutrient properties. The Swede prefers a sandy, the beet a loamy, and both a rich soil, and good care.

ILLINOIS FARMING.

We have received, from a valued correspondent, a rather facetious account of the popular mode of farming in Illinois, which we take to be rather a caricature than a true portrait; and we are partly confirmed in this opinion from the fact, that our correspondent has sent us twenty-two subscribers from the neighborhood upon which he indulges his sarcasm. If the farming is as bad as he represents, we hope the Cultivator will help to improve it.

RENOVATION OF OLD MEADOWS.

A Dutchess correspondent asks what is the best mode of renovating old meadows, the soil of which is clay; and what crops are proper for a rotation upon such soils? He will find these questions as satisfactorily answered in our March, May and present numbers as we are able to instruct him here. Peas, oats and potatoes will serve as good fallow crops upon his clay, to precede wheat; and we would not advise that the land be restocked with grass seeds until the sod is perfectly rotted, the ground ploughed deep, and well mixed and pulverized. The beans extensively cultivated on clays in Great Britain, are the horsebeans, neither adapted to our climate nor our wants.

APPLES OF 1836.

We have received from D. B. King, of Waterford, two apples, sound, and of pretty good flavor, of the growth of 1836, and raised by E. Howland. What gives particular interest to the circumstance, is the mode in which these apples have been preserved. In the summer of 1837, Mr. King kept his apples *in charcoal;* and in overhauling this in May, 1838, he discovered the sound apples, which had escaped notice the preceding year. Charcoal has long been noticed for its antiseptic or preservative properties; and it has been particularly recommended to pack seeds in it, to preserve their vital principle, in passing the equator. Might it not prove an excellent material for packing apples in that are to be shipped to Europe, or the south?

A LARGE CALF.

Thomas Coleman, of Lewes, Del. writes us, that he has a calf which, at six months old, weighed *five hundred and forty-five pounds.* It was fed upon ruta baga, potatoes and the milk of its dam.

MAPLE SUGAR.

We have received a sample of beautiful maple sugar, from M. E. Vail, of Bennington, Vt. white, dry, and well granulated, about equal to second quality Havana clayed. "I made from *eight* trees," says Mr. Vail, "*one hundred pounds* of the same I send you." This is an average of 12 lbs. the tree. If this sugar is made, or refined by any new process, we would thank Mr. V. to apprize us of the mode. If our maple sugar was purified with animal carbon, a material now extensively employed in sugar refineries, and which may be produced any where with little expense, and clayed, the process of doing which we have published, it would be equal to the best Havana.

ANIMAL CARBON AS A MANURE.

We have received a hogshead of pulverized burnt bone, from the Mess. Stuarts, corner of Greenwich and Chamber-streets, New-York, to make trial of as manure. We noticed sometime since, that this article had been imported into Scotland from Sweden, and profitably applied to the soil. That which we have received has been enriched by having been used in the sugar refining, and is of course charged with mucilaginous matter. We have little doubt of its utility; and the price we understand it is sold at—25 cents the barrel—is certainly low enough.

BRUSSA MULBERRY.

We have received from N. Haight, Esq. of New-York, a compliment of four ounces of seed of the Brussa mulberry, imported from Smyrna. If our predictions should be verified, that this variety of the mulberry is more hardy than any other foreign kind, even the common white,—and that it yields a silk surpassed by none, it will be a great acquisition to the northern section of the union. We are in a fair way to have a good stock of plants. The 6,000 sold belonging to Mr. Ruggles' estate, and an equal quantity retained by Mr. Rhind, will probably make 100,000 plants the current year; and add to this ten thousand plants sold and retained by Mr. Haight, and the seed furnished by him, and it will be seen that our supply will soon be abundant, if on further trial it shall be found to realize the high expectations which some have formed of its hardiness and excellence.

ROHAN POTATO.

We received several recent applications, by letter, for a tuber or two of these potatoes, which we could not grant, for the reason that we had planted our whole stock. This potato may be had of us, in autumn, in quantities.

ITALIAN WHEAT.

Our friend, Mr. Hathaway, of Rome, persists in cautioning the public, against soaking the Italian seed wheat more than 20 minutes in *strong brine,* lest it destroy the germinating principle. He cites five instances in proof—in one 100 grains were soaked 1 hour, and 42 only germinated; of that which was soaked 3 hours, nine-tenths failed; and of two other parcels soaked 6 and 9 hours, all was killed. Mr. H. ascribes this result to the thin skin of this grain. We repeat that the practice of steeping seed wheat in pickle is common in both Europe and America—that we have practised it nearly twenty years, and that the cases cited by Mr. H. of its injurious effects, are the first that have come to our knowledge.

PEAT OR TURF.

We have sundry inquiries from O. C. Freeman, of Detroit, on this subject, which it is difficult for us to answer, without a better knowledge of the material he describes. The swamp, Mr. F. informs us, has an upper stratum of 14 to 18 inches of what he terms peat, which is underlaid by 3 or 4 feet of muck. He has cut a drain two feet deep. The drain should be three or four feet deep, and below the muck, if practicable; and if this does not lay the ground dry, drains should be made round the borders, and others diagonally from the main one, if necessary. When laid dry, the upper stratum, which we suspect is a compound of ligneous matter, roots and muck, may be either cut and dried, and used as fuel, or converted into manure, by burning, mixing with lime or stable manure. We refer Mr. F. to the three last numbers of vol. IV. for ample instructions upon this head.

SUCCORING CORN.

"Should Dutton corn be succored?" We answer—the same rule will apply to the Dutton that applies to other corn—it increases the *proportion* of sound grain, and somewhat accellerates the ripening process—though it does not, we think, increase the *quantity,* while it sensibly diminishes the *good* forage, and causes additional labor. We do not succor our corn.

STRAWBERRIES.

Some of our correspondents complain, that their strawberries do not fruit, though they flower finely.—R. Hoyt, of Danbury, Ct. has asked us to suggest a remedy. Most of the species of this fruit possess both sexual organs in the same blossom, like the apple; but there is one kind of the hautboy, at least, and perhaps more, that bear these organs in separate flowers, and on separate plants. The male, bearing the stamens, never produces fruit; and the female, bearing the pistil, will of course not fruit, unless within the fruitifying influence of the male, the blossoms becoming abortive.—To prosper well, the two sexes should be planted together, in the proportion of one male to about ten female plants. The selection is most readily made when the plants are in flower, and they should then be marked, to be able to take the due proportion of each from the stole. The male flower is larger than the female, and on examination will be found to be devoid of pistil. As August and the early part of September is the best season for planting beds of this delicious fruit, we propose in our next to give directions for their culture, and to notice some of the most esteemed species and varieties of this fruit.

Mr. Myers, of New-Brunswick, will please forward the *explanation* of his drawing of the *Centrifugal Dessiminator.* We refer to the parts—the letters in the drawing—and the price of the machine.

Acknowledgements.—A bundle of Chinese mulberry plants, and six ounces of Chinese mulberry seed, from D. Hagguston, Watertown, Mass.; Portuguese spring wheat, from L. Ashburner, Stockbridge, Mass. water melon seeds from J. N. Pallain, Georgia; Small's improved plough, from W. Small; Bushnell's improved drill-barrow, from the patentee; gigantic wheat from G. C. Thorbun, New-York; seeds of prarie flowers, from E. Dunn, Esq. Little Rock, Arkansaw.

CORRESPONDENCE.

Freaks of Nature.

Mendon, Ill., May 9, 1838.

Sir—As you are endeavoring to collect and distribute among your numerous patrons, not only all that which is useful and instructive, but also that which is curious and entertaining, I send you the following, not that it possesses either of the above characteristics, but is simply one of those freaks of nature, which so often occur in the distribution of the different varieties of plants in the vegetable kingdom, and which are seldom noticed.

In the month of September last, while engaged in cutting up corn in a field in which the prairie was broke two years before, I observed that there was occasionally a bunch of prairie grass growing, which is often the case if the prairie is not well broke at first, and the future crops well taken care of. On one of these bunches I noticed a number of dwarf ears of corn growing, which excited my curiosity. The bunch of grass grew near a hill of corn, and differed not from other prairie grass, and the corn grew where the grass seeds, if it can be said to seed. The ears were six or eight in number, three or four inches long, rather imperfect in their formation, kernels smaller than those on perfect ears I regret it much that I did not preserve some of the ears and plant this year with prairie grass, out of curiosity, to see their progeny, but it was set up with the other corn, and before I thought more of it, was carried away, and I saw no more of it.

TIMOTHY DEWEY.

To prevent the ravages of Rats in Grain.

How to prevent the ravages of rats in grain after it is housed, has been an inquiry of long standing. We can never exterminate them to such a degree as not to apprehend their incursions, for a horde of these troublesome visitors will often make their appearance when we least expect them. Instinct points the way to where that provision best suited to their nature is found most plentiful. We have often found, when we went to thrash, our oats cut and cleaned by them, and the straw rendered unfit for any purpose whatever, even the subservient one of litter.

But every evil has a cure; and I have found common elder to be a preventive, and have tested its properties as an anti rat application. When the grain is to be packed away, I scatter a few of the young branches over every layer of bundles, being mindful to have them in greatest abundance on the edges of the pile. The drying of the twigs will give the grain an odour not relished by the vermin—which scent in no wise detracts from the quality of the straw for horses, as it makes no difference with them. I have tried it successfully, a number of years, in wheat, oats and corn.

RUSTICUS IN SOLEA.

Improvement of the Mind.

Watertown, May 18, 1838.

Dear Sir,—I read the letter of Mr. Robinson to Judge Buel, to which you referred me, with pleasure; the object is highly praiseworthy, particularly in a government like ours, where all power is vested in the people. Whatever has a tendency to elevate the character of the working, or productive class of men, adds stability, and a fair promise of durability, to our institutions. Had Adam not eaten of the forbidden fruit, I think each individual of our race would have been engaged in promoting the common good. But it is not so; we are selfish, and all we hope or look for in the best of men, is, that in pursuing their own interests they may select such objects as may also be useful to others, and have a tendency to raise the standard of human character; but I doubt if persuasion only will, or can produce the desired effect.

Men are apt to arrange themselves into two classes: one live by their labor, the other attempts to live by their wits; or, the one earns, and the other appropriates the earnings of the former to their own use, availing themselves of the follies and vices of their neighbors, as a legitimate means of the appropriation. Nothing would be less like a good general than to trust to his eloquence to persuade the enemy not to invade his territory; his true course would be to make himself strong; and if labor should become honorable and popular here, it must be effected by raising the mental condition of that class who labor. Many benefits would result from such a change. You want to bring to the aid of the farmer and the mechanic a most powerful auxiliary, by enabling him to apply more science and skill to his every day business; you would create in him a consciousness of his own true dignity; you would raise him above petty tricks and frauds, and greatly lessen the drafts upon his earnings to pay the price of litigation. I am well convinced that increased intelligence with the laboring class of mankind, is the only true remedy. For one, I have always considered that man the greatest, and the best, who, by his own exertions, adds the most to the aggregate of human happiness, and I regret with you, that modern habits seem highly to encumber the earth with a very useless set of men. You well say that labor is the origin of wealth. Every thing that administers to the necessities, the comforts, the pleasures and luxuries of men, results from labor. Extend then the benefits of education to the farmer, the mechanic, and producer; and if any man has a child endowed by nature with more than ordinary mental powers, let him early encourage that child in the pursuit of useful industry, and bestow upon him all the advantages of education that his situation permits; the more equal the distinction of wealth, the greater the sum of happiness. Wealth and character are usually more equally distributed where idleness is considered a vice and industry a virtue. I am, dear sir, yours truly,

WM. SMITH.

To preserve Roots in Winter.

Leesburg, Loudoun Co., Va., May 22, 1838.

Sir—The farmers of this county have for the last two years turned more of their attention to the example set by their northern friends, in raising roots. I, for one, was quite successful in *raising* the last year, but lost nearly all during the winter, for the want of a *properly* constructed root-house. My motive in writing this, is to beg the favor of you to give, in your next No. an approved plan for one, on a small or large scale, as your judgment may suggest. Two winters ago I used my cellar for the purpose, but during all damp weather the smell from the turnips was disagreeable, and caused a constant apprehension of sickness.

I am quite a convert to the profitable use of potatoes in feeding milch cows and hogs, and am now preparing for a large crop, which I hope I may be enabled to keep, from the information I may derive from your valuable paper. Very respectfully, your ob't serv't,

W. C. SELDEN.

Remark.—Root cellars should be constructed under barns, or other out-buildings, with a view to occasional ventilation. When the out-building is upon the slope of a hill, the entrance may be made large enough to admit a cart, or otherwise the roots may be deposited through a hatch-way, or a trap-door in the floor. But the main crop may be best deposited in pits, in dry situations, of three feet or less in width, the roots to be raised to a ridge in the centre, well covered with earth, and ventilating holes made in the crown of the pit with a bar, to let off the rarified air. Roots should not be housed or placed in a pit when wet with rain.—*Cond.*

Rotation of Crops.

Clinton College, Tenn., April 27, 1838.

Hon. Jesse Buel—Dear Sir,—Under the head of "Rotation of Crops," in the last number of the inestimable Cultivator, you remark, "We would accept it as a particular favor, and the public would no doubt be greatly benefitted, if some gentleman in the south or west would furnish us with the courses adapted to those sections." Fully impressed with the importance of the motto, "Help one another," and conscious of the *great value of free inquiry and communication*, I am prompted to comply with your request as far as I can; though I should much prefer that the spirit of agricultural improvement in this quarter were sufficiently up to stimulate some one better qualified than myself to give you the desired information.

Indeed, agriculture in this part of the Union has heretofore been so little studied, that the rotation of crops *best* adapted to the nature of our soil and climate is perhaps yet unknown among us. We have, however, some who wish "to improve the soil and the mind," and who have devoted some attention to the improvement of our agriculture: consequently, I am able to give you what I deem our *best rotation*, which has yet been practised here. And here it is but justice to remark, that for improvements of this kind, our people are almost, if not entirely, indebted to the Cultivator and Tennessee Farmer.

In the outset, it may be stated, that experience has sufficiently proven, that the articles of cotton and tobacco cannot be cultivated to much advantage in any part of our state, and that in most parts they are of no profit at all; hence they may be left out of our rotation of crops. Our surface is vegetable mould, strongly impregnated with lime, resting upon a clay substratum.

It is true, we have some mountain land, of a sterile, barren nature, void of lime, and possessing but little mould; but the generality of the inhabited and tillable land is of the kind before given. Thus, nature made our soil fertile, but it has been much deteriorated by neglectful culture: still none of it is so far exhausted, that it may not be reclaimed by clover alone. And this country and climate being by nature adapted to the production of stock and grain, the rotation should consist of wheat, rye, oats, Indian corn, clover, beets, turnips, potatoes, &c.; while our wood lands should be well set in timothy and herds grass for meadows, and blue grass for pasture. Then suppose a farmer have 150 acres of land which he tills. It should be divided by fences into three equal parts; one of which should be sown every year in wheat, rye or oats, (clover and timothy, mixed, being sown with or upon the small grain.) Then the rotation would stand thus in succession: 1st year, small grain; 2d, clover and timothy; 3d, Indian corn; 4th, small grain; and so round again. Thus all the tillage of any portion would take place every third year; and by this plan our lands improve in fertility at a rapid and cheap rate; the clover being always ploughed in when it is two years old. We can here enrich land cheaper and faster with clover than by any other mode of manuring. It is well to remark, that if the farmer choose to sow rye or oats instead of wheat, during the year of transit from corn to clover, he can do so with propriety, for clover will prosper among them as well as wheat; but the point of material importance is this, he ought not to harvest more of them than enough for seed. Because, if he will graze them, from the time they are eight or ten inches high, with horses, cattle or hogs, (especially the latter,) his stock will thrive on them nearly or quite as well as on clover, while they are manuring his land. The grazing should be conducted in the same manner as upon blue grass, clover, or any other pasture.*

In this way, his oats and rye afford as much immediate profit as if they were to ripen and to be harvested; besides, the farmer reaps a future profit in the improved condition of his soil, from the circumstance that the stock fatten the soil while fattening themselves.

It is for the interest of the farmer not even to put a third of his land in corn, as the above system imports; but of that third a portion should be occupied in beets, turnips and Irish potatoes, for these products prosper well here, and are more economical in the rearing and fattening of stock than corn. Then, the farmer would till fifty acres yearly in corn, beets, turnips and potatoes, and each portion of ground would be tilled but once every three years.

It may be well to suggest that all the stable and yard manure should be *put in the hills or drills* of corn, beets and potatoes, instead of spreading it broad cast.† By applying it to the hills, or immediately where the plants require it, *all* that is put on the ground is of *immediate* benefit to the crop, and thus too you are enabled to supply each plant more abundantly than a given amount of manure would otherwise do. Your turnips, if sown broadcast, must of course be manured in the same way; but if in drills, the manure should be also in the drills. By thus manuring in the hills or drills, your immediate crop is increased to the highest perfection in your power, while you are thus enabled to keep less ground to obtain a given amount of produce, so that more of your land can be in clover, yielding a profit, while it is undergoing a cheaper and more speedy fertilization. Lime should be spread broadcast upon the high points of the field, where the soil has been washed away.

Thus, hastily, I have given our best rotation, and I must conclude by asking you some questions.

1st. What are the best authorities on horses, sheep, and swine? Can they be had in Philadelphia; if not, where?‡

2d. What is the price of Berkshire pigs, and how could they be transported to Nashville, Te.?§

3d. Is the constitution of the State Agricultural Society of New-York published in pamphlet form or otherwise? If so, please send me a copy. If not published, the western country would be benefitted by the publication of it in the Cultivator.||

With high regard for your efforts, I am, sir, your ob't serv't, FRANCIS H. GORDON.

The improvement of the Mind leads to the improvement of the Soil.

Farmington, May 19, 1838.

J. Buel, Esq.—Dear Sir—One of your correspondents, Mr. Robinson, asks what can be done to elevate the condition of the cultivators of the soil?

The zeal he evinces in his communication to you on the subject is worthy of all praise, and his suggestions may be the means of awakening a spirit of inquiry, and thus be the means of effecting much good.

It is true, the *farmer's* calling has been despised, and mainly, as I believe, because the ignorant and refuse of the people were principally the operators, and because the profits of the business were so small, as not to tempt the active and enterprising to engage in it. If I am right in this view, the remedy is plain; it is, to induce men of intelligence to enter into the business, and to make it in a pecuniary point of view profitable.

Now if the mass of the people can be made to see that the cultivation of the soil is equally profitable, or more so, than mechanical business, we shall find no lack of hands, and of the right sort too, to engage in it.

Science, applied to agriculture, has, in England and Germany, effected this object. The new system of husbandry introduced there is not only enriching their soil, but it is gradually making it the most profitable business of all. The dissemination of knowledge here then, and the inducing educated men to enter upon the business, are the means to be used to produce the desired results. Newspapers devoted to agriculture are the vehicles to be used to convey this knowledge to the people; these should be encouraged; every subscriber should induce his neighbor to take one, and use every honorable means to increase the subscription list and extend the circulation, that the conductors of such works may devote time, and labor, and knowledge, and talent, to make them worthy of patronage.

I have thought, instead of forming agricultural societies, (the benefits of which for the most part are temporary,) a more permanent source of good would be to endow agricultural schools, where young men would be sent to acquire knowledge, and to study the art as a science, where practice should be united with precept, where *professors* of every branch of rural economy would lecture, and where every means should be used to instil into the minds of the students a love of the science, and to fit them to be useful to themselves and to the community. To such institutions the rich would be induced to send their sons, as not only invigorating their minds and bodies, but as a means to acquire an accomplished education. The poor, as giving them an useful education, and to enable them to make their way through life; and thus should we rear up educated men, well imbued with this peculiar knowledge, many of whom would choose agriculture as their business, and devote their lives to the improvement of their profession, and thus produce the results your correspondent seeks for.

It is by knowledge thus applied in Europe, that agriculture has made such advances there, and with the enterprize and perseverance of our people may we not hope to overtake our fatherland, and even rival it in improvement.

And why should we not have such schools to teach the art scientifically? Is it not the first and most important employment—that on which all others most emphatically depend, and a thorough knowledge of which is more difficult to obtain than almost any other, and requiring a capacity, too, to master it, of as great a stretch as any other? but having once acquired such an education, the field is open for talent and enterprise in which a rich harvest of honor and usefulness may be reaped; and the successful occupant of which may acquire more solid renown than the great leader of armies, or the statesman at the head of the councils of the nation.

If you should find any thing in these suggestions of any value, you are at liberty to use them in the way you shall deem best. My object will be obtained if any thought I have expressed shall prove a stimulant to others to aid a cause which in its results will be so cheering to our country.

I think I can already see a spirit arising in our land which will not scorn to labor until our land shall become eminent in this branch of knowledge.

Respectfully yours, EGBERT COWLES.

Mode of preventing or curing the Murrain.

In p. 68 of our last vol. we published a communication from J. Smealie, descriptive of a fatal disease which prevailed among cows. Our remarks upon it will be found in p. 79. That communication induced a Maryland farmer to inform Mr. S. *how to save his cows* After repeated trials of the prescription, Mr. Smealie has had ample proofs of its efficacy, and has sent us the correspondence, which we insert below.—Thus, it will be seen, the Cultivator has been a means of saving several valuable cattle; and the letters which follow, we have reason to believe, may be the means of saving hundreds more.—*Con. Cult.*

Union Town, Carroll co., Md., June 12, 1837.

Respected Stranger,—In the last Cultivator I saw your letter, describing a disease which prevailed among your cows. My object in writing to you is to inform you of a preventive of disease, which I have used for the last two years with success. It is simple. You may try it if you think proper. I tie my cow in the stable, then let a strong man hold her by the nose and horn, then take the paddle we commonly use for greasing the wagon, dip it in the tar bucket, taking up as much as will stick to it, say from a gill to half a pint, open the cow's mouth, and put it as far back on her throat as possible without hurting her; hold the paddle in her mouth long enough for her to work the tar off of it. I do the same to every cow, and repeat the operation every two or three weeks the year through, at the same time rubbing a quantity of tar about the cow's

---

* This is a new, but, we are inclined to think, a good, suggestion.

† We must dissent from our correspondent. Manure is intended not only to benefit the crop to which it is applied, but subsequent crops. And *where* does the corn crop want it? In the circumscribed space occupied by the hill? The roots, which take up the food, soon extend beyond these limits; and we think that if dunging in the hill gives the greatest *immediate*, spreading the manure broad cast imparts the greatest *ultimate*, benefit, even to the corn crop; and that it benefits most if spread, and commingled with the whole stratum of soil.

‡ "The Horse," by the British Society for promoting useful knowledge, is one of the best works upon this animal.—The same society have made a valuable publication on sheep. Both of these books can be obtained, no doubt, through Judah Dobson, bookseller, Philadelphia. We know of no distinct publication upon swine, though most of the British agricultural writers treat of them.

§ See Bement's letter in No. 3 of the Cultivator; for price. They might be sent to Nashville by water, via Lake Erie, the Ohio canal, &c.

|| This request shall be complied with.

horns and face, forehead and nose; likewise smear plenty of tar about the manger and troughs. Before I commenced with the above remedy, I lost a number of my best cows, but we called the disease the horn distemper or murrain. I have had cows taken when in fine order, I might say almost fat enough for beef; they would linger a few days and die—the horns when examined would always be hollow, and mostly dry—urine sometimes bloody. From the circumstance of your cows voiding bloody urine, I think it evidently the murrain your cows are afflicted with. It is a distemper caused sometimes by cattle drinking impure water. I would advise you to try it, always bearing in mind that it is necessary for the cow to swallow a good portion of the tar. Since I have used the tar, about two years, I have not had one of my cows diseased in any way, and one of my neighbors, whose cows were formerly diseased, has used it for a long time with the most complete success. I give the tar to horses, sheep and hogs, and think it good for them.

If you should think it worth while to try it, and should succeed, I would be glad to hear from you, that is, after you have tested it fully. Direct to Union Town, Carroll county, Maryland.

Since writing the above, I think it necessary to state, that I do not think the tar will be so likely to cure a diseased animal, but as a preventive of disease among stock of any kind I think it unrivalled, particularly for cows.

Your friend,
JOSEPH COOKSON.

Princetown, Schenectady Co., April 21, 1838.

Dear Sir,—Ten months have nearly elapsed since I received your letter in reply to one of mine which was published in the June number of the 4th vol. of the Cultivator, giving an account of a disease that prevailed among my cows, which I did not then know was what is called *murrian*, until informed by Judge Buel and yourself. My object in now writing you is, first, in accordance with your own request; 2dly, to return you thanks for your promptitude and kindness in writing me, which I now do unfeignedly and gratefully; and, 3dly, to inform you of the success of your prescription, not only in my case but also with several of my neighbors. I can now go a step farther than you ventured to do, that is, I can recommend the use of tar, not as a preventive only, but also as a cure for the above disease. You will be able to judge from the following facts: I commenced, according to your directions, immediately on the receipt of your letter, from which time back to the date of mine already referred to, none of my cattle had been taken sick, but in three or four days after they had received the first dose one of them was seized. I first observed her in the morning, and immediately gave her another portion, perhaps double in quantity to what you recommend. At night she appeared to be no worse, but I gave her yet another dose; next morning she was evidently much better, and soon got entirely well.

This was the last sickness of any kind to which any of my cattle have been subjected. The distemper has prevailed in this neighborhood, more or less, for a number of years, very few recovering; and where it found its way among a stock, it has sometimes swept the whole which the owner possessed. Application was made to me by three of my neighbors, to all of whom I recommended the use of the tar, and in every case the result was a complete cure. The first, (who like myself had been contending with the disease for a considerable time,) had a cow so far gone that she was unable to stand, and was blind, yet, contrary to all expectation, on a liberal application of the tar she recovered. Another had one of his cows violently seized, (he well knew the trouble as an old acquaintance, it having nearly swept him once before,) he applied the tar a few times in large doses, and she soon recovered. Another had lost two cows, but since he commenced giving tar, which is about six months, the others have remained in good health. These are the only cases that have come to my knowledge, but the result has been uniformly such as I think will warrant its publication.

Your letter has been read in the office of the Cultivator, and the result of your prescription in my own case has likewise been stated. A request has also been made for your letter for publication, which I have promised, on condition that you make no objection, which I think very improbable, after your prompt communication to an entire stranger. I will, however, wait until the last of May, and if I do not hear from you before that time, your letter will probably appear in the June number.

I am, dear sir, your much obliged well wisher,
JAS. SMEALLE.

Mr. Joseph Cookson.

Corn Stalk Fodder.

Knoxville, Tenn., May 13, 1838.

J. Buel, Esq.—Sir,—Our farmers generally pursue the old plan of stripping the fodder off the corn stalks, whenever the corn is sufficiently matured to do so.—The stalk is very seldom cut off near the ground, and we know very little of saving corn and fodder in that way.

I have been under the impression that the blades would become so much dried before the corn would be sufficiently matured to cut up, that the fodder would be of little value. I would be glad of some additional information on this subject, and also as to how long the stacks are left standing in the field after cutting?—Whether the corn is taken off the stalk before housing? and any other information on this subject you may please to communicate in some subsequent number of the Cultivator.

Very respectfully, your ob't serv't.
MAT. McCLUNG.

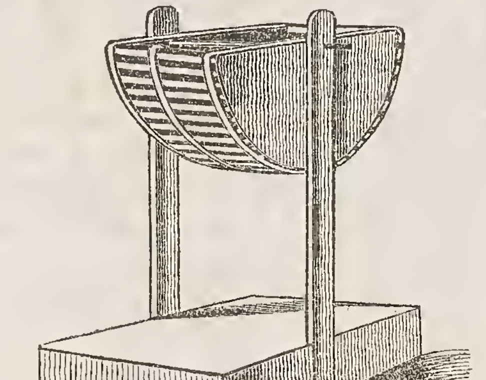
Remarks.—Our practice is, to cut up our corn as soon as the grain becomes glazed, or hard upon the surface—while the leaves and stalks are generally yet green and succulent, and to set it immediately in stooks. Being gathered in this succulent state, and protected in the stook from the injurious effects of the weather, it dries moderately, and retains most of its saccharine and nutrient matter. The corn may be picked from the stalk in twelve or fifteen days, if the weather is favorable, though the stocks require a longer time to cure, before they are housed. When the corn is taken off, we put the stalks into small stacks, so as to expose all the but ends, which have become wet by standing in the fields, to the drying influence of the winds. The grain unquestionably derives more benefit from the stalk after it is cut up, than it does from the stock, after the latter has been stripped of its leaves, its elaborating organs, as practised at the south. The stook, containing 80 to 90 stalks, is tied above the ears, which latter keep it sufficiently open to prevent the grain heating or moulding. It should be remembered, that our corn stalks are pigmies, compared to those which grow in Tennessee. See a memorandum of our experiment at p. 142, in our 4th vol.—*Cond.*

Potato Washer.

Yorkville, Whitestown, April, 1838.

J. Buel,—Sir,—I send by the bearer a model apparatus for washing potatoes and other roots. It is an old affair, therefore I am so much the more vexed to still see brother farmers washing their potatoes in boxes, troughs and baskets, when for the value of one good oak basket they can construct a washer that will last 15 or 20 years. The cheapest way is to take that rude plank you have kept so long because it was so fine, and strike two circles of 40 inches radius, depth 20 inches of course, and saw them out; now take one of your old barrels, if oak so much the better, the staves are exactly the right shape, a little too long perhaps, 28 inches is long enough, place the heads or ends that distance apart, and nail on the staves three-fourths of an inch asunder, over which nail three strong hoops, one on each end and one in the middle; now bore a two inch hole in each head two inches below the compass dot, through which put a shaft, which may be put through or notched on to two posts; the posts may be set in the ground, or, if it is desirable to render the whole moveable, they may be attached to a timber or plank floor. There you have it, now we will try it. Pour the potatoes in over one end to keep its equilibrium, then dash on a bucket of water, and facing one end, and with a hand on each side rock it to and fro, so slow that the potatoes follow the motion; when they appear to be all wet, put in another bucket of water and let them drain; so tip it down, (it being high enough to set your basket under,) and they will slide out freely. With a washer of this kind, any one who can carry a bushel of potatoes can wash, with two buckets of water, two bushels in less than two minutes.

[Fig. No. 38.]



It is obvious that it will wash ruta bagas, beets, &c. equally well, and apples also. There you have my account of the matter; but it is no use to say so much about it; my neighbors see me using it frequently, and acknowledge it is a grand thing, and then go straight home and continue the use of their baskets and troughs as before. 'Tis this that vexes me, because every one of them can make one if they will.

Respectfully, H. G. BALIS.

P. S. I wish to ask you one question. If my basket will hold a bushel of grain even full, ought it to be considered a fair bushel of potatoes if I fill it heaping full? [Yes.]—*Cond.*

Cure for Ring Bone.

Mr. Editor,—Are we not individually called upon, when we become acquainted with any knowledge which by a more extended diffusion will promote the interest and welfare of those around us, to make known the same to the public?

Feeling this to be a duty, I would direct the attention of all gentlemen who are raising horses to that distressing complaint, viz. the ring-bone.

Having in the early part of my life paid considerable attention to the raising of horses, but finding them subject to so many complaints, and especially that of the ring-bone, I was much discouraged in the enterprise, and was led to ascertain, if possible, the causes of that complaint, and if any remedy could be found. From all the information that I could obtain from different authors on the subject, and from my own experimental knowledge of the complaint, I was led to conclude that there were various causes for the complaint—that colts which are kept confined in a stable, and the floor cleaned off daily, are more liable to be affected with ring-bones, than those that are kept on the ground or on floors well littered. Low keeping, by weakening the joints, has a tendency to produce them. In young horses they are generally occasioned by sprains, which are made by being rode or drove too hard, running in the pasture, or leaping fences.

After hearing the above statement as to the causes, the reader may with propriety inquire, what composes the ring-bone, and whence does it originate? In answer to this inquiry—I have found it to be composed of the synovia or juices of the ankle or fetlock joint, which, by some of the forementioned causes, is made to flow or leak from the joint, and is at first collected into a small sack in the back part of the fetlock joint; from thence it is conveyed by two small tubes to each side of the foot, where it gradually forms the callous or ring-bone.

For the last thirty years I have been in the habit of successfully performing an operation, which prevents the ring-bone from increasing in size, and if not lame previous to the operation, the animal never after becomes lame in consequence of the ring-bone; but if lame before the operation is performed, a period of from one to twelve months is required for their recovery, much depending on the length of time which they have been lame.

The operation is performed in the following manner. I first shear off the fetlock, then make an incision thro' the skin and extract the sack above mentioned, at the same time taking care to destroy the communication from the joint to the ring-bone, by cutting off the tubes or conveyors from the joint to the ring-bone.

If the aforesaid operation is performed skilfully, the horse is as fit for use in one week as before.

ZECHARIAH CONE.

Hebron, Conn., March 26, 1838.

Remarks.—Dr. Willich says, where the tumefied part is distinctly perceivable round the pastern, without affecting the coffin joint, it is easily cured, but if the swelling be of long continuance, and has become hard, it may then require both blistering and firing," i. e. searing with a hot iron"—Extend a mild blister over the cauterized part.

Importance of Agriculture—to all.

Stroudsburg, 23d May, 1838.

Dear Sir,—Although not a farmer by occupation, yet there is no department of human industry regarded by me with so deep an interest, as that of the cultivation and melioration of the soil. The sad experience of the few last years has brought us to feel how immediately we depend upon the humble calling of the husbandman for the daily supply of our most pressing wants. Under Providence, society looks up to the farmer; who holds in trust the elements, not only of human comfort, but of existence itself. How important then is the business of agriculture—and, I will add, how respectable too. Yes, sir, how respectable, *in itself*, and in the *public estimation*. Among private citizens, I know of none more worthy of honor than the industrious, intelligent and virtuous farmer—and to such a man, notwithstanding his plain garb and hard hand of labor, I would sooner bow, than to a score of genteel loungers, who contrive to "lash the lingering moments into speed" by novel reading, hunting, fishing and the like.

But the farmer, in order that he may receive honor from those only who can confer it, must have *intelligence*, hence he must *read*, for no man in these days of improvement and experiment can keep pace with society unless he adds the experience and observation of *others* to his *own*; and this is to be done by reading, reflection and experiment. Hence the utility of well conducted agricultural journals—and such, sir, without intending flattery, I would denominate yours.

When I sat down, I intended to touch a subject on which I would be glad to see some remarks from yourself. In every district of country where I have resided, a general belief prevails of the influence of the *moon's phases* on vegetation, as well as on various other things, together with a belief in the important influence of the *signs*. Now if these influences are only imaginary, as I suppose them to be, it is a matter of some consequence that the farmer should settle that point in his own mind. If error it is, it is by no means a fruitless error. Bad consequences, at least sometimes, may follow. Take an instance. A farmer has prepared his ground for Indian corn. It is in good condition; the season has come round, and all is favorable—*except the sign*. He must wait a week, perhaps, for the sign to travel on to *aries*, in order that the ears of his anticipated crop may correspond in length with those members of the body. When at last the golden moment arrives, sad to state, a rain has set in, which, had he committed his seed to the ground in season, would have been most favorable to its early germination; but, as matters are, it may put to hazard his whole crop, in those latitudes where a week's difference in the accession of the first autumnal frost will often make the difference of harvest or no harvest.*

---

* The moon has unquestionably an influence upon vegetables and animals, as well as upon the ocean of waters; but we have never seen it attempted to be maintained, by men of scientific knowledge, nor have we ever believed, that one phase of this planet was more favorable to the deposit of seeds in the earth than another phase; and as for *signs*, the only one that we ever wait for, after our ground is prepared, and the season of planting or sowing arrived, is that of *good weather*, which we are sure to improve; and seldom fail of realizing good crops, whether the moon, at planting, be in *aries*

But I will not enlarge—leaving this subject with you, and wishing you all that success and enjoyment which labors like yours deserve, I am, with great respect,

Yours, &c. WM. P. VAIL.

Jesse Buel.

Joint-Murrain, or Garget.

Judge Buel:—A disorder has prevailed among cows in this vicinity, for the last twelve or fifteen years, which I have never seen described, and which baffles all attempts at immediate cure. It generally attacks young cows in milk, and rarely extends to any other stock.

The animal is taken suddenly lame, generally in one foot, but is soon lame in all. No local inflammation is perceptible. Slight costiveness and some fever generally attend it. On examining one recently, I found the hip bones carious to such a degree, that they might be cut with a knife. The spinal marrow was dissolved to a watery substance, in the vicinity of the diseased part. The animal had been helpless in its hind parts for a month before it was killed.—The rotten bones were broken from the spine. Frequently the disorder commences in the fore feet. I have never examined one thus taken.

Cows in high flesh are as liable to the disorder as any. In some instances, it has been cured by drying the cow immediately; in others, this remedy has failed.

Having never had any of my own cows affected with the disease, perhaps I cannot describe it so minutely as some others—the above, however, are the general characteristics. Can you, or any of your correspondents, give information as to the cause of it, or suggest a preventive or remedy? If so, you will advance the cause of agriculture in this section of the country, by giving it publicity through the columns of the Cultivator. J. K. SMITH.

Dublin, N. H. June, 1838.

Remarks.—We are not skilled in the diseases of cattle; and we are satisfied that we are suffering immense losses annually, in the death, by diseases, of our domestic animals, which might be avoided, had we schools, like those of Europe, to teach and promulgate correct knowledge in the veterinary art. Having no resource of this kind, to apply to, we avail ourselves of such authorities as we have at hand, to answer the questions of our correspondent, and invite further information from any of our readers who feel competent and willing to impart it.

Lawrence has grouped together a number of diseases, all of which, he says, indicate the same disease in different stages. These are known by the popular names of *shewt of blood—vomit of blood—blood in the back—blood in the legs or cratench—blane in the tongue, or overflow of blood—striking in or rising of the blood—higham or iron striking*—JOINT MURRAIN OR GARGET—*black quarter—quarter evil—black leg.* "All our animals," says he, "oxen, sheep and pigs, I have observed, are subject to sanguineous effusion, or overflow of the blood, on being put, when in a low and weak state, to rich or succulent keep. One termination of the disease is by a deposition of matter upon the joints, whence the term of joint garget or murrain." "This disease has swept off great numbers of yearling and two year old cattle, and become indeed endemical, in certain districts, where any such scourge was unknown, it is said, previously to the introduction of artificial grasses, with the full feeding on which, the animals become surfeited; thus the improvident use of good produces evil."

"Prevention of this malady is the only cure worth notice, because after the attack, the very nature of the case renders all remedy either uncertain, or of very little profit. even if successful, on account of the expense of time and money. With this view the young cattle must not be put so forward in condition, and indeed the same precaution may be useful, in some degree, with respect to the full aged. Those observed to advance very fast, may be bled monthly for several months, or may be purged with six drachms, daily, for a month, of equal parts of sulpher and antimony, in fine powder, OR SALT MIGHT BE OF USE. Rowelling also might be an efficacious preventive. Keep two rowels or setons open in each breast during several months. The disease having fallen on the joints, the best cure, I should apprehend, is to kill the beast, but if that will not agree, I am aware of no better method than to take him home foment his joints, and give two or three brisk mercurial purges." See Lawrence upon cattle, London 2d ed. p. 294, &c.

Prevention, we all know, is better than cure; and if we would profit by this adage, we should make the transitions from low to high feed, in our domestic animals, slow and progressive; and give them DAILY ACCESS TO SALT, a condiment as essential to health and comfort in the daily food of the brute, as it is in the daily food of man. The best authorities, and most experienced farmers, concur in the opinion, that salt is the grand preservative of health to domestic animals.—To test its value of the animal, daily, let any one take it in his food only monthly, weekly or semi-weekly, as he is accustomed to dispense it to his stock, and he will soon become a proselyte to our belief.—*Cond. Cult.*

On Summer Fallowing.

Schaghticoke, June 5*th*, 1838.

Sir—With a desire to gain information, permit me while I give my own, to ask your opinion as well as that of some of your numerous correspondents, upon the subject of summer fallows. 1st. Are they ever beneficial to the land or crop which it is intended to produce? 2d. If beneficial, are the benefits an equivalent to the enormous expense attending them? 3d. Would not a clover sod be a better preparation for wheat than the naked fallows? Satisfactory answers to these queries, I conceive to be of immense importance to your readers. Some of the agricultural writers of Great Britain, contend that the general abandonment of the naked fallow system in that kingdom, has tended more to produce the high stand which her agriculture now sustains, than every other improvement combined. If such is the fact in relation to Great Britain, why would not its abandonment in this country be attended with a like good result? Look at the immense expense in preparing our lands for wheat. Our farmers, by the course they pursue, are not only at the expense of one or two extra ploughings, but lose the use of their lands through the summer, which could be made to support an immense number of cattle, and thereby greatly augment the profits of these farmers, and increase the quantity and improve the quality of those manures, which have been rightly termed, "the magic wand that the farmer uses," and upon the production and just application of which not only depends our immediate interests, but the high reputation which we hope ere long to see our agriculture sustain. "Nature seems to require no rest, and the earth was evidently designed to produce a constant uninterrupted vegetation." If then the productive quality of the earth never ceases, why should this principle of nature be perverted, and our lands laid bare and exposed to evaporation, instead of being covered and protected. One argument often produced in favor of the fallow system is, that it cleans the land from weeds. Tull, in speaking of the British fallows, said, they presented nothing but a conflict between the farmer and his weeds, in which the latter generally prevailed. Our lands well laid down in grass, are free from weeds, and why are they not in as good a condition to receive a crop with one good ploughing as a half a dozen? It is a fact incontrovertible, that the decomposition of vegetable matter produces food for plants.—By summer fallowing, the vegetable matter is all decomposed and evaporated before the crop is put upon the land. The old school of farmers tell us that the sod should be well rotted before the soil is fit to receive the seed. This idea appears as absurd to me as that straw should be reduced to a powder before we apply it to our soils. The general practice which has been pursued upon the wheat farms in this county, is to sow wheat every other year after summer fallow, until the occupants found that their lands would no longer produce wheat. It would have been millions in their pockets had they pursued an alternative system, and known that it was the fallow, not the wheat, that so soon exhausted their lands.—Wheat farms should be made stock farms. Every farm of 200 acres, by alternating wheat and clover, and cultivating a few acres of roots, can be made to support more stock than 100 acres upon which a plough is never used, as the straw would help to winter them, and with the increased quantity of manure, their crops would, in a few years, be doubled, and the soil continually enriched. I have been perfectly successful in raising wheat upon a clover sod; and so fully am I convinced of the bad effects of summer fallows, that unless this mistaken kindness towards the wheat crop can be abandoned, I believe it would be a benefit to this country should the wheat insect spread over every part of it, and leave us dependant upon the eastern world for this part of our bread stuffs. Yours, with respect,

J. C. MATHER.

Remarks.—The reasoning of our correspondent is sound, and its correctness is verified by results of all who have given a fair trial to fallow crops, as a substitute for summer fallows. The only cases, in our opinion, where naked fallows should be tolerated, that is repeated summer ploughings given for a wheat or rye crop, is where the soil is a stiff wet clay, which will not grow clover, and lands which abound in fibrous, woody matter, when first reclaimed by draining. Good draining, and especially what is termed furrow draining, will supersede the necessity of summer fallowing wet and stiff clays, and vastly improve the texture and productiveness of the soil. If such grounds are ploughed in narrow ridges in autumn, and the furrows well cleaned, that the surplus water may pass off, they may be sown with oats early in the spring, and be in fine condition for winter grain in September. The difference in profit between the two modes of converting sward into wheat, may be stated thus: The three ploughings and harrowings for summer fallow, may be estimated at $8, and the use of the land is virtually lost for the season. In the other mode two ploughings suffice, for the oat and wheat crop, thus saving at least $2.50 of the outlay—while the oat crop, if any way tolerable, will make a return of twelve or fifteen dollars additional. The land will be richer, and in better condition for wheat, because it will retain the vegetable matter of the sod, than if it is summer fallowed. The fertilizing matter of the sward is exposed and wasted by the cross ploughings. To render a fallow a cleaning process, it is customary, in Britain, to pick and gather, after the harrowings, the perrennial roots and quack-grass, and to burn, or mix them with the dung—a labor which our farmers seldom or ever incur.—*Cond. Cult.*

EXTRACTS.

Character of Dutton Corn.

We copy the two following articles from the Hartford Times, at the request of a respectable correspondent.

Mr. Editor—An article has been copied in several papers from the Springfield Republican, commending in the highest terms the *Dutton or Canadian corn.*—Had not the writer of this article been explicit in his statements, giving names, dates, &c., the agricultural portion of the community would have considered it a gross imposition. We saw the article advertised last spring, perhaps in your paper, as peculiarly adapted to this cold region, sure to ripen three weeks earlier than the "old fashioned" corn, &c.

In common with many of my neighbors, I repaired immediately to the advertiser, bag in hand, and as a special favor, at the rate of *four dollars* per bushel, obtained a few quarts. Our children and friends looked at it as one of the great discoveries of modern times, and it was no effort of our imagination to see the fruits of it early in store, long before the appearance of autumnal frosts. I planted it on the 18th of May, in my garden, and at the same time, and adjoining, planted an equal quantity of the "old fashioned" corn. As the ordinary time arrived for family use, I looked, but looked in vain, for the ripening of the Dutton corn. My faith, however, did not fail, until the 4th of October, when, after the old fashioned corn had been ripe more than two weeks, this *celebrated* corn was in the milk, hardly ripe enough to roast. The frosts came about this time and destroyed it, and with it all my confidence in Dutton corn.

Now, sir, if this was the result of my experience alone, there might, perhaps, be some question as to the fairness of the experiment. But since reading the article alluded to, I have conversed with at least six of my neighbors, whose experiments and opinions on this point correspond with my own. If necessary, we are willing to give our names, and think it our duty to express our opinion, that, as regards this section of country, at least, it is an imposition to recommend it. It may seem a slight matter to the "soft handed," who labor by proxy, but to those of us who earn our bread by the "sweat of our brow," it is not only a serious loss thus to plant and not to reap, but it is exceedingly mortifying and provoking.

For a time we thought of prosecuting the advertiser, but we consoled ourselves with the idea that as "monsters cannot beget their own species," no more seed of this kind would very soon be offered to the public.

A LITCHFIELD COUNTY FARMER.

Mr. Editor,—In your paper of the 12th inst. I noticed an article signed "A Litchfield County Farmer," giving a somewhat ludicrous account of his experiment, and of those of six others of his neighbors, in planting and *attempting* to raise that variety of Indian corn now known by the name of the Dutton corn.

It is to be regretted that when gentlemen undertake to place before the public any statements, respecting their own experiments in agriculture, by which any benefit may be expected to result for the common interest, that they withhold their names from the publication of facts, on which their opinions are formed, and their conclusions drawn—leaving the reading part of community at a loss what degree of credit ought to be attached to such anonymous statements.

That frauds and impositions have been practised by certain persons, in selling seed corn under the name of Dutton corn, is well known; but these very frauds go to establish the truth of the fact that this variety has acquired a distinguished reputation, after several years trial by the most experienced farmers in our section of the country, and of course greatly raised the price of this seed—witness the "few quarts" bought by the "Litchfield County Farmer at the rate of *four dollars* per bushel."

I have, Mr. Editor, no other interest in this subject than that of an ordinary farmer in raising corn for my own use. Such have been our seasons for several years past, that I, with many others, have been solicitous to obtain a variety of that useful article which should arrive at maturity as early as might be, to avoid injury by our autumnal frosts. In these endeavors I have succeeded beyond my expectations. I will now state the facts.

In the spring of 1837, I bought of Mr. St. John, of Hartford, a small quantity of the Dutton corn for seed. On the 28th and 29th days of April, I planted in one field sixteen acres—eight of which with the seed of the Dutton, and the other eight with the seed of the common yellow, or, as is denominated by the "Litchfield County Farmer," *the old fashioned corn.* The land throughout was of the same quality, and had the same tilth and culture. The Dutton was fully ripe and fit for

---

or *pisces*—in the ram or the fish. The superstitions you mention belong to a by-gone age, when seeing the new moon over the *left* shoulder was deemed an infallible sign of ill luck.

harvesting 16 or 18 days before that of the common yellow—not an unripe ear, nor any mixture of refuse, or what is commonly called *pig corn*, was found among it—whereas among the eight acres of the common yellow, one-third part of the whole was, by reason of its immaturity, thrown by as *nubbings* and *pig corn*, wholly unfit for market. I carefully measured in a half bushel one hundred of ears of the Dutton corn and shelled it. The quantity of the shelled corn was half a bushel and three pints—the weight of the half bushel was thirty-four pounds. Those of my neighbors who planted the same kind of seed the last season, experienced much the same results.

I have now to propose to the "Litchfield County Farmer," that if he will take the trouble to honor me with a visit, I will give him "a few quarts" of the *true* Dutton corn, and let him plant it on the same kind of land as that on which he plants his "old fashioned corn" and give it the same husbandry—if the Dutton corn does not come to maturity at least 14 days earlier than the other, I will pay him for the time spent on the journey two dollars per day, and keep him at my house free of expense to him.

I have now only to add, by way of statement, that, from careful observation, I am prepared to say, that, supposing the season to have been such as to have brought the eight acres of the *common yellow* to maturity without any injury by frost, the quantity would have been one-third less than on the other eight acres.

In conclusion, I think it cannot admit of doubt, that the "Litchfield County Farmer" was imposed upon in the "few quarts" of seed purchased by him. His doleful story of the disappointment of himself, his "children and friends," in their raised expectations of the luxury of the Dutton corn, reminds me of an historical incident, not altogether unlike in its character to the case of our "Litchfield County Farmer."

At an early period of the fur trade between the Hollanders and the western Indians of our country, the Dutchmen bartered off at an enormous price a quantity of their gun powder for beaver. At the close of the trade for the season, when the pale faces were about to return, they informed the Indians that they had a small quantity of *gun powder seed*, which they would sell, in case they could receive a price adequate to its immense value—assuring the red skins that by careful planting and good cultivation, they would be enabled in future to raise their own gun powder. The bait was greedily swallowed, and the purchase made by large piles of beaver skins. The Dutchmen soon took themselves off. The Indians prepared their ground and sowed the seed agreeably to the directions given. After waiting a long time for the expected vegetation of the seed, they examined the ground by digging down, and the trick was discovered.

The purchasers, with their *papooses and friends*, were overwhelmed with disappointment and chagrin, greater, perhaps, than have been endured by the "children and friends" of the "Litchfield County Farmer."

East Granby, May 18, 1838. HORACE CLARK.

Books on Agriculture, for School Boys.

We have thought the cause of agricultural improvement would be greatly promoted by the publication of a series of elementary books on agriculture, designed for the use of the schoolboy. Why should not our children have facilities for the acquisition of knowledge applicable to this pursuit as well as on less useful ones? If education is designed to fit us to engage in the practical duties of life; why is it that the most important of all earthy subjects, and one which occupies the labors of a vast majority of our people, is not the leading object of the schoolboy's education? We have elementary books on every other subject; we have schools wherein are taught the rudiments of every science, schools of law, medicine, divinity, of fighting, dancing, and of every thing but of agriculture. There is something wrong in the national practice on this subject. We ought to give to the most important subjects the highest degree of attention—we must graduate various branches of education by the standard of their relative importance, and give to those having the nearest relation to our most important interests, the greatest share of favor. We ought to have the principles of husbandry taught in every common school and a chair of agriculture endowed in every college. And we think the first step to the introduction of this new branch of education is, to have the necessary elementary school books. We have many men in our country, eminently capable of compiling such works and adapting them precisely to the capacity of the schoolboy.—And he who would prepare a set of works on agriculture for the use of schools, such as would give to the boys of the country destined for the pursuits of husbandry, a thorough knowledge of the principles and the outlines of the practice of agriculture, would do more for the general good and for his own literary fame, than in any other walk of science or learning. Let it not be supposed that we decry other branches of science or learning. We are in favor of all; and especially those which contribute useful aids in the practical labors of life. We would render all subservient to man's use; and it is only in this view that they should be appreciated. But it is admitted on all hands, that agriculture is the most universal, the most dignified, the most congenial, virtuous and productive pursuit of mankind—the substratum of all other pursuits—the life and soul of commerce and manufactures—the mother of the arts and sciences—the basis of civilization; and we insist, it is *not* seeking too much when we seek to give to her own child, the husbandman, a higher grade of education. Whatever description of knowledge, relates nearly or remotely, to the multifarious labors of the agriculturist, should be an object of his study, and constitute a portion of his exercises at the primary school and the college, and employ his reflections in all the riper years of after life. One of the most absurd and mischievous errors of the day, is that of the father, who gives to the son destined for a farmer an education inferior to that he bestows upon the one destined for a profession. The husbandman deserves a better education than a lawyer or a doctor; because his occupation requires the exercise of more knowledge; but it is too generally the case, that he is only allowed some snatched intervals between the crops, "to learn to read, write and cipher"—and this is deemed education enough for a farmer! O, what a wretched, miserable error is this—what a foe to the improvement and dignity of the class! It ought, it must be banished, and the practice which results from it abolished, and a wiser and better one substituted. Now, however the remark may seem to censure the general opinion and practice on this subject, and although we may be even ridiculed by many farmers themselves, for the apparent ultraism of the sentiment, we are bold to declare, nevertheless, that the farmer *has need* of a better education, and he actually more often requires the aid of more various branches of science in his ramified operations, than the member of *any* profession; and we sincerely believe, that if any discrimination should be made in the education of two sons, one destined for a farmer and the other for a profession, it should be in favor of the former. Let us not be misunderstood—the boy destined for a profession or trade should be thoroughly educated in all branches pertaining to his distinct calling; while the boy intended for a farmer should be thoroughly instructed in all the principles to which the intelligent and scientific agriculturist stands indebted for the successful result of his labors. We could easily show, that these principles are drawn from a wider range of sciences than are necessary to be consulted by one destined for any of the so-styled *learned* professions; and consequently it would be shown that the husbandman needs a more extended education. A young man preparing for the bar is ready to enter upon his legal studies on attaining some smattering of Latin, (or it may be Greek); and many do not even go thus far before taking up Blackstone. A short course of reading elementary works on the principles and practice of law, and the student enters on the practical field of his profession. The physician requires more preparation to qualify him for practice. He too, learns the dead languages, and studies the principles and practice of his art, but those principles involve a knowledge of various abstract sciences, and he is constrained to invoke the aid of anatomy, physiology, chemistry, mineralogy, botany, &c. &c. before he enters upon the practice of his profession. We are speaking of those studies only as they relate to the *professional* qualifications of the student, and of course we are not to be understood as denying either the possession or the importance of other branches of learning to professional men. They, as well as agriculturists and others, in their social and political relations to community, are equally required to discharge the duties of *citizens;* and we hold that all classes should avail themselves of every accomplishment which learning or science can bestow, in aid of the performance of those high duties. But we need not array comparisons or illustrations on the subject: our opinions may be presented at one view. We would give to every one, of whatever pursuit, precisely the education adapted to it—and it should be thorough and perfect in all its branches, or at least so far as any or all the branches related to the peculiar pursuit adopted by the student. It should thus qualify him for the intelligent prosecution of the labors of his life and ensure his complete success. It would render the farmer as illustrious, and certainly as useful, in his sphere, as the profoundest statesman or professor. But the subject is too interesting to be treated satisfactorily in the narrow limits to which we are circumscribed; and we mean to pursue it.—In the meantime, we submit to the board of education, and to the commissioners of common schools, the propriety of early considering the importance of adopting a series of agricultural works, as text books in the schools about to be put in operation under the excellent common school law of the state. They may do incalculable good to the children of Kentucky, which will flow to other generations, and they may render the system far more useful and effective, by seasonably directing their earnest attention to the subject.—*Frankfort, Ky. Farmer.*

Quality of Milk during the process of Milking.—Several large coffee-cups having been successively filled from one cow, till she was quite dry, the following results appeared: great care being taken to weigh the cups to ascertain that they held exactly the same quantity: In every case the quantity of cream was found to increase in proportion as the process of milking advanced. In different cows the proportion varied, but in the greater number the excess of cream in the last cup, as compared with the first, was sixteen to one—in some it was not so considerable:—therefore, as an average, it may be called as ten to twelve to one. The difference in the quality of the two sorts of cream was no less striking: the cream given by the first drawn milk was thin, white, and without consistence, while that furnished by the last was thick, buttery, and of a rich color. The milk remaining in the different cups presented similar differences: that which was drawn first was very poor, blue, and had the appearance of milk and water: that in the last cup was of a yellowish hue, rich, and to the eye and taste, resembled cream rather than milk. It appears, therefore, from these experiments, that if after drawing seven or eight pints from a cow, half a pint remains in the teats, not only almost as much cream will be lost as the seven or eight pints will furnish, but that of the best quality, and which gives the richest taste and color to butter. This fact has been corroborated by chemical experiments, and holds good with respect to goats and asses.—*Blachler's Essay on the Improvement of small Farms.*

[*From the Farmers' Magazine.*]

Old and New Husbandry.

Sir—Glad that my former observations have interested your readers, I am now desirous, with your permission, of further prosecuting my original object, which was to encourage the employment of the poor by the occupiers of land. To this end I wish to explain somewhat more fully the means by which I am enabled to employ nearly half as many more men as are usually employed on the same number of acres, not only, as I think, without loss, but with a fair return of profit.

It may be proper to premise that my farm consists of about 200 acres; comprising 30 of wood, 42 of pasture, the rest arable. Of the arable, 85 acres are of good mixed soil, well adapted to turnips and barley, but not considered equal in value to the best wheat land; the remainder consists partly of a hungry gravel, partly of clay, of very inferior quality.—It is cultivated on the Norfolk, or four-course system.

1. I diligently collect litter of every kind, seaweed, furze, fern, leaves of trees, &c. for bedding my yards, in addition to the straw grown on the land.—In the last 12 months I have brought in about 50 wagon loads of this description; each wagon load gives employment to about three men for a day, the total is therefore 150 days.

2. This increase of litter would avail little or nothing if I did not keep an extra number of live stock, for I observe that many farmers do not even make their straw into good muck. I therefore fat about 40 hogs and four or five head of horned cattle every winter; enough, in short, to consume half my Swedish turnips, which are drawn and carried into the yards for this purpose. The drawing, topping, and carting, together with the time occupied in looking after the stock, may be estimated at one man's employment during the winter months, equal to 150 days.

3. The removal of one-half the turnips would injure the succeeding barley crop, if I did not lay on, at the time of sowing the turnips, an extra quantity of manure, say 25 single horse cart loads per acre, about 10 loads more than the usual allowance. This I am enabled to do, partly by the great quantity of litter in my yards, partly by placing a bottom of earth or chalk under every dung heap, and a thin covering of the same materials over the top. The practice of carting all my dung twice, first from the yards to bottoms prepared in the fields, and then on the land when wanted for use, of course employs many hands, as well as the turning their composts, and mixing the materials together. I believe I do not over rate the number of cart loads filled annually on my farm at 2,400, whereas on the same number of acres, a farmer who moved his dung only once, carrying it immediately from the yard, and at the rate of 10 loads per acre for turnips, the same for wheat, would fill only 600 cart loads annually. The extra 1,800 loads may give about 112 days employment, and the turning of the compost about 20 more; making together 132 days.

4. I have introduced this year the Norfolk practice of dibbling wheat. This occupies two men and six children for 30 days, at the rate of half an acre per man per day. Computing the six children equal to one man, the dibbling gives extra employment of 90 days. The expense is paid in the saving of seed, to say nothing of the increased produce, which is estimated by the best Norfolk farmers at a sack per acre.

5. Extra weeding, throwing ditches, draining, &c. may occupy about 80 days.

Let us now recapitulate—

Collecting litter, ...	150 days.
Feeding stock in yards, ...	150
Carting earth and dung,........	132
Dibbling wheat,...............	90
Extra weeding, draining, &c....	80
Total,..............	602

At 300 working days in the year, this is equal to two laborers extra, winter and summer, employed on a farm containing only about 120 acres of arable land.

It is not easy to estimate with precision the increased amount of produce which a farmer may expect to obtain in consequence of such an increased outlay in labor; the less so as that increased produce does not make itself felt the first, second, or third year, to the full extent; indeed, I have heard an intelligent farmer say, that he has observed a progressive improvement in his land during no less than *twenty* years, from persisting in a system of high cultivation. I quoted in a former letter the estimate of Von Thaer, which, however, was so disfigured in the printing (owing, I fear, to the badness of my hand writing,) as to be almost unintelligible; I beg leave, therefore, to repeat the statement.

On a farm on 913 *acres of good barley land.*

	Under the old system two crops and a fallow.	Under the improved or alternate system.
Produce in cattle, ...	£210	£1,249
Produce in grain,......	894	2,030
Gross produce,........	1,104	3,279
Expenses of cultivation,	537	1,051
Nett produce,.........	567	2,228

The last line comprises rent, profit, interest on capital, tithes and taxes of any description, the object being simply to show the *comparative* results of the two systems of cultivation. The system is not founded on speculative views, but on extensive and accurate observation during a long series of years by a man well acquainted with the practical business of agriculture. Indeed, I may observe in passing, that there is no work in the English language to be compared with Von Thaer's, so far as my knowledge extends. I am not surprised at the low estimation of works on agriculture among practical farmers. Instead of containing, as they ought to do, a digest of all that is necessary to be known by a single competent hand, such works consist, for the most part, of loose collections of suggestions, speculations, experiments, and observations; correct and incorrect, authenticated and unauthenticated; thrown together apparently almost at random, without order or discrimination.

It will be seen, on comparing Von Thaer's numbers, that his estimate of the expenses and produce on the two systems of cultivation respectively is in round numbers as follows:—On the improved system the expense of cultivation is *double;* the gross produce is *triple;* the nett produce is *quadruple.*

This statement, however, being expressed in so general and abstract a form, and resting as it does on the authority of an unknown author, is not likely, I fear, to weigh much with the majority of farmers.—Let me then endeavor to bring the question home to them by a statement of a different kind. I suppose it will hardly be disputed that by means of the system of high cultivation which I have described, a cultivator may expect to get per acre at least one sack* of wheat, one of barley, a quarter of a ton of clover, hay, and three tons of turnips additional. Let us compute the value of these items.

4 bushels of wheat at 56s...	£1 8 0	
4 bushels of barley at 30s...	0 15 0	
¼ ton of hay at 3l..........	0 15 0	
3 tons of turnips at 5s......	0 15 0	
4	£3 13 0	
Average per acre,....	0 18 3	
This on 120 acres amounts to		£109 10 0
The labor of the extra hands through the piece at 11s. per week, amounts to....	£57 4 0	
I charge nothing for horse labor, since the carting of dung, litter, &c., is performed at times when the team would otherwise be standing still. But as there is some additional wear and tear of carts and wagons, let us estimate this at	10 0 0	
		67 4 0
Extra profit arising to the occupier,....		£32 6 0

The result of this computation, if correct, ought surely to encourage every farmer to be liberal in his expenditure in the article of labor, and if not correct I hope some one of your many correspondents will point out where I am wrong. The actual produce of the present year, in my own case, is as follows:—my wheat, so far as yet threshed, averages from nine to twelve sacks per acre; the last is the produce of a new variety, which proves very prolific. My barley has yielded on an average twelve sacks per acre. I have, however, one field of barley not yet threshed, from which I do not expect to get more than nine sacks per acre, the soil being a poor gravel. The general character of the land I have already described.

I hope these statements and calculations will call forth the observations of some of your able correspondents, in order that my conclusions may be confirmed, if well founded, or corrected, if erroneous; and should they prove sound, as I am willing to believe, I trust they will contribute to promote the more general employment of the poor.

A HAMPSHIRE AGRICULTURIST.

Feb. 8, 1838.

[*From Hitchcock's Re-Examination of the Geology of Mass.*]

Theory of the action of Lime on Soils, Manure, and Vegetation.

The action of lime is threefold; each distinct. 1. It is a *Neutralizer:* 2. a *Decomposer:* 3. a *Converter.* 1. I have already alluded to some acid soils: free phosphoric acid, geic, acetic, and malic acids, also occasionally exist in a free state in soils. Here lime acts as a neutralizer. 2. Soils may contain abundant geates; particularly geate of alumina, the least of all demanded by plants. Long formed and sun-baked, they are scarcely acted on by rain or dew, and are almost useless. Here lime, by decomposing these metallic and earthy geates, forms a combination, which, in its nascent state, is readily dissolved. If the carbonate of lime acts better than the hydrate, it is because, following a well known law, double decomposition is easier than single. If any acid geine exists in the soil, or any free acids, carbonic acid is then liberated; it acts on the geate of lime, supergeates result, and these are easily soluble.

3. The great use of lime is as a *converter;* turning solid and insoluble, nay, I go further, solid vegetable fibre, into soluble vegetable food. Here is the great puzzle, the point where our philosophy seems to leave us; giving us our choice, to refer this action to one of the numerous cases of mysterious '*catalytic*' change, with which we are becoming every day more and more familiar, or to explain the process by referring the whole to *saponification.* I use this word as conveying to you at once what I mean;—but I do not mean to say that the product of lime and vegetable matter is soap; but I cannot make myself more intelligible to a farmer than by saying, this lime makes compounds of vegetable matter, just as it makes soapy compounds of oil and fat. The action of lime on geine I take to be of the same nature, as its action on oils and fat.—It is well established that animal and vegetable oils and fats are converted into acids by the action of alkalies, earths, oxides, and even by vegetable fibre itself. The general law is, that whenever a substance, capable of uniting with the acid of fat or oil, is placed in contact with fat or oil, it determines the production of acid. Now we have seen that alkali produces a similar change on geine; it develops acid properties. I go further, if alkali has converted vegetable oil and geine into acids, I see no reason why a similar action may not be produced by all those substances which act thus on oil. Hence *lime,* earths, and metallic oxides, convert geine into acid: as fast as this takes place, so fast it becomes soluble. Then too the long action of air on insoluble geine, rendering it soluble, is it not analogous to the action of air on oils?—Both evolve in this case, vast volumes of carbonic acid, the oil becomes gelatinous and soluble in alkali; does not a similar change occur in geine? It is possible that during the action of lime on geine, a soluble substance may be produced, bearing the same relation to this process that glycerine does to saponification. These views you will see need to be followed out experimentally. If found tenable, the most signal benefit will result. We place manures on a new foundation, on which great practical results may be erected.

Practical application of the theory of the action of lime.

Taking the preceding principles as our guide, we may lay down a few general principles for the application of marls.

1. Enough ought to be applied to neutralize all the free acids in a soil; which may be known by its ceasing to produce acid plants, such as sorrel and pine.—Generally, however, the amount required for this purpose is small.

2. It will be serviceable to add enough to convert the earthy geates of a soil into geate of lime. The richer a soil is, the greater we may conclude is the quantity of geates which it contains.

3. It will be serviceable to add enough to convert all the insoluble geine and vegetable fibre in a soil into soluble geine. Hence the richer a soil is, and the more manure is added, the more marl will it bear with benefit. Indeed, *there appears to be no danger of adding too much marl, provided a sufficient quantity of manure be also added.* Ignorance of this principle, I apprehend, is the source of most of the failures that have occurred in the use of lime upon soils. Farmers have supposed that its action was like that of common manure, viz. to serve as direct nourishment to the plant; whereas it only *cooks the food,* if I may be allowed the expression, which exists in the soil, or is added along with the lime. In nearly all cases of over marling which I have read of, a fresh supply of manure has been found to be the remedy; which shows the truth of the above principle. Agriculturalists have spread marl alone, or with very little manure, upon land that has been worn out, that is, whose geine has been exhausted; and because such soils have not thereby been recruited, they have inferred that lime was injurious. Without acids, or geine, or geates, or vegetable fibre, to act upon, much excess of lime appears to operate injuriously, so as to diminish, instead of increasing the crop. They have also expected a sudden and surprising increase of fertility: whereas in some cases the chief benefit seems to consist in causing the land to produce for a greater number of years, by preventing the ultimate decomposition and escape of the organic matter. In general, however, it will add also to the yearly product: but those who employ marl or lime in any form, ought to moderate their expectations that they may not be disappointed, and to be satisfied if they can slowly and surely improve their lands, as they most assuredly can do, by this substance, provided they do not expect to accomplish it by the use of lime alone.

Templemoyle Agricultural School.

The Agricultural Seminary of Templemoyle originated at a very numerous meeting of the North-west of Ireland Farming Society at Londonderry, and it was at first intended that it should consist of two establishments, taking Mons. Fellenberg's Institution at Hoffwyll in Switzerland in some degree as the model: the first to be a school affording instruction in every science and accomplishment aimed at by the children of the higher orders; the second for the education of the sons of respectable farmers and tradesmen, in the hope of disseminating the advantages of an improved system of farming with greater certainty, by combining the practice and theory of it in the instruction of those who were afterwards to make agriculture their pursuit. It was hoped that the extended scale of the institution would have allowed of a greater variety of masters and lecturers, and that the profit derived from the superior school would have contributed towards the maintenance of the secondary one; but a short experience convinced the subscribers that such a scheme was impracticable without much larger and more certain funds than they could rely on; they then gave their undivided attention to the agricultural seminary, which through their increasing exertion has attained such eminence as may justly entitle them to look forward with confidence to its increasing usefulness, and to its becoming a model for establishments of a similar nature in other parts of Ireland.

The school and farm of Templemoyle are situated about six miles from Londonderry; about a mile distant from the mail-coach road leading from Londonderry to Newtowlimavady. The house, placed on an eminence, commands an extensive and beautiful view over a rich and highly cultivated country, terminated by Lough Foyle. The base of the hill is occupied by a kitchen and ornamental garden, cultivated by the youths of the establishment, under an experienced gardener. The ground between the garden and house is laid out in beds in which all the different grasses, clovers, &c., are cultivated with the greatest care. The house is in the form an ||═||, with range of farming offices behind, containing spacious, lofty and well ventilated school rooms, refectory, dormitories, apartments for the masters, matron, servants, &c.

Each pupil occupies a separate bed; the house can accomodate seventy-six, and the number of pupils amounts to sixty. They receive an excellent education in reading, writing, and arithmetic; book-keeping, mathematics, land-surveying, and geography. This department is managed by an excellent head master and assistant master, both resident in the house. The pupils are so classed that one-half are receiving their education in the house, while the remainder are engaged in the cultivation of a farm of 130 Cunningham or 165 statute acres, in the management of which they are directed by the head farmer, an experienced and clever man, a native of Scotland, who has a skilful ploughman under him. The pupils who are employed one part of the day on the farm, are replaced by those in the school, so that the education always advances in and out of doors *pari passu.*

---

* A sack is four bushels.

The pupils are thus instructed in all the practical parts of farming, and are also several times a week on the theory of agriculture. They are made acquainted with all the properties of different soils, the manures most applicable, and the crops best adapted to each; points in which most of our practical farmers displayed great ignorance. They are also made acquainted with all the numerous varieties of cattle, and their qualities, such as early maturity in some breeds, hardihood in others, and have strongly impressed on them that one of the most essential points in farming, is to select the cattle and the crops best adapted to the situation, soil, &c.

The stables, harness-rooms, cow-houses, winter-feeding houses, piggeries, barn, tool-houses, are arranged in the best manner, and the pupils are required to keep them and their contents in the highest order. A respectable and intelligent matron has the superintendence of the dairy, cooking, and cleaning the house, and the charge of the domestic servants.

In sending a pupil to Templemoyle, it is necessary to have a nomination from one of the shareholders, or from a subscriber of 2*l.* annually. The annual payment for pupils is 10*l.* a year; and for this trifling sum they are found in board, lodging, and washing, and are educated so as to fit them for land-stewards, directing agents, practical farmers, surveyors, schoolmasters, or clerks.

From fifteen to seventeen is the age best suited for entrance at Templemoyle, as three years are quite sufficient to qualify a student possessed of ordinary talents and a knowledge of the rudiments of reading and writing, to occupy any of the above situations.

N. B.—Upwards of two hundred young men, natives of sixteen different counties in Ireland, have passed through or remain in the school. Of these between forty and fifty have been placed in different situations, such as land-stewards, agents, schoolmasters and clerks, or employed on the ordnance survey. Nearly one hundred are now conducting their own or their fathers' farms in a manner very superior to that of olden time; and the accounts of those who have been placed from the seminary are such as to gratify the gentlemen who have its interest at heart, and to convince them that the good seed sown is producing an ample and valuable harvest.

Templemoyle, Oct. 14, 1837.

[It gives us unqualified pleasure to lay before our readers the above gratifying account of an institution so eminently calculated to confer lasting benefits upon the country. We have been long strenuous advocates for the establishment of agricultural schools in all parts of Ireland, feeling assured that they would ultimately be the means of breaking down those absurd prejudices which have been hitherto the most insurmountable obstacles with which agricultural improvement had to contend.]—*Editors [British] Farmers' Magazine.*

Decomposition or Putrefaction of Vegetables.

All vegetables, when the principle of life has departed from them, begin spontaneously to be decomposed (to putrify). The elements which enter into the composition of plants, when left entirely to the disposal of their chemical affinities, have a tendency so separate from each other, and form new compounds very different from those which compose the living plant. This is termed the "spontaneous decomposition" of vegetables. The substances formed by the new arrangement of the elements of the vegetable are aerial and colourless;—hence the entire disappearance of the vegetable, as if it had been totally annihilated when life ceased to preserve its particles together in the vegetable form.

The compounds formed, when the vegetable dies and putrefaction goes on, are, carbonic acid, water, carbonic oxide, and carburetted hydrogen. The two former are the chief results of the decomposition; the two latter formed more sparingly, and principally when there is not a free supply of oxygen to the substance undergoing decomposition. The carbon and hydrogen of the plant have a constant tendency to unite with oxygen, and form carbonic acid and water. Now there is never present in the vegetable a sufficient supply of oxygen to convert all the carbon into carbonic acid, and all the hydrogen into water; hence, if there be not a sufficient supply of oxygen to produce these compounds presented from external sources, as from the air, the two other matters are formed, one of which (carbonic oxide) requires a less quantity of carbon than the carbonic acid, while the other (carburetted hydrogen) requires no oxygen, consisting of carbon and hydrogen.

In vegetables which decay under water, caburetted hydrogen is abundantly formed; hence arises the gas which is found so plentiful in summer in stagnant waters containing quantities of putrefying vegetables.

The spontaneous decomposition of vegetables goes on most rapidly when they are exposed to the air, kept moist, and preserved at a degree of warmth higher than the usual temperature of the atmosphere. Putrefaction is retarded or almost prevented if the vegetable be dried, so that its own moisture is expelled, carefully excluded from air and moisture, and kept cold. The influence of heat in promoting the decay of vegetables depends upon the repulsive power it possesses, by which it disposes the various elements to assume the gaseous form. Animals and vegetables are frequently found in snow or ice, in a high state of preservation.

Such are the changes which go on in the dead plant. That mysterious agent, Life, is able by its peculiar power, to control and overcome the chemical attractions which tend to produce these changes, and retains these elements in that state of combination best adapted for the performance of their proper functions: at the moment however, in which life ceases to superintend the exercise of these functions, they cease and the chemical attractions, no longer restrained by the vital principle, obtain full sway. The carbon, oxygen, and hydrogen, formerly existing in the state of wood, bark, leaves, fruit, or seeds, obey the laws of chemistry, return to the state of carbonic acid; water or inflammable gas mix with the earth and atmosphere, afford nutriment to new plants, again form leaves, flowers, and all the beautiful and diversified organs of the vegetable creation—again wither and decay, and return to the soil to supply new generations, and continue the same series of unceasing revolutions.—*Chemistry of Nature.*

Application of Marl.

On reading the last No. of the Cabinet I perceive that your readers in the lower part of Delaware and the Eartern shore of Maryland, where the green sand or marl abounds, are desirous of being informed of the best mode of applying it as indicated by the experience of our New-Jersey farmers. It may perhaps save those who are inclined to try it, some trouble and expense to be informed that every known method of application seems to have been resorted to; and that which has been found to answer best, is to use it as a top dressing on sward or grass grounds; the effect is immediate and great, being scarcely to be believed excepting by those who have been spectators of its effects. The quantity applied to an acre of good marl is from six to twenty tons; a bushel weighs about a hundred weight—of course a ton is about twenty bushels; more may be applied without any apprehension of injury, but from twelve to fifteen tons per acre is a good dressing, though some have applied twice that quantity. Spread it evenly over the surface of the grass ground in the fall, winter or spring, or whenever you have most leisure, and when done you need not give yourself any further trouble about it; nature will do the rest, and your reward will be certain and great if your marl be good. Whenever you plough down your grass ground which has been thus marled for corn, or any other crop, you will see the effect of it strikingly exhibited in the subsequent crops. It has frequently increased the fertility of the soil more than ten fold, and some crops are believed to be much improved in quality as well as quantity by its application.

The great weight of the marl causes it to sink in the earth, and if it should be ploughed in on its first application, there is some danger of losing part of the good effects of it, by its being placed too remote from the roots of the plants intended to be nourished by it.

It is now agreed on by all, that the fertilizing ingredient of this valuable substance is potash, and the benefits derived from its use are directly proportioned to the quantity of it contained in its composition.—*Communicated for the Farmers' Cabinet.*

Notice of an Experimental Farm in France.

BY COL. LE COUTEUR.

It is situated, in a beautiful and fertile country, well wooded and watered, but cultivated by the Breton farmers just as their fathers tilled it 200 years since. The college or experimental farm appears like a garden in a smiling wilderness, so far as culture goes. I rose at four in the morning, in order to witness the whole course of labor in this interesting institution.

There were from 80 to 90 students under the superintendence and tuition of a director, a professor of agriculture and agricultural chemistry, a veterinary surgeon, and an agricultural implement maker. At half past four they took a slight repast, and as the clock struck five, all were employed; some in harnessing the horses and oxen, others in carting out and properly disposing the implements in the field, others set to hoeing, others weeding, some ploughing, some hay making, in a word to all the various labors of the season.

The school is divided into working parties of ten; at the head of each is a steady young man of experience, called the 'decurion,' who directs the work of his party. In all difficult operations, a regular farming laborer is at hand to perform them; but such is the ardor and perseverance of the youths, that they rarely allow any difficulty to arrest their progress. The duty of one 'decury' or ten, is to dress, litter and feed the cattle, with as much regularity as a cavalry corps dress their horses; also to keep the farm-yard in order. Thus all, in turn, are made acquainted with every thing connected with a farm, whether in regard to horses, oxen, cows, pigs, or manures. These last are made and husbanded with the greatest care, the mixons being formed of sweepings, leaves, and weeds that had not seeded, in alternate layers with stable manure.

The drainings of the stables and straw-yard, run into a tank, to be pumped out when required as liquid manure, which is in the best, most portable, but least known in this country.

The learned professor M. Donku, who is an admirable practical farmer, as polite and communicative as he is learned, complained that he had not a sufficient quantity of manure. I urged him to burn the underwood and decaying timber of the large adjacent forests, through which wide roads were cut, which would enable him to obtain an inexhaustible supply of ashes the best of all manures either for turnips or wheat; the cartage of ashes being easy, and the quantity required to dress the land not being great; in which he entirely coincided.

At nine all come into their studies, when they write remarks on the various operations of the morning. From eleven to twelve is the breakfast hour. From twelve to three is the time for recreation and study, which embraces for the first class questions of the following nature:—"His farm of 600 acres, one eighth of which is always to be in beet-root, is to be divided into the most eligible rotation of crops; show the most profitable course, and describe the nature and chemical properties of the soil in each field, the proper manures to be applied to them, the quantity of seed required for the crop, its culture by previous ploughings, by after-hoeing or weeding, and the cost and labor, and the probable return!"

The plans of farming given by some of the youths, would have done credit to an experienced farmer, and demonstrated clearly that though theory alone in farming is an absurdity, the combination of the practice with scientific acquirements, will soon operate great melioration in the agricultural world. From three till seven they prosecute their labor in the fields, being eight hours work in the day. They then come in for dinner. At eight the director receives the report, from every decurion, of the day's work of his party of ten. He then orders the work for the ensuing day, giving a concise lecture on the subject when necessary to the culture of any unusal crop. A library of agricultural works is open to the students till bed time, quarter past nine. * * * The crop that appeared to me to be most carefully cultivated, was beet-root in drills, which produced per acre about 750 pounds of sugar, selling at ten pence per lb. as fast as it could be manufactured.

Science of Gardening.—*Continued.*

POTASS.

When wood or any garden plant is burned to ashes, these are found to consist of a considerable portion of the substance termed potash, which was discovered by Sir H. Davy to consist of a metal termed potassium combined with oxygen and water. Different sorts of plants, however, vary very much in the quantity of potass which they contain; aspen and box-wood, for instance, containing only sixty or eighty pounds in every thousand pounds weight, while sunflower, fumitory, and wormwood contain from three hundred and fifty to seven hundred and fifty pounds in every thousand. Sea weeds and plants growing close by the sea shore, instead of potass, yield soda, when they are burnt to ashes.

It may be taken as a general rule, that the herbs yield four or five times, and shrubs two or three times, as much impure potass as trees; while the leaves produce more than the branches, and the branches more than the trunk; and further, that plants, when green and fresh, yield more than when they have been previously dried.

The process by which this is ascertained is not difficult, and consists in weighing the plant before burning; in washing the ashes twice in their own volume of water; in passing the washings through blotting paper; and in evaporating them to dryness. The dry substance thus obtained will be probably pure potass.

The potass is introduced into the system of a plant in the same way as carbon, by being first combined with humic acid, forming humate potass, and then dissolved in water.

LIME.

Like potass, lime has been proved to be composed of a metallic substance termed calcium, united with oxygen. When thus composed, with the addition of other substances, it is usually called quicklime; when united with carbonic acid, it forms chalk, limestone, marl, and marble; and when united with sulphuric acid, it forms gypsum, or plaster of Paris.

In the proceess of burning vegetables, lime is found in their ashes, but never, I believe, in such quantities as potass, and consequently it is of less use to supply soils with it artificially on this account; but on account of its uniting with humic acid in form of a humate, and of the compound thus formed being readily dissolved in water, it becomes highly useful.

If quicklime, either fresh burnt or slaked, be mixed with moist vegetable substances, however hard and fibrous, it soon destroys their texture and forms a mixture, the greater part of which can be dissolved in water, thus rendering what was previously useless, fit for the food of plants.

On the other hand, it is injurious to mix quicklime with vegetable substances already soluble in water, or with any sort of dung, or other animal manure, lest it should take up too much humic acid.

Lime, however, is more seldom used in gardens than in farms, and this is so far judicious, that garden soil would often, as appears from what has just been said, be thereby injured rather than benefitted.

SUGAR AND GLUTEN.

There are few plants that do not contain sugar, which chemists have shown to be composed of about three parts carbon, four parts oxygen, and eight parts of hydrogen.

It should follow, therefore, that it is not necessary for it to be introduced into the soil in the state of sugar, the constituents being always more or less contained in the water, and most probably combined into sugar after entering the system of a plant. This applies also to starch, which is composed on the same principles, and may indeed be converted into sugar, as was lately discovered: and gluten differs only in containing nitrogen, in addition to the carbon, oxygen, and hydrogen.

In a word, all substances of this kind which can be discovered in the soil, or in the water diffused through it, may be resolved into water, carbon, and nitrogen; and hence it is of less consequence for our present purpose to notice separately every compound that might be enumerated.

RECAPITULATION, AND PROOF FROM THE SAP.

It hence appears, that the chief food of plants is carbonic acid gas, atmospheric air, and the humates of potass and lime mixed with water, and presented to the spongelets or suckers at the tips of the root fibres, to be thence carried into the interior of the plants. The examination of the sap, as it rises from the root into the inner bark of a tree, confirms the truth of these statements.

This sap is usually found to be a clear fluid, of a pleasant taste, readily fermenting, and, in that case, giving out, at first carbonic acid gas, and afterwards some azote. The chief portion of the sap is water, and it only differs from the moisture of the soil by acquiring in its passage upwards a portion of thicker fluid, which probably acts a part similar to the saliva of animals, mixed with the food in chewing, or to the digestive fluid in the animal stomach. By means of this, the sap becomes thicker the higher it rises. M. Biot, of the French Institute, is at present, 1833, engaged in experiments which bid fair to elucidate this important subject. His tests of the substances contained in the sap are made by the polarisation of light.

Young Men's Department.

Hints to Young Farmers—No. IX.

DO NOT GET ABOVE YOUR BUSINESS.

One of the most fatal errors which young men are apt to commit, is, when they have acquired the means of a comfortable independence, and are established in doing well enough, *to get above their business.* They are apt to relax in those labors, or in the supervision of them, which led to success—or to become dissatisfied with their moderate but certain gains, and seek to better their fortunes, and to elevate their standing, by embarking in some new business, to which they are yet strangers.

It should be your aim, first, to make yourselves practically acquainted with the best modes of performing every operation of the farm; and, secondly, constantly to superintend and direct those you employ in these operations. There is hardly any business in life, in which success does not materially depend upon the practical knowledge and rigid supervision of the master. If you would have your work done, *see* that it is done—if you would have it well done, *lead* in its performance. It will impair neither your physical nor intellectual powers, but invigorate and strengthen both. There are very few sufficiently trust-worthy and intelligent, to be charged with the entire management of a business in which they may be considered as mere hirelings. And unless the master is a proficient in the business he is carrying on, in all its minutiæ—unless he knows how every operation *should* be conducted—the *time* it will require to perform it, and see that it is *done well*—he is subject to constant impositions, disappointments and losses. Hence we see, that not only in farming, but in most other employments, unless a man has practical knowledge, as well as theoretical, in the business he carries on, he is far less likely to succeed, than others who possess this practical knowledge. A man may be made to comprehend, very well, the plan and construction of a house, or the principle of amputating a limb of the human frame; yet, until his hand is practised in carpentry, or in surgical operations, we should hardly venture to trust him to build our house or to cut off our leg. These remarks apply to the minute, as well as to the more enlarged operations of the farm. If your workmen have confidence in your knowledge and judgment, and are aware of your critical supervision of your affairs, they will labor cheerfully and diligently, respect your authority and carry out your views of improvement. Hence, we repeat, make yourselves practically acquainted with every operation in farming—though you do not practise it after you have acquired that knowledge—be the manager of your own affairs as far as possible—avoid the temptation to change, to indolence and to speculation, and be assured you will not fail to enjoy, in a large measure, the substantial comforts and pleasures of life. And having realized these blessings yourselves, take care to secure them to your children, by inculcating and establishing in them, the principles and habits which have led to your individual success.

Another common propensity to error, in the farmer, is to ape the follies, the fashions and the extravagance, in dress, equipage and supernumerary servants, of what are termed the higher classes in society—which seldom redound either to our comfort, to our rational gratification, or to our respectability in life. An old veteran of the revolution, who had acquired a fortune by prudent industry, once remarked to us, that to gratify the feelings of a young family, he set up a coach. He was obliged, he said, to have horses and harness, and household furniture to correspond. His coachman required an extra maid to wait upon him, and the maid required a scullion to wait upon her; and he found, that instead of being master, and enjoying his quiet, he became virtually the servant to the coachman, maid and boy. So that after spending a thousand dollars a year, barely upon his coach establishment, he sold out, dismissed his supernumeraries, and returned to his Dearborn wagon and horse, to the great relief of both his mind and his purse. It is commendable to endeavor to multiply around us the comforts, and even the innocent delicacies and elegancies of life; yet it is folly to adopt habits, either from ostentation, or a spirit of foolish rivalship, which are not adapted to our employments or our means, and are not calculated to make us either wiser or happier. Gentility, that is, politeness of manners, and easy, graceful behaviour, may be cultivated in the country as well as in the city—as well upon the farm as behind the counter. It is neither the coach, nor the gay dress, nor the ostentatious display, nor the title, that makes the gentleman, nor insures happiness. For, as Burns sings, though

> "The king can make a better knight,
> A marquis, duke and a' that,
>
> * * *
>
> The pith of sense, and pride of worth,
> Are grander far than a' that."

Chemical Catechism—Chapter III.

OF CALORIC.

What is heat?

Heat is the well known sensation which we perceive on touching any substance whose temperature is superior to that of the human body.

What name is given to the matter of heat?(*a*)

Chemists have agreed to call the matter of heat *caloric*, in order to distinguish it from the sensation which this matter produces.(*b*)

What are the principal uses of caloric?(*c*)

Caloric is every where indispensable to the existence of man. "It is with fire that, in every country, he prepares his food, that he dissolves metals, vitrifies rocks, hardens clay, softens iron, and gives to all the productions of the earth the forms and combinations which his necessities require."

What are the sources of caloric?

There are six sources from whence we procure caloric, viz. from the sun's rays, by combustion, by percussion, by friction, by the mixture of different substances, and by means of electricity and galvanism.

Which of these is the principal source of caloric?

The sun is the chief, and, probably, the original fountain which furnishes the earth with a regular supply, and renders it capable of supporting the animal and vegetable creations.(*d*)

How is caloric furnished by combustion?

The oxygen gas of the atmosphere is *decomposed* by combustion; and caloric, one of its component parts, is set at liberty.

How is caloric produced by percussion?

The heat produced by percussion is generally occasioned by the *compression* of the particles of the body, which compression forces out a portion of its latent caloric.(*e*)

How is caloric produced by friction?

It is not known how friction produces caloric,(*f*) unless we suppose it to be a succession of percussions.

In what way can heat be produced by means of electricity or galvanism?

By the discharge of an electrical battery, or by the galvanic apparatus, a more intense degree of caloric may be obtained than by any other means whatever.

How is caloric produced by mixture?

When heat is produced by the mixture of two or more substances, it is owing to the fluid part of the mixture taking a more solid form; for neither water nor any other fluid can acquire an increase of density without giving out a portion of its latent caloric. (*g*)

You speak of latent caloric; is there any difference in the nature of caloric?

No: we have reason to believe that caloric is uniform in its nature; but this term is necessary because there exist in all bodies two portions of caloric, very distinct from each other.(*h*)

How are these two portions of caloric distinguished?

The one is called *sensible* heat, or free caloric; the other *latent* heat, or combined caloric.

What do you mean by free or sensible caloric?

Sensible caloric is the matter of heat disengaged from other bodies, or, if united, not chemically united with them.

What is latent caloric?

Latent caloric is that portion of the matter of heat which makes no *sensible* addition to the temperature of the bodies in which it exists.

What substances contain latent caloric?

Caloric in a latent state exists in all substances that we are acquainted with.(*i*)

Do all substances contain the same quantity of latent caloric?

No: caloric combines with different substances (*j*) in very different proportions; and for this reason one body is said to have a greater *capacity* for caloric than another.

Is this capacity for caloric uniformly the same in the same bodies?

The same bodies have at all times the same capacity for caloric, unless some change takes place in the state of those bodies.

Can you adduce instances of a change of this kind?

When gaseous substances become liquid, or liquid substances become solid, they lose in a great measure their capacity for caloric: accordingly, when solid bodies become liquid or gaseous, their capacity for caloric is proportionately increased.(*k*)

How does this property of bodies operate?

Whenever a body has its capacity for caloric thus increased, it requires a larger portion of the matter of heat to raise it to a given temperature, than another body does which has a less capacity for caloric.

Can you exemplify this curious property of matter?

If equal quantities by weight, of water and mercury, cooled down to the same point, be afterwards separately heated to the heat of boiling water, the water will be found to have required more than three times the quantity of caloric that the mercury did to bring it to that temperuture.

What term is made use of to denote the quantity of caloric thus required?

The portion of caloric necessary to raise a body to any given temperature is called the *specific* caloric of that body?

Is there any method of ascertaining the specific caloric of different bodies, and comparing the relative capacity of each for caloric?

An instrument called a *calorimeter* is used for this purpose. The substances to be tried are heated to the same temperature, and then placed in this machine surrounded with ice.(*l*) By observing how much ice each of them melts in cooling down to a given point, the specific caloric which each of them contained is determined.

What do you call the instrument which is in common use to measure the temperature of bodies?

It is called a thermometer. (*m*) It consists of a glass tube containing a portion of mercury, with a graduated plate annexed to it. The tube is hermetically sealed, to preserve the metal from the pressure of the atmosphere.

Do you understand how a thermometer is affected by the temperature of bodies?

When a thermometer is brought in contact with any substance, the mercury expands or contracts till it acquires the same temperature,(*n*) and the height at which the mercury then stands in the tube, indicates the exact temperature of the substance to which it has been applied.

Will the thermometer show the exact quantity of caloric in all bodies?

No; it will not show that portion which is latent, or chemically combined with any body: for instance, fluids require a certain portion of caloric to keep them in a state of fluidity; which portion is not indicated by the thermometer.

Is the thermometer, then, of no use in ascertaining the temperature of fluids?

Yes: all fluids operate upon the thermometer in the same manner as solids; for, whatever sensible caloric be contained in any liquid, that portion is accurately shown by the thermometer.

What do you call that portion of caloric which is a necessary part of fluids?

It is called the caloric of fluidity; but different fluids require different portions of it to preserve them in the state of fluids.

What are the effects of caloric upon bodies?

The *general* effects of caloric are, to increase the bulk of the substances with which it unites, and to render them specifically lighter than they were before; but in whatever quantity it is accumulated in bodies, it never adds to their absolute weight.

What are the PARTICULAR *effects of caloric on bodies?*

It favors the solution of salts, and promotes the union of many substances. In other cases it serves to separate bodies already united,(*o*) so that in the hands of chemists it is the most useful and powerful agent we are acquainted with.

Can you recollect any other particular effect that caloric has upon bodies?

It is the cause of fluidity in all substances which are capable of becoming fluid, from the heaviest metal to the lightest gas.

How does caloric act upon hard bodies to convert them into fluids?

It insinuates itself among their particles, and invariably separates them in some measure from each other. Thus, ice is converted into water, and by a further portion of caloric into steam.(*p*)

How are these substances distinguished which are capable of being thus rendered fluid by caloric?

We have reason to believe that every solid substance on the face of the earth might be converted to a fluid, or even a gas, were it submitted to the action of a very high temperature, in peculiar circumstances.

You say the sun is the great source of caloric; how is caloric transmitted from the sun to us?

Caloric is transmitted to us accompanied by light: both are perpetually thrown off from that immense body with astonishing velocity in every direction.

If caloric passes with such velocity, how is it retained by those substances which receive it?

It is retained by its affinity for those bodies, or rather, their mutual affinity for each other.

Do bodies in general possess a very strong chemical affinity(q) for caloric?

No: it is one of the weakest of all known affinities, which is evident from the facility with which heated bodies part with their caloric to all surrounding bodies.

Is this universally the case?

Yes; it seems to be one of the laws of nature, that heated bodies should give out *part* of their free caloric to the neighboring bodies at a lower temperature, till the whole become of an equal degree of temperature.

Give me an instance of the operation of this law of nature.

When the temperature of the atmosphere is reduced below 32°, water gives out its superabundant caloric by degrees, till at length the cold atmosphere robs it of its caloric of fluidity also, and it becomes ice.

If water be changed into ice by parting with its caloric, how comes it to pass that ice swims upon the surface of water?

Because, by the change which it undergoes, it becomes specifically lighter than the subjacent water.

Did you not say that all substances become more dense by the loss of caloric?

They usually do; but the freezing of water is a striking *exception* to this general law of nature, and is a memorable instance of the wisdom and provident care of the Almighty, when he established the laws of the universe.

NOTES.

(*a*) The sensation of heat and cold arises from the tendency which caloric has to diffuse itself equally amongst all substances that come in contact with it. If the hand be put upon a hot body, part of the caloric leaves the hot body, and enters the hand; this produces the sensation of *heat*. On the contrary, if the hand be put upon a cold body, part of the caloric contained in the hand leaves the hand to unite with the cold body: this produces the sensation of *cold*.

(*b*) In order to give precision to chemical language, it was necessary to find a term to distinguish the matter of heat from its effect; for whenever caloric becomes fixed in a body, it loses its property of affording heat. Nothing can be more evident than that caloric may exist in many substances, without producing any of the effects which arise from the agency of fire.

(*c*) Many of the uses of fire will immediately occur to every individual, whenever the importance of this subtle fluid is alluded to; though perhaps the wisdom of the Deity, in giving the use of it to man only, has not been often noticed. Why has this powerful agent been solely entrusted to man? Why was every fowl of heaven, and every beast of the field, impressed with an unconquerable dread of approaching it? If it were at the disposal of animals, which of our possessions, or even of our lives, would be safe for a single moment?

(*d*) According to the laws of nature, animal and vegetable life are both very much influenced by the temperature in which they exist; we therefore find different kinds of vegetables, and a different race of animals, appropriated to the different climates of the earth.

That caloric is as necessary for the support of vegetable as for that of animal life, may be proved by direct experiment. If, in the midst of winter, a hole be bored in a tree, and a thermometer be put into it, it will be seen that the tree is many degrees warmer than the atmosphere.

(*e*) As evaporation produces cold, condensation always occasions heat; that is, caloric is always evolved from those bodies which have undergone any degree of condensation. In one case caloric is absorbed; in the other it is set at liberty.

By the collision of flint and steel, so much caloric is disengaged, that the metallic particles which are struck off are actually melted thereby. This is evident from their being always found in a spherical form.

(*f*) Instances have occurred where whole forests have been burnt down, by fires kindled from the violent friction of the branches against each other by the wind.

(*g*) Sulphuric acid and water experience this condensation by mixture, which is proved by the measure of the fluids, before and afterwards, and by the heat that is evolved. If four parts of the former be mixed with one of the latter, the mixed fluids will quickly acquire a temperature higher than that of boiling water. It is necessary to be cautious in making this experiment.

If iron filings and sulphur be mixed into a paste with water, a sulphuret of iron will be formed, which decomposes the water and absorbs oxygen so rapidly that the mixture takes fire, even though it be buried under ground.

Mixture does not uniformly produce heat. The mixture of some substances produces an intense cold. But the cause of both effects is easily explained. Whenever substances become more condensed by mixture, heat is evolved; when they expand, cold is produced; or, in other words, the compound has a greater or less capacity for caloric than the separate ingredients. The mixture of crystalized muriate of lime and snow produces the greatest degree of cold yet known.

(*h*) How the same substance may exist in a body in two distinct states, may easily be explained by the familiar example of a piece of common bread which has been dipped in water. This bread will contain two portions of water very distinct; one of them is in a state of combination, and forms a constituent part of the bread; the other is only interposed between the particles of the bread, and may again be forced out by pressure.

(*i*) Caloric pervades all bodies; this is not the case with any other substance we know of—not even light. It lies hid in every thing around us. It is a substance which we are ever in want of; it is therefore deposited on every side, and is ready for every exigency.

(*j*) Caloric, as it penetrates bodies, frequently forms a chemical combination with them, and becomes essential to their composition. This is always the case when a solid is converted to a liquid, or when a liquid passes to a gaseous state. But if caloric be superadded to a body when it is in a state of saturation, it merely traverses its surface, and passes from it, in the form of sensible heat, to some of the adjacent bodies.

(*k*) The freezing of water and the cooling of melted lead, may be adduced as familiar examples of the former; and the absorption of caloric in the melting of salts will sufficiently exemplify the latter. By the solution of some salts, water may be deprived of so large a portion of its caloric as to be frozen in the midst of summer.

When water is poured upon dry pulverized plaster of Paris, in order to form cornices for rooms, great heat is produced by the mixture. This is owing to the water giving out its caloric of fluidity as it becomes solidified in the plaster.

Whenever caloric becomes active, it produces heat; when it passes into a latent state, it produces cold.

(*l*) Ice has the property of absorbing all the caloric with which it comes in contact, and communicates no part of it to the surrounding bodies till the whole of the ice is melted: therefore the specific caloric of bodies may be easily be calculated by its means.

(*m*) Thermometers are made by putting mercury into small glass tubes with bulbs, and heating these bulbs till the mercury boils. This ebullition forces out the air, and the tubes are hermetically sealed while the mercury is boiling; which preserves the vacuum. They are afterwards graduated by a correct scale.

(*n*) The absolute necessity there was for an instrument of this kind may be shown by the following simple experiment: If the bulb of a thermometer be immersed in a mixture of snow and common salt, the mercury will fall to at least 32° below the freezing point of water; and if the instrument be then removed from that mixture and put simply into a mass of snow, the mercury will be so much heated by the change, as to rise 32°; so that snow which appears to the hand to be totally devoid of all heat, contains sufficient to raise the thermometer many degrees.

(*o*) Caloric also promotes the decomposition of bodies, by reason of its counteracting the attraction of cohesion which exists in all bodies.

(*p*) In India and China the wealthy have their rooms open on all sides, the roof being supported on pillars, and the intervals hung with curtains. Servants without doors scatter water on these curtains continually: its evaporation absorbs a vast deal of heat, and makes the apartments cool and refreshing.

(*q*) Before a youth can have an accurate idea of chemical attraction, the nature of philosophical attraction should be explained to him, by means of a magnet and iron filings; by globules of water, of mercury, &c.

"What do you teach the girl?" asked Maltravers of the school-master. "That God made her, and that he loves good girls, and will watch over them." "What else?" "That the Devil runs away with bad girls, and"——"Stop there: never mind the devil yet awhile. Let her first learn to do good, that God may love her; the rest will follow. I would rather make people religious through their better feelings, than through their worst. We can do without the devil at present."—*Bulwer.*

There is nearly always something of nature's own gentility in every young woman, (except, indeed, when they get together and fall a giggling.) A vulgar boy requires, heaven knows what assiduity, to move three steps, I do not say like a gentleman, but like a body that has a soul in it; but give the least advantage of society or tuition to a peasant girl, and a hundred to one, but she will glide into refinement, before the boy can make a bow without upsetting the table.—*Ib.*

*Moneys received during the last month, in sums of five dollars and over. The total receipts are included from post-offices marked with an asterisk.**

THE CULTIVATOR:

A MONTHLY PUBLICATION, DEVOTED TO AGRICULTURE.

I KNOW OF NO PURSUIT IN WHICH MORE REAL AND IMPORTANT SERVICES CAN BE RENDERED TO ANY COUNTRY, THAN BY IMPROVING ITS AGRICULTURE.—*Wash.*

VOL. V. NO. 3, WASHINGTON-ST. ALBANY, N. Y. AUGUST, 1838. NO. 6.

Conducted by J. BUEL, of Albany.

TERMS.—One Dollar per annum, to be paid in advance. Subscriptions to commence with a volume.

Special Agents.—L. & R. Hill, Richmond, Va.; Bell & Entwisle, Alexandria, D. C.; Gideon B. Smith, Baltimore, Md.; Judah Dobson, bookseller, and D. Landreith, seedsman, Philadelphia; Israel Post, booksellers, 88 Bowery, Alex. Smith, seedsman, P. Wakeman, office of the American Institute, Broadway, N. York; E. M. Hovey, Merchants's Row, Boston; Alex. Walsh, Lansingburgh, and Wm. Thorburn, Albany, gratuitous agents. For general list of agents see No. 12, vol. iv.

The Cultivator is subject to common newspaper postage.

☞ Price of the published volumes, 50 cents per vol. stitched—the four volumes bound together, $2.75—bounded in two volumes, $3—the four vols bound each separate, $3.25.

THE CULTIVATOR.

TO IMPROVE THE SOIL AND THE MIND.

The Crops.

We do not remember any season in which the crops are so generally promising as in the present.—At the time of writing, July 2, the remark applies to every description of crop, and to every section of the union, so far as we have observed, and have been able to learn. The wheat crop has, however, two formidable enemies to encounter this month—the grain worm and the rust. The former was seen in our fields for the first on the 24th of June. It might probably have appeared as early as the 20th June; and the last time we were able to discover it was on the 20th of July—when spring wheat, sown on the 16th May, had been a few days in head. ☞ We shall be obliged to any gentleman who has watched this insect, to apprise us of the times at which it appeared and disappeared.

During a jaunt of 200 miles into Vermont, in the last of June, we were gratified at the highly auspicious promise of the crops; and not a little surprised to find the corn, from Bennington to Rutland, in a better and rather more forward state than it was in the upper valley of the Hudson. This we ascribe to early planting, early variety, and the use of long manure. On the 19th of June we saw part of a field in tassel, at Wallingford. We planted some of the same kind on the 24th, and expect to see it come to maturity this season.

Common School Libraries.

We were unadvised of the fact, until we saw it announced in a late *Jeffersonian*, that the legislature made an appropriation at its last session, of $45,000 per annum, for three years, for the establishment of common school libraries. We fully concur in the sentiments expressed in the following extract which we make from the Jeffersonian, as to the salutary influence which this judicious appropriation is likely to have in enlarging the sphere of useful knowledge, and in improving the condition of the producing classes of the community.

"We trust no friend of the great cause of universal education, no parent, no youth, no lover of his country, has forgotten or will forget the provision so wisely made by our last legislature for the establishment and support of COMMON SCHOOL LIBRARIES. We feel a proud satisfaction in contemplating the fact that New-York stands forth in this matter a pioneer and a glorious example to her sister states. The law making provision for the distribution of the annual revenue of the new common school fund, (arising from the deposite of the late surplus revenue with the states,) appropriates forty-five thousand dollars a year exclusively to this benificent purpose. Each district in the state is entitled to draw its share of this fund, proportioned to the number of its scholars; and, estimating the whole number of districts at forty-five hundred, this sum would allow an average of ten dollars to each district, or thirty dollars in the course of the three years' duration of the law. We believe this estimate is rather under than above the truth; and that, with a very moderate display of public spirit on the part of the people, a very comprehensive and most useful library may be immediately secured to every school district in the state.

"The great advantages of this noble enterprise to that very large proportion of our citizens who are unable to buy large collections of books cannot be over-estimated. Not alone to children and youth will its benefits be dispensed. Parents and others of mature years can readily avail themselves of the fund of useful and instructive reading which is thus brought to their doors. Even should the library consist of but fifty volumes at first, each family in the district may draw one volume from it per week for the whole year, returning it at the week's end for another; and thus enjoying a supply of information and entertainment for the whole period without the cost of a cent. At the end of the year, a new instalment of the appropriation will be doubled, and another year's reading commenced. We firmly believe that in this way the library will be found a great auxiliary to the school, by creating a new interest in its management and its welfare. Should the district conclude to have a little gathering every Saturday evening, or some other evening, to exchange books, or return and draw again, a lyceum, or association for mutual improvement, would soon grow out of it, and still greater benefits be realized. Each parent and scholar would feel that he had a personal interest in the library as well as the school; and thousands would spend their leisure hours in reading, which would otherwise be given, almost of necessity, to frivolous if not corrupting amusements."

Thus far our quotation. But we are not prepared to go farther with the Jeffersonian—in its approbation of the selection of books designated and recommended as the *basis* of common school libraries. The Messrs. Harpers, to whom we accord great credit for their enterprize and industry, have printed, we are told, under the direction of the American Society for the diffusion of useful knowledge, a series of 50 handsome volumes, of uniform size and appearance, to be comprised in a neat case, and furnished at twenty dollars. These books, of which a list is given in the Jeffersonian, treat mostly of foreigners, foreign lands, and of matters foreign to the great pursuits of our country. They are the lives of Bonaparte, Alexander the great. Peter the great, Oliver Cromwell, of celebrated travellers and female sovereigns; ancient and modern Europe, the Holy Land, the Crusades, Arabia, the Chinese, voyages, travels, &c. We see but eight volumes that seem from their title to relate particularly to our continent, and but about the same number that are written by Americans. But we do not recognize one, among these books—which are designed almost exclusively for an agricultural community—we do not recognize a single volume on agricultural chemistry, or on agricultural botany, or on agricultural geology—or on the mechanics of agriculture, the great modern lever which simplifies, abridges, and at the same time augments the products and profits of human labor; we see nothing on the veterinary art, or the management of cattle—nothing upon practical agriculture or horticulture—and little, if any thing, upon the moral, relative and political duties of life. The studies to which we have last alluded, ought to form the foundation, the basis, of a rural education; those selected might become auxiliary, or supplemental; or, the two classes might be blended like brick and mortar in the walls of a building, to give beauty, as well as solidity, to the structure.

It needs no argument of ours to convince any reasonable man, that the proper study of youth, is the business which is to employ them in manhood. Thus we give to the law student elementary books in the business which is to constitute his living; and to students in divinity and physic, the elementary books suited to their several professions; and we require a four years' study in these elementary works, in order that the student may fully understand the principles upon which he is to preach or practice, before we permit him to put on the toga of manhood, and to take rank with his profession. And shall not the student of agriculture, whose business embraces a wider range of useful science than either of the before mentioned classes, be permitted, during his minority, to study the elementary principles of *his* profession?—to store his mind with the precepts and practices of eminent men in that profession? We say, lay the *foundation* in usefulness—in that knowledge which will tend to make intelligent, useful and contented farmers, and good citizens, of the boys of our common schools. You may then build whatever superstructure you please upon this solid foundation, and embellish it to your taste.

But we are reminded, that we are treading on hallowed ground; that the society for the promotion of useful knowledge, with Gov. Marcy at its head, have sanctioned the selection that has been made, and, as if to silence every doubt, that Gen. Dix, superintendent of common schools, has also given it his approbation. Without wishing to derogate in the least, from the high character of the gentlemen who constitute the society, or to depreciate their efforts to do good, we must be permitted to doubt their pre-eminent qualifications for selecting a suitable library for an agricultural community. Most of the gentlemen, we believe, belong to the learned professions, or to the mercantile class; and we are willing to award to them a high standing in literature and general science; yet few of them, we apprehend, know much of the practice or theory of farming, a business which stands first on the roll of usefulness, and which it is the interest of every class of the community to enlighten and improve; and they are therefore not exactly best qualified to promote this great object of national prosperity, be their intentions ever so patriotic. Or at least so we are obliged to infer, from the catalogue of books which have been published. And as for our highly respected secretary of state, he is no doubt well qualified to select a law or literary library, or to thread the mazes of politics—yet we should not venture to trust him, with all his qualifications, to select *our* library, or manage *our* farm. Would these gentlemen trust an association of farmers, however intelligent, to select their *professional* libraries? We think not.

But perhaps we are going too far: something on agriculture is promised in the next series, and we ardently hope it will be furnished.

After all, it may be said, and will be said, and by thousands of farmers too, that agriculture wants no auxiliary aids; that it has done well enough, heretofore, without the aid of books or of science—and that it can continue to do so. How would such a remark apply to the other arts of labor? Look at the cotton factory for instance—a yard of cotton goods may now be purchased for half the price which was paid for barely *weaving* a yard thirty years ago. The manipulations in most of the other arts have been so abridged by machinery, and the processes so simplified by science, that the fabrics produced by these labors are greatly lessened in price. In these arts, the improvements of the age are speedily registered and promulgated in books and periodicals. Mechanics and manufacturers know how to appreciate this sort of book knowledge; and it enables them to keep pace with the improvements of the age. Not so our farmers generally. They have little intercourse with each other; they have no access to agricultural books, and many are too old or too prejudiced to seek for or receive information. The consequence is, that we are making slow progress in agricultural improvement, while agriculture is being made to double, treble and quadruple its products upon the old continent. Youth is the appointed time, and the only time that can be relied on, for implanting the knowledge and the principles which should guide and govern in the business of manhood—and of laying the foundation for good citizens and intelligent prosperous farmers.

The Strawberry.

As the present month and the beginning of September, is the best season for making strawberry beds, some remarks as to varieties and the mode of culture may not be unacceptable.

The fruit of the strawberry is almost universally esteemed; and is prized as well for its delicious flavor, as for its tendency to promote health, and for its efficacy in mitigating or curing certain diseases.—The berries are almost wholly soluble in the stomach, and neither there or elsewhere do they undergo the acetous fermentation. They dissolve the tartareous incrustations of the teeth. They promote perspiration. When used largely, they have given relief to those afflicted with the gout; and Hoffman states, that he has known consumptive people cured by them. The principal species and varieties are—

1. *Wood*, with oval serrated leaves; the fruit round and small, and white and green. Native of Britain.
2. *Scarlet*, with leaves like the preceding, roundish and scarlet coloured. Native of North America. Varieties: early scarlet, Wilmot's late, common late, Wilmot's scarlet.
3. *Roseberry*. A Scotch seedling. The plants have few roundish leaves, larger fruit than the scarlet, and are very prolific. Continues bearing till August.
4. *Downton*. Fruit large, irregular and coxcomb-like; leaves large; plants hardy; and although prolific in England, has not proved so with us. We have grown a berry that measured 5 3-4 inches.
5. *Carolina*, or *Bostock*.
6. *Musky*, or *Hautboy;* with oval, rough, javellin edged leaves, the fruit large, of a pale red.
7. *Chili;* with large oval, thick hairy leaves and large flowers; the fruit large and very firm. A native of Chili.

8. *Keen's Imperial*, or *New Chili;* a large showy fruit, of great repute in England, but not so much esteemed here.

9. *Pine;* the leaves small and delicate. There are two sorts, the red and the white, or greenish-tinted, of the most rich flavored fruit. The Methven Castle belongs to this class. South America.

10. *Alpine*, or *prolific*, or *monthly;* commonly lasts from June to October; two sorts, white and red.—The Alps.

11. *One leaved;* the pulp of the fruit pink colored. South America.

We received twelve kinds of select fruit from the London Horticultural Society, in 1825; but continue to cultivate in our garden only the Methven and scarlet,—the latter coming in use ten or fourteen days before the former,—both abundantly prolific. Some of our beds are six years old, and they have produced as abundantly this as in any former year. We ascribe this continued productiveness to our pointing in horn shavings annually between the beds, and strewing upon the latter in autumn tan from the morocco leather factory. The Methven is in bearing about two weeks; we have had 47 berries that weighed a pound, many that measured over four, and one that measured five and one-quarter inches in diameter. Our practice is to clean the alleys and beds before the blossoms show, to leave the runners till the fruiting season is over, and after that to take off those that intrude upon the alleys, and to dung and dig these.

The strawberry multiplies rapidly by suckers or stolens, and may be transplanted as soon as the leaves have grown at the joints, although the roots are but imperfectly formed. If planted out in this month, they will give a partial crop the next season, and will be in high perfection the second year.

Mr. Keen, near London, who appropriates acres to the growth of this fruit, recommends that the pine be grown in a light loam, though no kind will grow better in a stiff one. The imperial and scarlets like a similar soil. The hautboys like a light soil. The wood strawberry is generally raised from seed, and the alpine always. The seed is best sown as soon as the fruit ripens; the plants to be set in fruit beds the spring following. Our own experience leads us to recommend, that the pines and scarlets be planted in a loose, rich, and pretty moist soil, our climate being dryer than that of Britain, and the strawberry demanding a great supply of moisture when fruiting.

The mode of planting is generally in beds containing two, three or four rows, with alleys of two feet between them. The soil should be well dug and pulverized, and the situation open and exposed to the sun. The larger growing kinds may have intervals of two feet between the rows, and of 18 inches between the plants in the rows; the smaller growing kinds may be planted closer. Keen cuts the runners three times in a season—we cut them but once, and leave then the new plants that take root in the beds, mostly to grow. His culture may be the most perfect, but ours is attended with the least labor, the cost of which is there trivial to what it is here. Keen plants the pines and hautboys 2 feet by 18 inches apart, and the scarlets 20 by 18 inches. He found among the many different kinds of hautboys, one which had the male blossom on one plant and the female on another; and experience soon taught him, that to render them fruitful, it was necessary to mix the two kinds in his beds, in the proportion of one male to eight females. Mr. Langworthy, of Cincinnati, and Mr. Downing, of Newburgh, think that the male and female blossoms grow on different plants, in other kinds of strawberry; but our limited experience has not enabled us yet to confirm their opinions. The duration of most kinds with Mr. Keen, is three years,—the wood strawberry and alpine, two years. The latter bears fruit the first year after sowing.

The general dependence, in the country, for the strawberry, has been upon those growing wild in the fields; but independent of the fact, that this fruit cannot grow where the farm is well managed, the extra trouble of gathering them in meadows, is more than equivalent to the labor of taking care of them in the garden.

With regard to manures for strawberry beds, such are to be preferred as are cool, and free from the seeds of weeds. Cow manure is preferable to that of horses. Bone dust and horn shavings are excellent, if not applied in too large quantity. A bushel and a half of either should go as far as a load of long dung. For top-dressing the beds in autumn, there is nothing better than tan, that from the morocco leather factory being preferable. The tan smothers weeds, keeps the soil moist, the berries clean, and seems, withal, to afford the specific food of the plant. It is recommended to cover strawberry beds *lightly* with straw, in the spring, and burn it off, which destroys the seeds of weeds, &c. We have been cruelly censured for this recommendation, by one who unwittingly burnt *piles* of straw upon his beds, and consequently destroyed his plants.

On the proper time for cutting Grain.

"When the base of the stem of grain," says M. Biot, "begins to become yellow and dry, if the corn [grain] be then cut down, though the grain is not ripe, it will continue to be nourished at the expense of the green matter [elaborated sap] of the stem, almost, if not quite as well, as if it had remained uncut, and will thus ripen well; while, having been thus cut down early, much loss from shaking is prevented, beside the chance from *lodging* from heavy rain and wind." The editor of the Quarterly adds, "In a *fine season*, farmers cut down when they find the neck of the straw immediately under the ear, free of juice, when twisted round between the finger and thumb; and do not wait until 'the lower part of the stems are yellow and dry,' because they find in such a season the straw *to die from the ear downward.* This fact, we conceive, does not militate against Mr. Biot's *theory*, for as the absorbing power of the ear at the top of the stem is always powerful, it must be the more powerful the nearer the ear approaches maturity, and, of course, the part of the stem nearest the ear should first become dry. In a bad season, on the other hand, the lower part of the stem first becomes yellow and dry, after which, of course, the crop is not allowed to stand; for, in such a season, the ear never becomes mature, having, of course, less absorbtive power, whilst the vitality of the root is early destroyed by the combined effects of bad weather, and ungenial state of the soil."

On Smut in Wheat.

The Quarterly Journal of Agriculture contains some lengthy and well written numbers on the diseases of grain, by Mr. John Donaldson—in which he notices the different theories which have had their day, and the different preventives which have been recommended; and finally gives us his own opinion as to the cause and means of preventing these evils. We design hereafter to take a more extended view of these interesting communications; but our present object is merely to state the result of some experiments made by the writer, and to notice some of the means of preventing smut in grain, which he considers the most approved.

It is well to premise, that Mr. D. considers smut a parasitic plant, and that it is contagious, or in other words, that smut-powder abounds in minute seeds, capable of germinating and producing its like, when sown with wheat. To destroy the vitality of this smut seed, salt, lime, chamber ley, copperas, arsenic, &c. &c. used in steeps, have been employed, and proved more or less effectual. We select from the different receipts, two, on account of the facility with which they may be employed by farmers generally. One is, "a solution of common salt in water, strong enough to carry an egg, sometimes mixed with nitre and copperas, in which the wheat is steeped, the light grain being carefully skimmed off, and dried with quick-lime and then sown. In Norfolk, the salt is dissolved in a small quantity of water, barely sufficient for the purpose; the lime is slaked with this solution, and the wheat is dried with it in its hottest state, having been previously moistened with pure water." The second, practised in the south of Scotland and north of England, is, to steep the seed in stale urine, free of any mixture. In a practice of this mode of prevention, for forty years, Messrs. Culleys never had any smut. A tub holding a bushel of wheat, with a tin bottom pierced with holes, is immersed in the tub containing the urine, and after the wheat is repeatedly stirred, and the light grains skimmed off, it is thrown on a clean floor, encrusted with lime, and immediately sown. A short time only must elapse between this preparation and the sowing, as the corrosive quality of the volatile alkali with which the stale urine abounds, will destroy the vegetative power of the seed, especially if quick-lime be added."

Mr. D. gives the results of 16 experiments, made with wheat, variously prepared, and without preparation. Seed sown without any preparation, produced but one smutted ear in 434; but impregnated with smut-powder, two-thirds of the ears were smutted. Impregnated with smut-powder, and then washed in urine, the product was one smutted ear in five; and when lime was added to the washed grain, the proportion of smutted was only one to 11½. The four next experiments were made with grain impregnated with smut-powder, and arsenic, vitriol and copperas employed to purify it; and the results were, in the order named above, 1 to 14, 1 to 4, 1 to 16, and 2 to 1. Impregnated with chamber-ley and limed, the smutted ears were only in proportion of 1 to 47. This was far the most favorable result, though salt was not used in any of the experiments.

Arthur Young made several series of experiments with steeps, which are detailed in his Farmers' Calendar. Fourteen parcels were sown on adjoining beds. We give below the preparation and results.

No.	*Preparation.*	*No. of smutty ears.*
1,	Sown dry; nothing done to it,............	377
2,	Washed well in clean water,............	325
3,	Washed in lime water,..................	43
4,	Washed in a ley of wood ashes, ...	31
5,	Washed in an arsenic and salt mixture,....	28
6,	Steeped in lime water 4 hours, ...	12
7,	do in the ley 4 hours, ...	3
8,	do in the arsenic steep 4 hours, ...	1
9,	do in lime water 12 hours,..........	6
10,	do in the ley 12 hours, ...	0
11,	do in the arsenic steep 12 hours,......	4
12,	do in the lime water 24 hours,........	0
13,	do in the lye 24 hours, ...	0
14,	do in the arsenic 24 hours,..........	5

It would seem from the preceding results, 1, that steeping in lime water, or the ley of wood ashes, are either of them a pretty sure preventive of smut—if, in the second place, the grain is continued in the steep 12, or rather 24 hours. Every farmer has access to one or the other, or both of these, without much expense; and if, as we believe, they are, as well as salt and lime, destructive to the seeds of the smut, there is no excuse for omitting to employ them, or for marketing smutty wheat. It is, however, to be borne in mind, that when smutty wheat has been brought to the barn, unless great care is taken, it is likely to effect somewhat the coming crop, notwithstanding the seed may have been steeped; the seed of the smut being so minute and subtle as to adhere to bags, shovels, the floor, &c. and often to come in contact with the seed after it has been prepared. If wheat is made to follow after a crop of smutty wheat, a practice which should not be tolerated under any circumstance, the new crop will inevitably be smutty, as much of the smut seed will be scattered upon the soil, and will, of course, come in contact with the mouths of the young grain. But it is believed that the smut seeds lose their vitality, and will not grow after the first year; and that hence, if the seed is two years old when sown, the product will not be smutty.

Available Means of Agricultural Improvement.

Societies and premiums were tried in vain in Germany, to renovate agriculture, says Mr. Fleischman, and so was theoretical farming. "The practical farmer, uneducated and full of prejudice," he says, "was not able to understand the principles of the new system; the man of scientific education had no experience and knowledge of applying science to practice properly;" and so both failed, or improved slowly. At last, agricultural schools were established, and the science and practice were taught simultaneously. "In six years," he continues, "the influence of these schools was felt throughout the whole country." Rotation of crops was introduced; the stock was increased and improved; the fertility of the land was renovated; prejudiced neighbors became convinced; they began to imitate, to read, and to think, and in a short space of time, the old system was abandoned, and the farmer soon saw and realized the advantages of the *science* of agriculture."

"I look to the establishment of agricultural schools," says our highly intelligent Otsego correspondent, "as belonging to an earlier state of things than agricultural exhibitions. To him who has made no advance," he adds with great truth, "an agricultural exhibition is a source of mortification and a wounding of self-love—[because it throws his own labors and skill into the back ground]—but a school will awaken the spirit of improvement; and a few young men going forth from such an establishment, will be like a little leaven in the inert mass."

It requires but little reflection and foresight to predict, with great certainty, that unless something is speedily done, by the people and the people's representatives, to improve the state of our agriculture, the farmers of Europe will soon supplant—will undersell us—in our own markets, in the products of our soil. We already find the bread-stuffs of Europe, and even of Asia, put in requisition to feed our population. From the low price of labor in Europe, and particularly from the recent improvements in agriculture, which are doubling and trebling the products of agricultural labor there, the disparity in the actual cost, to the cultivator of these products, is constantly increasing against us. The venerable Fellenburgh—and may he yet enjoy a long and happy life—was the first to demonstrate the utility of combining the science with the practice of agriculture—of making farmers gentlemen, and gentlemen farmers—of combining intellectual with physical power, and literature with labor—in a school for the education of young men. The sagacious Frederick, king of Prussia, soon saw the advantages to the state, which were likely to result from schools like that at Hoffwyl, and soon established the great school at Moegelin, under the distinguished Thaer, and has since incorporated its principles into the common schools of his kingdom. Bavaria, Austria, and other of the German states, and France, have since established like schools; Russia has agricultural schools near St. Petersburgh and Moscow, liberally endowed and supported by the government; and even Ireland, it will be seen by the extracts in our last, has started in this noble career of usefulness. The United States, which should be foremost in efforts to enlighten, improve and elevate the agricultural population, will, we fear, be last to establish agricultural schools, and the last to profit by their usefulness.

The only present available means of accelerating the introduction of these schools among us—for established they ultimately must and will be—is the agricultural press—the enlarged circulation of agricultural periodicals among the people. We have now about twenty of these in our country. They are every day increasing the sphere of their usefulness, and the extent of their circulation. They are bringing into notice the best practices in husbandry, and promulgating the principles of agricultural science. They are producing a salutary change in the public mind, in regard to the importance of improving our husbandry; and this change will ere long, we trust, be felt and manifested in our halls of legislation. The sooner the better, for all classes of our citizens.

Utility of Agricultural Societies.

A national society, for promoting agricultural improvement, was about being organized at our last dates, in Great Britain, through the active influence of Earl Spencer, the Duke of Richmond, and other distinguished landholders. There already exists a Central Society of Agriculture, which may in some measure be termed a national institution. The rapid improvement of Scotch husbandry, under the invigorating influence of the Highland Agricultural Society, is operating as a powerful stimulus to the formation of a similar society in England. The Editor of the (London) Farmers' Magazine, speaks thus of the matter:—

"Attention is at length aroused," says the editor, "to the remarkable progress which agriculture has made in Scotland, and to the high rents cheerfully paid by the tenants there, although laboring under the disadvantage of a more inhospitable climate. That the Scotch are better farmers than the English generally, that they pay higher rents, and that their system of farming is improving daily, are facts at last unequivocally, though reluctantly admitted; and the question is very naturally asked, how has this been effected? How is it that our northern brethren, laboring under acknowledged disadvantages, have beaten us in the race? The answer is, by reducing the practice of, and improvements effected by, the most talented and skilful agriculturists, to writing, thereby establishing agriculture as a *science*, and again diffusing such information speedily and widely amongst the farmers. The effective attainment of both objects may be mainly, if not altogether, ascribed to the exertions of the Highland Agricultural Society. We have been always so deeply impressed with the high value of this society, that we have never failed to hold it up as a model to all other agricultural societies. A like opinion of its utility is rapidly spreading, as well as a desire to become better acquainted with the system of management adopted by the Scotch agriculturists."

The editor continues—"An agricultural society has been formed in Paris, which communicates with more than 200 local societies in different parts of France, and has correspondents in every part of the kingdom, besides more than fifty correspondents in almost every part of the world. New local societies are in course of formation daily, ploughing matches are introduced, a steam plough has been invented; and agricultural schools are established in different parts of France. The French possess several experimental farms, and the propriety of establishing agricultural colleges, for the instruction of youth, is strongly urged by the best practical writers of the day. At Petersburgh and Moscow, agricultural colleges are established. In Prussia, the king especially patronizes agriculture, and the academy at Frankfort, upon the estate called Moegelin, under the superintendence of M. Thaer, the most scientific agriculturist in the world, is well known. If we plume ourselves upon our superior knowledge, and regard with indifference the exertions made by our neighbors, we shall by and by discover to our disgrace and shame, and loss, that as in the case of the Scotch agriculturists, we shall have to go abroad for information,"—and, *we* may add, for BREAD!

Sir John Sinclair.

If substantial usefulness to the human family constitutes the criterion of merit—as it should do—few men are entitled to greater praise than this distinguished Scotsman. Many men have the talent to be useful, who lack the disposition. There are others, who have the disposition to be useful, but lack the talent, the means, or the resolution, of carrying out their benevolent wishes. In Sir John Sinclair, the talent, the disposition, the means, and the perseverance, necessary to accomplish great usefulness, were most happily combined, and by him they were most successfully employed. Such a man is a blessing to his country and to mankind. He saw the agriculture of his country, the great source of human subsistence and human comfort, in a wretched condition. He saw, that from the little intercourse the farmers had with other countries and other districts, from which they could draw instruction, that little improvement was to be expected, except through the united exertions of influential individuals, aided by the liberal patronage of the government.

Impressed with these convictions, he printed and circulated, in 1793, his plan for establishing a Board of Agriculture; and in a few days afterwards, he moved, in his place in parliament, an address to the crown, in favor of the proposed establishment, which was carried, 101 to 26, the board organized, and he made president. In a speech which he made while the subject was under discussion in parliament, he pointed out the obvious advantages which would result from the establishment. In the first place, according to his biographer, he regarded it as a general magazine of agricultural knowledge, and a society of reference, to which any question might be sent, connected with the improvement of the country. In the second place he shewed, that by agricultural surveys, carried on under the auspices of such a board, every fact or observation known in that country, connected with the improvement of the soil, or the stock it maintained, would be collected. In the third place, that by establishing an extensive foreign correspondence, the discoveries and improvements appertaining to other lands, would be much sooner and more widely rendered available, than if dependant wholly on private exertion. In the fourth place, that it was only through the means of such a board that any general improvement of stock could be looked for; and that, in the last place, it might be the instrument of obtaining a statistical account of England. Five thousand pounds—$22,000—was the annual grant, and the privilege of franking was given to the board.

The two great primary objects of the board were, to ascertain the general agricultural state of the country, and the means of improving that state. As the most effectual way of accomplishing these objects, agricultural surveys were made; and "in the course of a little more than a year," as stated by a distinguished writer on husbandry, "the board of agriculture had printed a body of authentic facts respecting the agricultural and internal economy of the country, greater than was ever obtained by any other nation since the beginning of time."

But these works, amounting to about eighty volumes, were too voluminous for general use; and the next object of the worthy president was to condense, and bring within the compass of a volume, all the most material facts thus collected, in order to render them available to the practical farmer, and more conducive to general improvement. He laid it down as a maxim in literature, that "knowledge, previous to its being brought into a condensed state, may be compared to a small portion of gold, dispersed throughout a great quantity of ore. In that rude condition, the strongest man cannot sustain its weight, nor convey it to a distance; but when the pure metal is separated from the dross, a child may carry it without difficulty."

In his address to the board, in 1813, he remarked, "that the power and prosperity of a country depend on the diffusion of useful knowledge, can hardly be questioned; *and there is probably no art in regard to which a variety of knowledge is more essentially important, than in the art of agriculture.* The extent of information necessary to bring it to any thing like perfection, is hardly to be credited. To preserve the fertility of the soil—to free it from superfluous moisture—to cultivate it to the greatest advantage—to raise its productions at the least expense—to procure the best instruments of husbandry—to select the stock likely to be the most profitable—to feed them in the most judicious manner, and to bring them to the most advantageous markets—to secure the harvest even in the most unpropitious seasons—to separate the grain from the straw with the most economy and success—and an endless variety of other particulars, require a degree of knowledge, *to do them well*, of no common description."

It is said that Sinclair was first induced to direct his attention to a digest or code of agriculture, by a suggestion of Sir Joseph Banks, "that an account of the systems of husbandry adopted in the more improved districts of Scotland, would be of the greatest advantage to the agricultural interests of the United Kingdom: and that it was incumbent upon a native of Scotland, while presiding at the board of agriculture, and possessing all the means of information which that situation afforded, to undertake the task. In objection, Sir John argued, that the labor of accomplishing such a task, would be very great—that it would be extremely difficult to obtain such information, and that it would afford cavillers an opportunity to attack the board, on the grounds of promulgating doctrines which, if acted on, might prove ruinous to many farmers."* But all obstacles vanished, when Sir Joseph further urged, "that agriculture has derived, is deriving, and will derive, more benefit from Scottish industry and skill, than has been accumulated since the days when Adam first wielded the spade." This was in 1809. Sir John immediately set about collecting and arranging the materials for his Code of Agriculture. He opened a correspondence with the most eminent men and best practical farmers; made three or four tours upon the continent, to acquire a knowledge of the improvements there, particularly in Flanders and Holland, of which he published accounts; and he also published a Code of Health, adapted to the various conditions of life. He was mainly instrumental in promulgating the knowledge of Elkinson's system of draining, and of its being extensively adopted; in inducing Davy to undertake his valuable work upon agricultural chemistry; in instituting and giving efficacy to the Highland Agricultural Society; and in introducing to public notice McAdams' improved system of road making. So late as 1815, the latter was first put into effectual practice, by the Bristol District of roads; and such was found to be its great utility, that now most of the principal roads in Great Britain have been reconstructed upon this admirable plan. He also published, after his Code of Agriculture had passed through the press, a Code of Statistical Philosophy, a Code of Finance, and had nearly prepared for publication a Code or Digest of Religion. "We are informed," says his biographer, "that in his introduction to the proposed code, the writer proceeds upon the supposition that he had undertaken the instruction of an individual, who was either altogether unacquainted with revealed religion, or who had imbibed very limited or erroneous views concerning it. The pupil is led through a system of progressive instruction. He is presented with a general view of human nature, comprehending, first, the corporeal frame, and, secondly, the mental faculties of man—then, with an account of the globe, where the Creator has placed him—then, with that of the heavenly bodies, by which the earth is encompassed. Rising from nature, up to nature's God, it was next intended, reverentially, to contemplate the being and attributes of Him by whom all things were made, and through whom all things live, move and have their existence. It was then intended to inquire, whether any revelation of the Divine will had ever been made to the human race, and, if so, where the best account of that revelation was to be found. It was intended that the work should conclude with an examination and explanation of the precepts and doctrines thus promulgated to man, to guide him in his conduct here, and lead him to the enjoyment of the promised happiness hereafter. The mass of mankind," to continue our quotations from the work before us, "who are misled by the tinsel of military glory, the superficial glitter of eloquence, or the accumulation of great wealth, are incapable of appreciating the silent effects of social improvements; but we confess, that if it were in our choice to select the path of glory, which wisdom and the better experience of mankind will consecrate, we should prefer the distinctions arising from the useful and unequivocal career of a Sinclair, to any renown attached to the splendid achievements of a Bonaparte, the fascinating eloquence of a Pitt, or the unmeasured wealth of a Baring."

In regard to the Code of Agriculture, as many of our readers cannot have had an opportunity of seeing it, we copy from the Quarterly Journal of Agriculture, a brief notice of its contents and arrangement, as useful to every class of farmers, in suggesting the points and the order in which the prominent matters in farming should engage their attention.

"The first section of the Code of Agriculture is devoted to the consideration of the preliminary points which a farmer should ascertain, before setting himself down to the cultivation of any considerable extent of land, particularly climate, soil, subsoil, elevation, aspect, situation, tenure, (whether in property or on lease,) rent, assessments on, and size of farm. In the second section, inquiry is made regarding the means essential to secure niceness in farming, namely, capital, regular accounts, arrangement of agricultural labor, farm servants, labors in husbandry, live stock, implements, agricultural buildings, command of water, divisions of fields and farm roads. In the third, the various modes of improving land are pointed out, by cultivating wastes, enclosing, draining, manuring, paring and burning, fallowing, weeding, irrigating, flooding, warping and embanking land. The fourth section is devoted to the explanation of the various modes of occupying land, in arable culture, in grass, (including the dairy husbandry,) gardens and orchards, woods and plantations. And the fifth, which concludes the work, is occupied in a general consideration of the means for improving a country, the diffusion of information, the removing of obstacles to improvment, and by positive encouragement [by government.] In the body of the work, only general principles are discussed, and where minute information is necessary, it is inserted in the form of foot-notes; while points requiring further explanation or detail have separate papers devoted to them in the appendix. The Code of Agriculture, by Sir John Sinclair, must ever be regarded as the standard work on the state of that science—for he has raised it to the dignity of a science, by establishing its principles —especially as referring to the commencement of the 19th century. It is a monument honorable alike to his ingenuity, his untired perseverance and his general philanthropy. His mind was impressed with the belief, that the prosperity of the human race in a boundless measure depended on their knowledge of cultivating the soil, or, in other words, increasing the natural means of subsistence; and he reckoned no labor too assiduous, no obstacle insurmountable, when such an object occupied his generous enthusiasm."

---

* We, too, have cavillers, who scout at the idea of improving their practice, by book farming—by the examples of others, who excel in husbandry, and who bring their minds to aid in the improvement of the soil.

Importance of Chemical Knowledge in Husbandry.

"Agriculture," says Sir H. Davy, in one of his lectures, "to which we owe our means of subsistence, is an art intimately connected with chemical science; for although the common soil of the earth will produce vegetable food, yet it can only be made to produce it in the greatest quantity and of the best quality, by methods of cultivation dependant upon scientific principles. The knowledge of the composition of soils, of the food of vegetables, of the modes in which their products must be treated, so as to become fit for the nourishment of animals, is essential to the cultivator of land; and his exertions are profitable and useful to society, in proportion as he is more of a chemical professor.—Since, indeed, the truth has been understood, and since the importance of agriculture has been generally felt, the character of the agriculturist has become more dignified and more refined; no longer a mere machine of labor, he has learned to think and to reason. He is aware of his usefulness to his fellow-men, and he is become at once the friend of nature, and the friend of society. If land be unproductive, and a system of ameliorating it is to be attempted, the sure method of obtaining the object is, by determining the cause of its sterility, which must necessarily depend upon some defects in the constituents of the soil, which may be easily discovered by chemical analysis. Are any of the salts of iron present? they may be decomposed by lime. Is there an excess of silicious sand? the system of improvement must depend on the application of clay and calcareous matter. Is there a defect of calcareous matter? the remedy is obvious. Is an excess of vegetable matter indicated? it may be removed by liming, pareing and burning. Is there a deficiency of vegetable matter? it is to be supplied by manure. In the selection of the remedy, after the discovery of the evil, chemical knowledge is of the highest importance. Limestone varies in its composition, and by its indiscriminate application, we may aggravate the sterility we seek to obviate. Peat earth is an excellent manure, but it may contain such an excess of iron as to be absolutely poisonous to plants. How are such difficulties to be met but by the resources of chemistry? That much vague speculation may be found in the works of those who have lightly taken up agricultural chemistry, it is impossible to deny. It is not uncommon to find a number of changes rung upon a string of technical terms, as oxygen, hydrogen, carbon and azote, as if the science depended upon words rather than upon things. But this is in fact an argument for the necessity of the establishment of just principles of chemistry on the subject. If a person, journeying in the night, wishes to avoid being led astray by the ignus fatuus, the most secure method is to carry a lamp in his own hand."

The Turnip Flea.

Our correspondents make great complaint of the depredations of the turnip flea, and ask us to prescribe a preventive. This insect is in length nearly the eighth of an inch; smooth, shining, and of a brassy black colour, with a slight tinge of green, particularly on the wing cases. This little insect preys upon several species of plants, as cabbages, radishes, but is particularly fond of the turnip, which it attacks both in its perfect and larvæ state. It is principally destructive when the plants are in the seminal, or first leaf, and are tender. When the second leaves are unfolded, and the plants have acquired strength, their depredations are comparatively insignificant upon the leaves, though they continue, in their larvæ state, to prey upon and injure the roots. They are extremely voracious, an individual consuming, as has been ascertained, ten young turnips in a day.—In Britain, where there are from 60 to 100 acres of turnips on a farm, they cause immense losses.—They afford evidence, that there are few pleasures or profits without alloy, and seem to be a means of inciting man to constant healthful industry and vigilance.

There have been many receipts published as a preventive of the evils inflicted by this pigmy enemy of our crops; but hitherto all seem to have failed of producing the desired effect. Among other applications to the seed, oil, brine and sulphur have been used, sometimes with apparent success; and one farmer completely saved his crops for fifteen years, by keeping the seed sometime previous to sowing, among a quantity of flour of sulphur, and sowing the sulphur along with the seed. In this way the juices of the plant might be tainted by absorption, so that the insect had no relish for it.

The best remedies for the evil seem to be:

1. To have the ground well prepared and rich, so as to insure a vigorous growth to the young plants.

2. To sow thick, that a part may at least have a chance to escape the flea,—and the crop being thinned at the first hoeing. And it has been found effectual to sow thick an extra row between every two rows intended for the crop—the thick sown being more tender, are preferred by the flea, and may be extirpated by the cultivator at the first dressing,—the extra seed and labor bearing no proportion to the value of the crop.

3. And principally, reliance must be had, when the young plants are threatened, on dusting the plants with some kind of powder. Soot, ashes, gypsum, &c. have been used for this purpose, "but there can be no doubt," says the Quarterly, "that by far the most useful application of this kind is quick-lime."

The Doncaster Agricultural Association, which has rendered the most essential service to the agricultural world by its labors and publications, has given to this subject the best attention; and has concentrated, by their queries, the experience and improvements of more than one hundred practical farmers, on the means of averting the evils induced by the turnip flea. From this information, they have prescribed certain rules of prevention, from which we take the following, as particularly adapted to our practice:

"Most effectually to insure the speedy growth of the plant, the land should be kept in the best possible state of cultivation.

"The system of ridging the land, with manure under the rows, and drilling on the ridges, should be adopted in every possible case.

"The most favorable opportunity for ridging should be chosen, and it ought to be particularly observed, that the land be not ridged in too dry a state.

"As soon as the land is opened for manure, it ought to be laid in, the ridges formed, and the seed drilled immediately. The quicker these operations follow each other, the greater chance there is of a good crop.

"The manure chosen should be adapted to the soil, and such as is likely to insure the speedy growth of the young plant, and a full quantity ought to be allowed.

"The seed should not be deposited in the manure, but the manure thinly covered with soil, and the seed drilled in this soil.

"A very liberal allowance of seed ought to be given, as much as 3 lbs. or 4 lbs. the acre for drill, and 6 lbs. or 7 lbs. for broadcast, and the seed should be of one year's growth.

"As soon as the plant appears above ground, it should be dusted with quick-lime, and this repeated as often as rain or wind beats it off, and the fly reappears."

We will only add, that we spread our manure, drill upon the level surface, and, in eighteen years' practice, have never made any topical application, and yet have never failed in obtaining a fair crop of turnips.

Mildew on the Gooseberry.

At page 59, of our last volume, we mentioned our success in *arresting* the progress of the mildew on our gooseberries, by sprinkling the bushes with a weak pickle; and in page 159, we stated the Rev. Mr. Reed's mode of preventing the blight in pear trees, by impregnating the soil with iron, and his suggestion that salt would prevent the mildew on the gooseberry and the grape. We applied the blacksmith's cinders to a part of our pear trees, and tan to another portion; and there is yet no appearance of blight on either. In February we had the ground about our gooseberry bushes well saturated with strong pickle, and our gooseberries are perfectly free from mildew, for the first time in twelve years. It is not yet time to determine upon the efficacy of the pickle on the grape vines. We infer from the facts that have fallen under our notice, that the mildew is an abiding parasite, particularly at the collar and at the roots of the gooseberry and grape; that the minute seeds of this parasite are wafted to the fruit in a certain state of the atmosphere, and that salt destroys the vitality of the prolific parent in the soil. See No. 10, vol. iv. We beg here to observe, that we err here as in the most other kinds of fruit, in esteeming the *largest* as the *best* varieties. The large gooseberry has generally a thick tough skin, while the best, and they are generally of a medium size, have a thin smooth skin, indicative, also, of good flavor.

We overlook the Main Point.

Did our politicians, including, of course, the honorable members of our legislatures, display half the zeal, and expend a tithe of the money, to enlighten and encourage agriculture, and to render the earth more prolific in the bounties of Providence, that they display and expend in the scramble for power—for the spoils of office—which many grasp at but few obtain—we should have less complaint of hard times; and we should become, what we too vauntingly boast of being already, an independent, a prosperous and happy people. There would then soon be but little occasion for young lawyers and boys running about to instruct our sturdy farmers in their interests and political duties. He is not a *wise* man who does not know *how* to vote—nor a FREE MAN who *dares* not vote as he thinks right—nor a PATRIOT who *will* not do so.

Sale of Mr. Weddle's Cattle.

In our advertising sheet for February, was noticed the intended sale of a fine stock of cattle at Bloomfield, the property of Mr. Thomas Weddle. Twelve cows and heifers sold for $4,133—averaging $344 each, and some selling as high as $500 and $520. Nine bulls sold for $3,437, averaging $382—two of them bringing $600 each. Three cows and their calves for the three last years, sold for $1,690, $1,584 and $1,642. The highest priced animals, and we presume the best, were generally bought by Gen. Dudley, of Kentucky.

Hints on Pruning Forest Trees.

There were five competitors for the Highland Society's ten guinea premium, offered for the best essay on the pruning of forest trees,—a business which, to be sure, is not yet much practised among us; but as many of the principles which govern in the operation, apply in the pruning of fruit and ornamental trees, we shall state some of them. The essays are not published entire, but a digest of them is given by William Scott, one of the directors, who states, that on all the leading points, except as to the time of pruning, there is almost a perfect coincidence of opinion expressed in them all.

1. *Is pruning beneficial?* "Although pruning in ordinary cases does not ultimately increase the weight or bulk of wood, yet trees which are *early* and *judiciously* pruned, will be improved in quality, increased in their useful dimensions and ultimate value, and a greater number can be grown on a given space."

2. *Thinning the plants*, as they advance in growth, is deemed indispensable.

3. *Pruning should be begun early*, and the directions for pruning, coming as they mostly do from professional nurserymen, are worth remembering:—"When trees in the plantation have produced three, or very thriving two years growth, pruning should be commenced. At this period the knife is the most suitable instrument, and the *top* is the principal part of the plant which requires attention. In order that only one shoot may be allowed to remain as a leader, the others next in size, if not very inferior, should be headed down, generally to about one-half the length, and all the stout lateral branches of the tree headed in the same manner. No such branches need be cut close to the stem at the first, second, or third pruning." "All suckers or branches that spring from the roots, which tend to make the plant more like a bush than a tree, should be taken away."

4. *Error to be avoided.* The practice of cutting away the side branches to a certain height, at the first pruning, and afterwards to operate only on the under branches of the tree, is reprobated, as tending to produce a small trunk, an irregular top, and side-branches more vigorous than the leader. Under this management, in "exposed places, not one in a hundred ever becomes a large and valuable tree."—"Such an excess of amputation destroys the health of the tree, by depriving it of the organs by which a sufficiency of sap is secured [elaborated] to be afterwards converted into wood."

5. The leading shoot should be preserved, and all others checked which have a tendency to compete with it, so as to divide the stem into forks or clefts.

6. "The writers agree in opinion," says Mr. Scott, "that young trees should not be pruned at once close to the stem, but that the larger branches which it may be necessary to cut away, should be shortened first, and cut close afterwards." As decidious trees give out an irregular tier of branches yearly, any branch should be shortened which is of greater length than the majority of those on the same tier; or, if the whole of them be too long, they must be shortened. By the concentration of the sap, which the shortening effects, a much greater quantity is thrown into the main stem," the leaves are much larger, the foliage healthier, and the tree shoots up much faster, and at the same time maintains a proportional circumference of stem.

The objects of the pruner should be "to give, in trees of advanced size, twice the length of the trunk to that of the top, in good soil; and in poor soil to leave the top as long as the trunk; and 2d. to have one inch in circumference to 15 feet of height; and if the circumference is proportionably greater, so much the better."

With regard to coniferous trees, as the silver fir, spruce, pines, &c. it is objected to their being pruned, *in any soil or situation.*

The opinions of the writers as to the best season of pruning are variant. One recommends April to June; another before the buds swell; another in autumn, &c. and Mr. Scott, to reconcile the contradictory opinions, proposes to prune "a little before the buds begin to swell,—or a little while after the leaves have expanded." We repeat—late in June.

Farming Implements.

The improvements which have been made in the implements of husbandry, in the last thirty years, and the introduction of new implements, have not only tended greatly to abridge manual labor, but, by doing the work much better than it was formerly done, have increased much the bounties of the soil. Having the desired implements, the next object is to learn to use them with facility and skill, a task more difficult in acquiring than many seem to imagine. Take, for instance, the plough, the most common implement of husbandry, and we venture to say, that not one in fifty who uses it, knows how to use it as well as he might do; or, knowing, does use it as he ought to do. But not only have the implements long in use been improved in their model and fabrication, but new ones are coming daily into more general use, as cultivators, drilling machines, rollers, straw cutters, hay rakes, mowing machines, root-slicers, potato hooks, turnip hoes, &c. which greatly aid in the economy of the farm. It has been our object to note such of these as came under our notice, and to commend them so far as our observation and experience would justify. This we shall continue to do, in the belief that they are calculated to facilitate greatly the labors of the farm, and to increase its products and profits.

We in the first place invite the reader's attention to the *Potato Raiser*, of the Messrs. Lawsons, of Edinburgh, figured and described in the present number. The potato is extensively and profitably cultivated among us, and its culture is likely to increase. It is an excellent crop to ameliorate and cleanse the ground—to convert long into short manure, and thus fit it for small grains, and no less excellent for stock and the market. Under the improved mode of management, it may be planted and receive its after culture, almost exclusively, with the plough, harrow and cultivator, with but little aid from the hand-hoe. The great expense is in harvesting the crop. If this can be lessened, and the Messrs. Lawsons and Capt. Center assure us it can be greatly, by a potato plough, like the one described, the culture of this valuable crop may be profitably enlarged. The expense of procuring a potato raiser, or a potato mould-board, and fitting it to a common plough, will be trivial, compared to the advantages which are likely to accrue from its use.

Hoyt's Drill Barrow is also figured and described in the present number. We have not had it in operation; but from examining the principles upon which it works, we give full credit to the declarations of the patentee. The cost is about $10, and it is said to be adapted to the sowing of all kinds of seeds.

Bushnell's Drill Barrow.—We have had this in operation, and it justifies the high expectation we expressed of its value. It differs from any we have seen in this: the forward wheel pulverizes and levels the surface, and thus enables the workman to graduate the coulter, while the after wheel breaks and presses upon the seed the earth which is thrown upon it by the brush or rake which is applied behind the hopper. This machine drops four to eight turnip seeds, at intervals of about eight inches; and it has slides adapted to seeds of all sizes, which may be used at pleasure. These slides are of tin. They ought to be of wrought iron, like those in Merchant's drill, which latter, by the bye, suffers nothing in reputation or value, by being better known. A Scotch farmer, familiar with the drill barrows of his native country, and who has used Bushnell's, pronounces it the best he ever tried. Ample reference to the patentee and venders, will be found in our back numbers.

Mr. Thorp has improved his *Turnip Hoe*, by making the shank, which connects the cutting part with the eye, stronger and of better iron, and by using better copper rivets than heretofore. This hoe is worthy the attention of every turnip raiser, and of every gentleman who takes exercise with a hoe in his garden.

Potato Hooks.—Several models of these have been sent us. They are all useful and serviceable in many operations of the farm and garden. In culture, they effect an important purpose—they loosen the surface to any reasonable required depth, pulverize it, and render it pervious to atmospheric and solar influence, as well as free it of weeds. It is excellent in raising potatoes and turnips. A new one has just been presented to us by Messrs. Ripley & Spalding, the manufacturers, residing at Norwich, Ct. They are for sale by our neighbor Thorburn, at 50 cents.

Root Slicer.—We have received one from Mr. D. M. Walker, of Whiting, Vt. As our turnips were mostly fed out when it came to hand, we had not a fair opportunity of trying it; but we did experiment upon it so far as to ascertain, that it would not only slice, but cut into inch strips, a bushel of ruta baga in a minute, turned by a smart man. This machine was noticed and described in the last number of vol. iv. It is not patented. The iron work costs about $6. The wood work may be made by any carpenter, or an ingenious farmer. If Mr. Walker will renew his request, his letter having been mislaid, it shall be promptly attended to. We should advise that the knives and cutters be reduced one-half, in this machine. It will still perform its work expeditiously, and be less fatiguing to the operator.

Van Bergen's Cultivator.—We have used this implement, the present season, in cultivating our hoed crops, and think it has a decided preference over the old triangular drill, though we have had no opportunity of comparing it with Bement's. The side pieces are parallel with the centre one, and each of the former has a forward coulter to cut the weeds and pulverize the soil, and a coulter with a small mouldboard in rear, to gather the loosened earth in the space between the rows, or to throw it to the plants. The implement may be contracted or expanded at pleasure, or the laterals may be taken off, and the centre coulters used among beans, or other crops, where the drills are 12 or 18 inches asunder. In the first dressing of our corn, potatoes, &c. the loose earth was turned from the hills. The plants were then cleaned with the hoe, and when necessary, thinned, and the cultivator soon after followed, turning it to the rows, and giving the plants a slight earthing. In the potato crop, the small plough follows the cultivator, to give a slight, but the only earthing it receives. The cultivator may be advantageously used a third or even a fourth time, in the corn crop: it keeps the surface mellow and clean. We can with confidence recommend this implement, for all lands not encumbered with large stones or stumps. The fault in this machine, if any, is the weakness of the wood-work, and of the cast-iron teeth, which are liable to be broken if they are brought in contact with stout roots, or immovable stones. Our machine has suffered in this way.

The operation of Bone Dust.

Bones are a phosphate of lime, that is, they are composed chiefly of lime and phosphoric acid. When crushed, and deposited in the earth, by the action of heat and moisture, the bones are soon reduced to a state of decomposition, and the original elements of which they are composed are thereby set at liberty to form new combinations in the great circle of revolving nature. By this means, the phosphoric acid is set free in the form of gas, and the lime is left in its caustic state, deprived of its neutralizing acid; these two substances are then left to produce the powerful vegetation which we see to follow their application as manure in their new state; and as we know of but few principles in nature more powerfully active than phosphorus, in all its states of existence, we have formed the idea, that phosphorus, in conjunction with the lime, perhaps in the state of phosphoric acid gas, is the chief cause of the rapid and luxuriant vegetation produced by the application of bruised bones as a manure. The phosphorus of our shops is so easily ignited, that the least friction sets it on fire; nay, if exposed to the air, it burns spontaneously by a slow combustion, and therefore can only be preserved from combustion by being immersed in a vial of water; hence I consider that crushed bones evolve a considerable quantity of gas and heat during decomposition in the earth. As I have attempted, in a field of my own, to try some experiments with the bone dust, I shall, with all deference, state the results. 1. I find that old rotten bones, and dry bones, crushed properly, work sooner, and are more readily efficient as a manure, than fresh or green bones; the latter requiring a longer space of time to decompose and part with their phosphoric principle than old bones, already partly in a state of decomposition.* 2. I find that bone dust acts most readily and powerfully, if, the night previous to its being put into the earth, it be formed into a heap, and thoroughly wet,† and allowed to lie till it is beginning to become warm. It then ought to be put (in its wet state,) into the ground, when a powerful and luxuriant vegetation immediately follows. In a dry soil, it remains long before decomposition, and also in very wet ground. This may account for what, to a certain extent, by some has been considered a partial failure of its usual effects.—*Aberdeen Journal.*

A Hint to Cattle Breeders.

T. A. Knight, the very distinguished horticulturist, publishes in the Farmers' Magazine, a communication on the ill effects of overfeeding young stock. Young cattle thus brought up, when taken into other districts, have been found, with their offspring, incapable of thriving upon common pastures. Animals, he thinks, which have been overfed from their birth, and whose ancestry have been subjected to the same treatment, acquire a power of eating and digesting a much larger portion of food than others. He admits that the improved Durhams are brought to market at a very early age, oxen of very great weight and excellence; yet he says it is well known that all those young animals come to market deeply insolvent, the sums for which they are sold being greatly less than those expended in feeding them. In illustration of their expensive keep, he cites the following facts:

"Three Herefords and three Durhams," says he, "were put into stalls, to be fatted, on the 3d of November. The weight of the Herefords was then 33 cwt. and that of the Durhams 38 cwt. and 14 lbs. Between that period and the 30th March, when all were sold in Smithfield, the Durhams consumed 12,755 lbs. weight more of turnips, and 1,714 more pounds of hay, than the Hereford; but the Durhams, notwithstanding the larger size when put to fatten, and the greatly larger quantity of food consumed, sold for only 20 shillings more than the Herefords; and such I believe will ever be the result of similar trials, when one class of animals has been properly fed, and the other over fed, the merits of the breed being equal."

This reasoning is true in regard to perennial vegetables—trees for instance. If the nursery from which they are drawn, and in which they have been raised, is very rich, they will not thrive so well in a common soil, as those which are taken from a soil of an inferior quality. If the habit of gormandizing is established when the plant or animal is young, neither will thrive so well afterwards upon spare food, as if they have been brought upon more moderate fare.

South Down Sheep.

"My chief reasons for preferring this breed," writes Mr. H. Watson, "are:—that the South down sheep, although an active and spirited animal, are easily controlled and managed by a good shepherd—can go over more ground for food than any other kind of sheep, without stopping their growth,—and when tried by severe storms in winter, will brave it better than even the black-faced Highland,—and although reduced very low in spring, sooner pick up condition, than the other short woolled sheep. As a proof of the Southdown's inclination to fatten, when put to good keep, I may mention a fact, that while I have seldom been able to produce a fat Cheviot sheep the same season she has reared a lamb, I never fail to make good fat of the South downs *off grass.* Their wool is so closely matted on their backs, and about the head and neck, as to be almost impervious to rain or snow; hence, so soon as the storm ceases, they appear dry and comfortable, their coat not the least disordered, and altogether free from that drenched appearance which longer woolled sheep exhibit, even for days, after a winter storm."

Mr. Watson says the South downs are remarkably healthy; that his loss in them has invariably been much under that of any other sheep he has bred; that when crossed with a well-bred Leicester ram, and brought into good keep, they produce the most profitable lamb that is bred; that the wool fetches the highest price of any British wool; and that he has realized from them, when 16 months' old, not less than 40s. ($8.88) each, wool and mutton. But mark! Mr. W. gives this preference over every other sheep, for districts "*too high to be occupied during the whole season by a flock of Leicesters* (Bakewell) *and under that level which the native* (Scotch) *sheep* only *can thrive upon.*"

ON AN AGRICULTURAL EDUCATION OF GENTLEMEN FARMERS, AND THE SCIENTIFIC EDUCATION OF PRACTICAL ONES.

Men are prone to become idle as they grow wealthy; but if they have been early imbued in the practical knowledge of their business—say, for instance, have been brought up at the counter, or on the farm, their early habits, and the practical knowledge acquired in youth, are of invaluable service to them in more advanced age, though they do not submit to manual labor—in superintending and directing their affairs. It is a kind of knowledge which no man can get rid of, if he will, but it will intrude upon his mind, and guide his judgment, in after life. The theory will not do alone. The head may teach the hands *what* should be done; but the hands must teach the head *how* things should be done. The man who undertakes to direct the operations of a farm, without a practical knowledge of the manipulations and mechanical labors which are to be performed upon it, generally fails in his expectations; and, if he has undertaken it for recreation or for profit, he sinks his capital, or retires from his new employment in disgust, before he has either tasted its pleasures or become capable of judging of its advantages. Whatever be his pretensions to science, there are a multitude of details in farming, which make every thing on the score of economy, which are best learnt in youth, and without a personal and practical knowledge of which, all is guess-work and uncertainty.

---

* Bones may, in this respect, be compared to dung: in a half-rotted state, they work *sooner*, but do not work *so long*—the gases of both, are lost by partial fermentation.

† We have found this process facilitated by blending ashes with the bones.

Nor have we, at present, any institutions where the science can be acquired by young gentlemen, such as will qualify them to manage with judgment and profit, the estates which they are expected to heir, and destined to occupy. In existing schools, the sciences are taught rather as abstract studies, than as auxiliaries to productive labor. It is only by giving demonstrations of their principles, on the farm and in the shop, that we are enabled properly to instil into the minds of youth, their important bearings in the business of life. How little do the graduates of our colleges know, when they come from the classic halls, of the application and importance of the natural sciences, and of chemistry, to the business of the farm. But give them two years of practical instruction, and then scientific acquirements become useful and highly profitable to them. But if the science and practice are blended in the school of instruction, the second apprenticeship is superseded—the two years are saved—and the boy comes into manhood with the highest qualifications, and suitable habits, to distinguish himself for usefulness, either as a laborer or manager on his own estate, or as a valuable assistant to others; and with the knowledge and habits acquired in such a school, there is little danger of his becoming tired of the farm, a drone in the commonwealth, or of his selling his principles, and compromitting the freedom of his country, for the corroding "spoils of office."

The importance of the sciences to all the arts, and more especially to agriculture, is every day becoming more manifest. Scotch husbandry has more of science than that of any other country; and Scotch husbandry has reaped from it the richest rewards. Scotland has progressed in improvement, in the last half century, much faster than any other country. And the improvment of the mind, and the habits and comforts of her population, have advanced with the increased productiveness of her soil. But Scotland has not been alone in efforts to bring the mind as a powerful auxiliary to agricultural labor. The Great Frederick of Prussia, was in the habit of expending more than a million of dollars annually to improve the agriculture of his dominions, which he considered as manure spread upon the ground. France places $100,000 annually at the disposal of one of her ministers, to be employed for a like purpose. Bavaria, Hungary, Wirtemburgh, Prussia, France and Ireland, have their public schools of scientific and practical instruction in agriculture. But we have yet to begin in this work of usefulness—in this work of mental, moral, and we may add political improvement—for, disguise the matter as we will, our security as a free people depends emphatically upon an enlightened and prosperous yeomanry. Half the money that has been expended, or in the opinion of some wasted, in the Seminole war, would have built and endowed an agricultural college in every state of the union; and a tithe of the national expenditure now, over what it was a few years ago, amounting, as it does, to 14 or 15 millions annually, applied to improve and elevate the standing of rural labor, would have added, by this time, at least a tenth to the annual products of our agriculture. It is not our province to find fault with what *has* been done—we wish only to state what *might* have been done.

On the importance of practical and scientific instruction to the higher classes, and of scientific instruction to those of lower grade, we beg to offer the following extracts, which we copy from a lengthy communication on the former branch of this subject, published in the Edinburgh Quarterly Journal of Agriculture, and which have a particular reference to the south and to wealthy farmers of the north, who think their sons cannot become *great* men, without they are sent to the counter, the bar, or the desk, or assume the *dignity* of mere idlers.

"Strange to remark, anxious as landed proprietors certainly are to bestow a liberal education on their families, which is the best legacy they can leave to their younger sons, agriculture, which most materially affects the interests of themselves and their eldest sons, the very profession by which they are upheld in the high stations of society they occupy, they almost entirely neglect, as if, after the acquirement of a superior education, a man should be ashamed of attending to the means of his subsistence. Is it not 'passing strange,' that any country gentleman should be unacquainted with farming, the very source of his livelihood, when all other classes of people, in learning their respective professions, whether learned or vulgar, serve apprenticeships, and toil through life thereafter? It seems to be forgotten that land ownership *is* a profession, that it is in the manner in which *it* is conducted, that the best interests of the country may be injured or promoted, and that it is a profession which requires as great capacity of mind to practise it aright as to conduct those large commercial and manufacturing establishments whose importance is so much lauded."

The writer then proceeds to enumerate the difficulties and losses which result from trusting the business of the farm to factors and agents, most of whom are wholly unqualified for the task; and the pleasurable sensations which are lost to the owner, by not understanding, and feeling a deep interest in, the various operations which are continually going on. He then proceeds—

"Now the effects of all these evils, we venture to assert, may be most effectually remedied by the sons of landed proprietors, who will themselves become land owners, acquiring a thorough knowledge of farming in their youth, as a necessary branch of practical education, and the management of their estates will then be felt a desirable gratification, not a task." "Proprietors would then discover there is not a more rational, pleasing, or interesting study, than the science of agriculture, and its practical application, nor one which can be so well combined with those manly sports and amusements in which it is the pride of our country gentlemen to excel. They would then have no temptation to reside abroad, but would discover, that a knowledge of the minutiæ of farming creates a daily increasing interest in field operations, and the rearing of stock."

"Where is all this important knowledge to be acquired? It is to be acquired, like every other species of knowledge, by observation, in the operation of nature, as displayed in the fields of art. Is this question asked in a country whose proud boast is to possess more enterprising, educated, and well-informed farmers, [a boast that ought to apply literally and most emphatically to our free country,] than perhaps any other country in the world?"

The writer then proceeds to answer the question by recommending, that these sons of wealth, and inheritors of land, spend two years with an intelligent farmer, under the direction of a scientific tutor of competent acquirements. But how much better would be a school, in which there should be a tutor for each of the prominent branches of agricultural science, a first rate practical farmer, a library, an experimental farm, a philosophical apparatus, a mechanical laboratory, a well conducted garden, and the stimulus of competition. But let us attend to what our writer recommends that the tutor should teach:

"He should be competent to teach," says he, "the application of chemistry. He should teach the application of the principles of mechanics, in order that the principle on which any implement operates may be comprehended,—the application of the principles of hydraulics, that the principles of draining, embanking and constructing reservoirs for water, may be easily understood. He should teach botany, to enable young farmers to distinguish soils by their natural vegetation; and particularly the physiology of plants, that the culture of plants of whatever kind, may be in conformity with appropriate soil and situation. Also geology, that the sub-strata, or subsoils, on which soils rest, may obtain due regard. Meteorology should be studied, in order to be able to anticipate the changes of the weather. The anatomy and physiology of animals are also requisite for him to teach, that the good points of live stock may be duly appreciated. And above all, he ought to be acquainted with the *practices* of agriculture, for although the farmer will no doubt undertake to teach this department of the system, yet, unless the tutor also understands it, he cannot so successfully demonstrate the applications of science to the operations of practice."

"With colloquial prelections and discussions in the house at stated hours, so as not to interfere with the hours of labor in the fields, and with demonstrations in the field, whilst the labor was in progress, a vast mass of useful information would in a short time be conveyed to, and acquired by, the pupils."

Practical Effects of Draining.

The system of draining introduced into Scotland some years ago, and proceeding so rapidly, must be regarded as the greatest improvement of modern times. The landlord and farmer do it jointly. Here is a safe investment for money—the expense repaid in twenty years, regular interest, and the land improved in value above one-third. Green crops are grown in great abundance after draining, where no attempt could be made before, and the farmers allow they have four crops in three years, and the draining pays on an average eight per cent. I know an instance of a wet clay soil, almost covered with rushes, being drained and improved at an expense of £15 an acre ($65); the green crops were so productive as to repay the expense in one year, and after deducting the old rent, the improvement pays fourteen per cent upon the outlay. The drains are from 20 to 30 inches deep, and at the distance of from 12 to 20 feet, sometimes in the furrows of the field, or across, or obliquely, as the descent may suit, and sometimes the land is laid flat. Draining, to be remunerative, must be done effectually. A field cannot be drained by putting a drain in a corner, one here and another there; by running one across the field, and another diagonally to that. It must be done completely, or not at all, for half measures are ever useless.—*Qr. Jour. of Ag.*

Draining by Steam.

Joseph Glynn has received the gold medal of the Society of Arts, for a communication on his application of steam power to draining fens, or extensive marshes. The process consists in excavating broad ditches through the fens, and applying stationary steam power at their termination, or lower side, to raise the water to a higher level, that it may pass off. His letter, with the estimates it embraces, is one of great interest to the civil engineer, and augurs favorably to the landed interests. Mr. G. had been employed in eleven districts, and had already drained about 90,000 acres, the value of a portion of which has in consequence been increased from £10 and £20 to £50 and £70 per acre. One tract contained 25,000 acres, and was completely drained and kept dry by two engines of 60 and 80 horse power. An 80 horse power engine, working 12 hours in a day, raised from 19 to 25 millions tons of water in a year.

Deep Ploughing—Treading in Seed.

We gather the following facts, which should not be lost to our readers, and which are in accordance with the teachings of science, from the proceedings of the Rutland (England) Agricultural Association, as published in the Farmers' Magazine.

On Mr. Barker's health being given from the chair, this gentleman returned thanks, stated the great improvement in ploughing, which had resulted from the distribution of premiums, at ploughing matches, and which had amounted to £40, and after referring to other local improvements, he proceeded to say—

"I will detail to you an experiment, which I made last year in deep ploughing. I felt at first inclined to try the press, but some said try the drill, some the broadcast, and at last I selected the drill, and had the seed trodden in by my Lord Lordsdale horses, when they were at exercise, and afterwards had a flock of 400 or 500 sheep driven over it. The produce of this land averaged seven quarters (56 bushels) and one peck an acre throughout 22 acres—(the total product amounting to £402 3s. 9d. (= to $1,785, or $81 the acre,) and from two bushels and one peck of seed per acre sown; and I wish you would try the experiment of treading in the wheat, or fixing it firmly in the ground, which I am sure will lead to a similar result. As regards the exhibition of animals, I think we are still wrong in principle, and in endeavoring to produce so much fat. If we paid greater attention to the increase of *eatable flesh*, I am certain a great improvement might be effected, especially in the quality of Leicestershire sheep and pigs. When our prize animals are killed, what do we find? Why perhaps five or six inches of fat to one of lean. I intend, another year, to offer a premium for that animal which, when dead, shall show the most *lean*, and I hope that some one will offer a similar pig premium. I must beg you to take my hints about fat and lean into consideration, and see whether we cannot produce a greater quantity of *eatable meat* than we have hitherto done."

Useful Memoranda,

From the Farmers' Magazine.

Carrots.—The *Reverend* (for there are clergymen in England who rank among the most enterprising and intelligent farmers,) J. Monkhouse, has raised 30 tons of carrots on an acre. Some of the roots weighed more than 7 lbs. At 2s. per cwt. this crop would be worth £60 (= to $266.40) per acre.

The Blood Red Wheat is said to be uncommonly prolific; and as an evidence of the fact it is stated, that Mr. Wm. Carlishaw obtained from an acre of old cultivated land, 66 bushels of the best, and three bushels of hinder ends—being something more than 23 loads per acre.

Profit on raising good stock.—The stock at Carlton Hall sold as follows:

5 cows, average price..	£68,	equal to	about	$302.
3 2 year old heifers,......	21,	"	"	90.
5 one year old do	19,	"	"	84.
5 heifer calves,..........	13,	"	"	57.
3 bulls,..................	15,	"	"	65.
3 bull calves,............	16,	"	"	69.

Thus 24 cattle brought $2,900. What would 24 common like aged animals have brought? Not $300.

Convertible Husbandry.

The convertible system is nothing more than the application of capital and labor to cultivation under a different system; and the difference between the mode of agriculture, practised in North and South Britain, lies in the method of that application. Under the convertible system, every field has its regular alternate share of cropping and manuring. In England,* one part of the farm is kept in grass, and must on no account be ploughed, the other pays best by being ploughed and cropped perpetually.—The one farmer drains wet lands, and adopts every improvement any way calculated to advance his purpose, the other rejects any alteration on certain established modes of proceeding which must not be altered; the one spares neither labor nor expense in increasing the produce, the other will make no expenditure, under the belief that any other mode of farming than his own will not pay.—*Farm. Mag.*

---

* Although the English system of farming is extolled among us, yet in some districts the management is bad; and in all districts, perhaps, excepting Norfolk, inferior to what it is in Scotland.

Agriculture in France.

There is at present in France 123 agricultural societies, and 303 agricultural committees, where before 1803, there were scarcely ten, and they are constantly increasing. Every thing has been done by the present government to encourage agriculture in a pecuniary way, as well as by the different societies. The sum of 500,000 francs—nearly 100,000 dollars—has been placed at the disposal of the French minister of public works, for the encouragement of agriculture during the year 1838. There have been also several gentlemen travelling in Scotland, at the expense of the French Society of Agriculture, in order to examine the system of farming in that country.

Cheese from Potatoes.

Cheese of extremely fine quality is said to be made in Thuringia and Saxony as follows: Boil a quantity of potatoes, white ones are preferable, and after becoming cool, peel and reduce them to pulp, either by means of a grater or mortar. To 5 pounds of this pulp, which ought to be as equal as possible, add a pound of sour milk, and the necessary quantity of salt. The whole is kneaded together, and the mixture covered up and allowed to lie three or four days, according to the season. At the end of this time it is kneaded anew, and the cheeses are placed in little baskets, when the superfluous moisture is allowed to escape. They are then allowed to dry in the shade, and placed in layers in large pots and vessels, where they must remain for 15 days. The older these cheeses are the more their quality improves. A better kind is made in the same way, by mixing four parts of potatoes with two of curdled milk; and a still better kind, by blending two of potato and four parts of milk.

Useful Tables for Reference.

AN ACRE OF LAND CONTAINS

4	Roods, each rood 40 rods, poles or perches.
160	Rods, $16\frac{1}{2}$ feet each.
4,840	Square yards, 9 feet each.
43,560	Square feet, 144 inches.
174,240	Squares of 6 inches each, 36 inches.
6,272,640	Inches, or squares of one inch each.

Breadths and Lengths of an Acre, in rods and perches and feet.

New Laborers in the Field.

We have received two numbers of the *American Silk Grower*, devoted to the Silk Business, and to Rural Improvement generally, published at Burlington, N. J. by Ward Cheeney and Brothers, a well executed sheet of eight pages, published monthly, at fifty cents per ann. Also, the *American Journal of Productive Industry*, devoted to Agriculture and the Mechanic Arts, an 8vo. sheet of 16 pages, published semi-monthy, at two dollars a year, at Maryville, Te. and conducted by Mr. M'Tew. We hail these as co-laborers in the work of usefulness, and wish them a liberal patronage. We think well of Mr. Cheeney and Mr. M'Tew's abilities, and hope much good from their labors in the public vineyard.

And last, though not least in our estimation, we notice the receipt of two numbers of a recently commenced periodical work, called "*The Educator.*" It comes to us from Easton, Penn.—is printed semi-monthly on a sheet of 8 quarto pages, at $1 per ann.—and is conducted by the president and two of the professors of Lafaytte college; the first, Mr. Junkin, we believe, an American; the second, Mr. Cunningham, a Scotchman; and the third, Mr. Schmidt, a German,—all gentlemen of high literary standing, and, if we are to judge from the specimens before us, of strong minds and correct modes of thinking. Their objects, are to improve the mind and the soil—ours to improve soil and the mind. Our objects are so similar, in the end, that we hail this publication with a heartfelt pleasure, as a powerful and efficient auxiliary in the work of general improvement, and heartily commend it to the notice and patronage of all who are desirous of seeing our country blessed with an intelligent, a moral, a prosperous and an independent yeomanry. We intend, in our next, to give an extract from this work, as an evidence of the talents of those who conduct it, and of its tendency to promote the best interests of the American republic.

HOFFWYL AGRICULTURAL SCHOOL.—An American who has recently travelled in Europe, paid a visit, which afforded him high gratification, to M. Fellenburgh's school, in Switzerland. He saw there a student from New-York city, who informed him that there were several other boys in the school from the same place. "There were pupils on the ground," he adds "from Switzerland, Germany, France, Spain, Portugal, North and South America, and two from Tifflis." When shall we become wise and imitate the good, as we are ever ready to do the bad examples of our European ancestry. When shall *we* establish schools of scientific and practical agriculture for our sons? Whenever their importance shall be duly appreciated—and our citizens consult their true interests in endeavoring to promote the best interests of their country—of their whole country.

To Correspondents.

Some of our correspondents seem disposed to overrate our professional knowledge; and put to us questions which we either cannot answer, or which would require too much time and space to do in a satisfactory manner; and there are others who question us upon matters which have been already repeatedly and fully discussed in the Cultivator. We have received several specimens of soils and earths, supposed to contain marl or carbonate of lime, with requests to give their analyses, and to direct the mode of management and application. We have no chemical laboratory. The expense of procuring an analysis, in the many cases which present, would be heavy, without producing a corresponding benefit to the public—as marls and soils vary much in their relative qualities; and, besides, we possess no other scientific knowledge than any young or middle aged man may soon acquire by reading and observation—without the aid of schools. It is in agriculture as it is in the other arts—the head must work as well as the hands. We must put in requisition the faculties of the mind. We must read, reflect, analyze, compare, and try, what comes recommended to us as established truths; otherwise we cannot expect to derive that advantage from the study and labor of others which lies within our reach. It is the province of the hands to perform, and of the head to direct when and how to perform. Our schooling was very limited. We were brought up to a mechanical profession; and when, twenty years ago, we commenced farming, we were conscious we had every thing to learn, both in the theory and practice of husbandry. Our theatre of action was an unsubdued pine barren, by many considered incapable of profitable cultivation. Yet with great facilities for obtaining extra manure, our farm is under as profitable culture, in proportion to its size, as any in the vicinage, or, we believe, in the county. Our knowledge in farming has thus been acquired at an advanced period of life, by combining book farming with practical farming—the science with the art—and by adopting after close observation and a fair trial, whatever we found to be excellent in the practice and recommendation of others. We sought to profit by the suggestions of our own mind as well as by the labors of other men.

We have thus laid ourselves open to the charge of egotism, in order to show, that it is in the power of the young—of ALL—to become competent judges of the proper means of improving their farms and their fortunes, and of thereby enlarging the sphere of their enjoyments. The principles of science have a general application; yet the judicious application of these principles to practice depends upon a great many local contingencies which practice and observation can alone detect and modify. It is impossible, therefore, to judge of the defects of a soil, or the best means of improving it, without seeing, analyzing or experimenting upon it. The occupant is, or may be, or should be, the best physician. By keeping a journal of the operations of the farm—of the expense and products of the several crops and fields—the manures applied, &c. and by posting these annually into a ledger, to the several compartments of the farm, the farmer can, at any time, bring into view, the relative profits of his several crops and courses of crops—and can judge satisfactorily of the deterioration or increased productiveness of his soil. These accounts are as essential to the farmer as they are to the merchant or mechanic, and may be as easily so kept, that the farmer may, at the end of each year, know the profit or loss of his business, or of any branch of it.

We will, in our next, suggest some rules that shall have a general application, and which will enable the novice to judge of the composition of his soil,—of its defects, and the modes of improving it—and of the means of increasing and perpetuating fertility, by manures, the alternation of crops, draining, &c.

We offer the foregoing remarks, not to complain of those who interrogate us upon matters of husbandry—for we consider a desire for knowledge commendable, and the first step to improvement—but as an apology for the summary manner in which we have answered many of their interrogatories, and for our total neglect to answer others;—and to induce our correspondents to rely more upon the resources of their own minds, and the suggestions of their own experience. Agriculture is a business in which a man may continue to learn as long as he lives, even should his life be prolonged for centuries; and the more a man knows, the less vain is he of his knowledge; because, as he advances, the wonders of nature so accumulate upon his vision, and the means of improvement become so multiplied, that he is wonder-struck and humbled at his comparative ignorance. Knowledge is not the ultimate object of education; but it is the application of it to the useful purposes of life—to the advancement of public virtue and general happiness, that renders its attainment valuable. The man who thinks he can learn nothing in husbandry, must be a dolt, that is, according to Webster's definition, "a heavy, stupid fellow; a blockhead; a thick skull."

With these preliminary remarks, we proceed to notice several letters, in the order in which they lay before us.

EVIDENCE OF THE CORN CROP.

Mr. D. M'Neil, of Morefield, Va. advises, that he will be a competitor for our corn premium, and wishes to know what evidence we require of the product? We answer, his certificate of the fact, with that of a magistrate, that he is a man of veracity, and that his statement is to be depended on. Mr. M'Neil writes us a good letter, which evinces much zeal in a good cause. *A copy of the Cultivator will be furnished to the agricultural society of the Valley,* (South Branch,) AND TO EVERY OTHER AGRICULTURAL SOCIETY IN THE UNION, GRATIS—*on the application, post-paid, of the President of said society, accompanied with the assurance, that an agricultural exhibition has been held by said society during the preceding year, at which at least three hundred dollars have been distributed in premiums.*

CATTLE, PIGS, SHEEP, &c.

We have a letter of inquiry from R. G. Underhill, of New-York, in relation to pigs, one from P. St. George Ambler, of Va. in regard to the improved Short Horns, New-Leicester Sheep, &c. and several other letters in relation to stock. In the stock business we make no pretensions to proficiency. We are not breeders. Of course all we can say must be guess-work, or the opinions of better judges in these matters. In regard to "pigs for orchards," or any other mode of fattening, we can say the Berkshires are *good*, though we do not mean to say they are *the best.* As to the Short Horns, we have requested that Mr. Ambler be advised, and he may depend upon the facts which Mr. B. shall give him. In regard to the New-Leicesters among us, the pure blood are pretty much alike: the difference consists principally in the attention which has been paid to their breeding and keep, and to the selection of individual animals. The price of Mr. Bement's pigs has been stated in our present vol. by Mr. Bement; and the price of New-Leicester bucks may vary from $15 to $50, according to quality. This last remark is also in reply to the letter of G. H. Maccary, of West-Poultney, Vt. Thomas Dunn, of Albany, has as good as any, if not the best New-Leicester flock.

A VERMONT FARMER asks us many questions. We refer him to our preliminary remarks, and to our present and back numbers, for answers to such as relate to the turnip fly, to charlock, the spiked roller, to the culture of potatoes, to farm accounts, &c. His 250 acre beaver meadow, which he represents as dry and yet infested with sedgy grass, should be broken up, cropped, thoroughly subdued, and then stocked with timothy and other grass seeds. Sawdust is good for nothing as a manure till it rots, and is not worth much then. The name of a writer, however humble, will ever command more attention from us than an anonymous signature. No man should be ashamed of a desire to be better informed in his business.

MARYLAND FARMING.

We are not sufficiently acquainted with the farming practices in Maryland, to venture to direct "A Young Enquirer" how to manage his estate, which he advises us consists of 240 acres divided into three fields—a naturally good soil, susceptible of high improvement, with abudant resources of manure in peat earth and oyster shells. His object is to "*improve his farm, and make the most money in the shortest time.*" We propose that he should substitute *ultimately* for the "*shortest time,*" as more likely to lead to improvement. We advise our correspondent to make a jaunt of observation and of inquiry to the Patuxent, to Fredericks, to the upper part of Delaware, and to Pennsylvania—to Mr. Patterson in his own state, and to the Messrs. Reybolds, in Delaware, and to learn how the best farmers manage matters in those reputed good farming districts. We can only venture to make a suggestion, which is, that our correspondent confine his attention to the improvement of *one* of his fields only, availing himself of all his resources of fertility—till he has brought it into a high state of improvement,—and to stock the other two fields with cattle and sheep. For the course of crops best adapted to his object, we refer him to our remarks on alternating crops, p. 53 of this volume. When one field has been made to attain the desired fertility, attention may then be given to the second and third fields. The latter will be in progress of improvement by means of the farm stock, which will also contribute to enrich the first field. We lay it down as a rule that labor is far more profitable, when applied to *one* field in an improved and highly productive state, than the same labor is when imperfectly applied to *two* fields in an impoverished and unproductive state.

Our correspondent who makes the above inquiries, has appended to his letter the following note:

"Mr. J. Hathaway is certainly mistaken relative to brining wheat before seeded. I bought some this spring of very ordinary quality, soaked it in strong brine one night and part of the next morning, and limed it. It came up soon, and now looks tolerably well."

A PLOUGHING EXHIBITION AND SALE OF CATTLE

Was to take place the 1st of the present month, at Hoboken, under the direction of the American Institute. ☞ The notice of this exhibition came too late for our July number; and it is now too late for us to speak of it in terms which its importance would justify.

MARL.

The specimen of earth sent us by Mr. Fullerton, of Orange; as also the specimen sent us by a gentleman whose letter we have mislaid, and whose name and residence have escaped our recollection, are both marl, but the per cent of carbonate of lime which they contain, we have not been able to ascertain.

ON THE TREATMENT OF COWS BEFORE CALVING.

"A subscriber," who dates at Hoosick, asks whether cows, showing a flush of milk, before calving, should be milked or not?

When the udder is greatly distended, and indications of inflammation appear, cows should be repeatedly milked, particularly young ones, and the udders should be anointed with some cooling ointment, or olive oil, or unsalted butter. A neglect to do this often causes serious inflammation and injury. In old cows unaccustomed to this precautionary measure, evil is less to be apprehended. When tumours appear on the udder, a salve, consisting of one ounce of Castile soap, dissolved in one pint and a half of new milk, over a moderate fire, constantly stirring it till it be thoroughly incorporated, is a good application. An ointment prepared from the juice of the leaves of the stinkweed (*Datura stramonium*) mixed with hog's lard, is also recommended. When the inflammation, however, becomes violent, resort should be had to internal remedies. Where no indications of inflammation, or of tumours, appear, the udder may be left undisturbed.

ERRATA.—The reader is desired to correct two errors in the communication of "P." page 82. In the 10th line, for "substance and for the food of plants," read "substances *used* for the food of plants." In the 14th line, last paragraph, 2d column, dele, or strike out, "own" at the termination of the line.

CORRESPONDENCE.

The Salutary Influence of Agricultural Journals.

Whiting, June 25th, 1838.

HON. J. BUEL—Dear Sir—Having been a farmer all my days, I now, in the sear leaf of life, just begin to appreciate the advantages which the rising generation have over those who, like myself, have farmed it from *tradition.* It is a source of much gratification to me to see farming begin to take a stand, among the varied and multifarious occupations of this busy world, as a *scientific and honorable* employment.

Much of this change—and I hardly know whether it would be saying too much to say, is wholly owing to the untiring and indefatigable labors of a few agricultural papers in the country, among which the common voice of community sets yours down as the *standard work* at the present day. Without feeling the least disposition to derogate from the praise-worthy exertions of the New-England Farmer, a pioneer work—the Genesee Farmer, and others of more recent introduction, now in the full vigor of manhood, all have a strong claim on the gratitude, not only of the farmer, but the nation. I am much gratified to see the increased interest among farmers of patronizing agricultural papers, and frequently when the interesting subject of improving our farming occurs, in conversation among my friends, inquire—do you take the Cultivator? And being answered in the negative, say to them, just hand me a dollar now, and I will send it to Albany, with your address and that of your post-office, and at the end of the year, if you are sick of your bargain, I will take you papers and pay you back your money, noting to them at the same time, that it is more than probable that it will cost them a dollar or two more before the end of the year—that my son and many others had become so interested with the work, that before the end of the first year they had sent and purchased the back volumes. Much good may, in this way, be done to our farmers, to say nothing of the additional patronage it will give the publisher, and thereby enable him to improve the value of his publication.

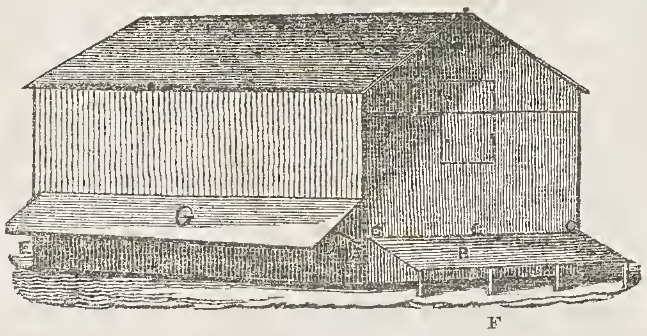
Deacon T. had taken your paper from the commencement, and feeling an interest for his neighbors, got some half a dozen to subscribe for the 3d vol.; at the end of the year he called on them to see if they would continue their subscriptions: one young man hardly knew whether he could, as it would now cost a *dollar.* Well says the deacon, "now look back and see if you cannot think of some improvement you have made from the information you got from the paper the last year, to the value of a *dollar*:" he reflected a minute or two, and replied —"I did save two lambs last spring from some hint in the Cultivator, which are now worth more than two dollars." He continued his paper. Some may be disposed to smile at the simplicity of our young farmer—let them smile if they please, but profit by it at the same time: it was a *genuine practical* observation. "I have saved enough on every acre of corn I have raised for years to *pay all the cost* of the paper, from introducing one implement, the description of which I found in the Cultivator,"* said a venerable,† practical minded friend of mine to me, as I took up his paper and was giving it a hurried glance.

"Any farmer, who will read any single number of the Cultivator attentively, may, by a judicious application of the information he may get, *save* or *make,* more than the whole vol. will cost him," said T. F. B. Esq. the other day, when talking of the importance of farmers taking agricultural papers: he is one of our most thorough practical farmers. I shall take much satisfaction in furthering the circulation of your paper. Yours respectfully. J. A. WALKER.

Portable Barn and Sheds.

MR. BUEL—Sir—The following cut is intended to represent a *Portable Barn* and *Sheds,* which I have lately caused to be erected.

[Fig. No. 39.]



The improvement consists partly in the cheapness of its structure and different uses to which it may be applied.

It can with little hindrance be moved from one field to another; the sills answer every purpose for runners; the end sills and sleepers are framed into the posts, as at A, three feet above the shoe or side sills, which makes a retreat or shed for sheep under the barn. The roofs G, on each side of the barn, are fastened to the posts by tenons, and supported with braces, as at D. The roofs at each end, B, are made fast at the end sills by three hinges C C C. When no use is made of the barn or sheds, or when it is to be filled with hay, the studs, F, are removed, the roof drops similar to the leaf of a table: and when it is desired to prevent winds and storms driving under the barn, the end which stands to the windward may be closed. The draft is fastened at the end of the sill E.

The extra expense of a portable barn, over and above stack yards, will in three years be remunerated in the extra value and saving of hay and labor.

It may be profitably used to improve the barren parts of pasture land as a summer house for sheep.

Yours, S. W. JEWETT.
Weybridge, Vt. June, 1838.

Millers' Tolls.

Rahway, N. J. June 18, 1838.

MR. J. BUEL—Dear Sir—Since your correspondent from Oswego has inquired what toll millers, by law, have a right to take for grinding grain? I have seen by the May number of the Genesee Farmer, and June number of the Cultivator, that Mr. David Walton, of Burlington county, N. Jersey, and Mr. John Westly Luff, of Spring Mills, Delaware, in justification of the millers' extortionate tolls, understand the science of taking toll better than weighing air, or at all events I would not be very well satisfied with their deducting 12 pounds out of every 60 of my wheat for fixed air. Mr. J. W. Luff presumes to make it appear that 60 pounds of wheat contain more than one bushel of loose air, which he cannot prove by practical philosophy. He may make it appear that one bushel of air may, by artificial power, be condensed into a very small compass, but it will not weigh any heavier than when it filled the bushel measure. And I further contend that if he gets more loose air in any species of grain than its circumference will contain, he will be obliged to employ some artificial power to aid nature in her wonderful and mysterious works of its germination. According to the Rev. David Blair's philosophy, under the head of pneumatics, in his experiments in weighing air, he found that it weighed 324 grains for every 1,000 cubic inches; and that it was 900 times lighter than water. Now before Mr. J. W. Luff can prove to my satisfaction that there is 12 pounds, or even 12 ounces, of fixed air in 60 pounds of wheat, he must first prove that the Rev. D. Blair knows nothing about philosophy, or at all events of that part of it under the head of pneumatics. If these gentlemen will take the trouble to make the calculation, they will ascertain that there is 2,150 42-100 cubic inches in a bushel; therefore, if 1,000 cubic inches of air weighs 324 grains, 2,150 42-100, or one bushel, will weigh one ounce and nine penny weights, but no more. I am under the apprehension that the millers in this part of the country have been studying and practising this new science of taking toll. Yours most respectfully,

WILLIAM A. STONE.

Schenectady, 28th June, 1838.

DEAR SIR—Jesse Degraff, Esq. a scientific farmer, on the north side the Mohawk river, just called me to inquire whether I had answered the criticism of Mr. Burnham, (in the Cultivator of this month,) on my observations on early sown grain, as he considered us at issue on the theory of plants exhausting moisture from the ground, and should look for my reply.

I acknowledged to him my want of care in the language used, shewing why early sown grain is favored in times of drought, above that sown late. I explained to him that it must be within the observation of every vigilant farmer, that early sown plants suffered less from the evil of early May and June droughts than those of late sowing. The roots become larger, extend deeper in the soil, whence they obtain more nutriment—through that and the shade of the increased growth of the plants, were protected from the rays of the sun, while those of late sowing became stunted and unproductive. That I had found clover seeds sown on naked ground, failed, because the sun dried the roots when small, and they perished: while those sown with grain were saved by the protection of the grain from the sun in dry weather, and succeeded. He was fully satisfied with these observation, as *he* had made similar remarks, and that they did not contradict the theory of Mr. Burnham, but that an explanation would be expected from me. Will this suffice?

In my communication en the liability of oats to lodge when sown on *strong* ground, and prevented by mowing, your printer said *stony* ground, which made nonsense.

Most respectfully,
DAVID TOMLINSON.

The Grain Worm.

St. Armand, L. C. June 26, 1833.

J. BUEL—Sir—The grain worm having done considerable injury to the wheat crop in this vicinity, for several years past, my attention has been called to the subject, and I think I have found a remedy. My way is as follows, viz: when the heads or ears of wheat begin to show themselves I sow about two bushels of slaked lime or good house ashes on an acre of grain, when it is wet with dew, I repeat the operation once in eight days, until the grain begins to harden and is out of danger. The philosophy of it is simple; the lime or ashes render the plant unpleasant to the fly, so that it will not alight upon the grain to deposite its young. My remedy is *prevention,* which is better than *cure.*

JOHN GERRISH.

REMARK.—We have tried a *single* application of lime, without any sensible benefit. What *repeated* applications would do, we are unable to say; but we doubt the benefit of any topical application, except it contains something offensive, in its odor, to the fly.

We must have Knowledge.

That our farmers may carry into their occupation a "zeal according to knowledge," they *must* be better informed on subjects connected with agriculture.

It is not sufficient, in this country, that a few scientific men direct their attention to it. They, indeed, may, and should lead the way. But they cannot effect so much at once, as in other countries where the many are more under the control of the few.

Here it must be a gradual business. The pioneers of improvement can instruct and influence by precept and example those with whom they come in contact, and thus in time the whole community may be reached, "as the small pebble stirs the peaceful lake." And when this is once done, our intelligent population will turn it to much better account than if they had adopted improvements, they knew not wherefore.

The farmer who avails himself of all the knowledge within his reach, can generally turn it to good account. Every improvement in his business, made in any part of the country, is at once before him for his inspection and adoption. Each hint of the most gifted minds is made to subserve his interest; each new implement to minister to his ease or advancement. New varieties of stock are brought to view, for his selection—new plants solicit his culture. But above all, this knowledge gives him the power of discrimination—qualifies him to select judiciously—and prevents him from being imposed on by pretended improvements.

Plodding ignorance may indeed amass wealth but it is not so common as with the well-informed. And when this *is* the case, it is generally done by a "mill horse" round of toil and vexation, without knowing or caring for any thing beyond the narrow circle in which they move. The present is emphatically an era of improvement; but to the ignorant man all the advantage to be derived from this improvement is lost. Improved modes of culture may render land doubly productive; labor saving machinery lighten the fatigues of labor; change of circumstances unfold new sources of profit; *all* be delineated with fidelity, and spread before the public by the winged messengers of the press; but to him it is a sealed book. He has imbibed a prejudice against "book farming," and nothing short of a miracle will turn aside his steps from the beaten path of his fathers; nothing make him believe that those "gentlemen farmers," who sometimes hold a pen as well as a plough, can instruct *him* who has *worked* at farming all his lifetime.

---

* The Cultivator. † Late Hon. Henry Olin.

Nor are the moral and religious tendencies of agricultural pursuits, in connexion with a good degree of knowledge, to be overlooked. In no branch of science, in no employment of art, are there more numerous or interesting circumstances to call forth the sympathies of the soul, to purify and exalt the best feelings of the heart, to direct attention to the objects of nature, and through them to nature's God, than are to be found in agriculture. To him, who in every opening flower, and ripened fruit, in every sighing breeze and singing bird, and purling rill, can behold and recognize a bountiful Father, sources of enjoyment are continually multiplying.

He who can behold the fertile earth in spring beautifyed with flowers, and carpeted with springing grass; the lavish abundance of autumn, its delicious fruits and golden grain, and feel his breast expanded by no joyful emotions, his heart quickened by no sentiments of gratitude to the great Author of all these blessings, is surely neither to be envied nor admired. If "the undevout astronomer is mad," the undevout agriculturist is doubly so. S.

Dublin, (N. H.) June, 1838.

To increase the Wheat Crop.

It is not the writer's intention to dictate, nor can he claim to have imitated the Emperor of China in even annually giving demonstrations of his veneration for the plough, by entering the field to follow and hold with his own hand that honored and useful implement of agriculture; still he considers his observations for ten years past over the wheat growing district of Jefferson county worthy a passing notice. Winter wheat may be considered the staple grain crop of the middle, western, part of the eastern and southern states; in northern latitudes, it has to encounter many enemies. No doubt the one most formidable, is the prevailing winter or spring night frosts, and thawey drying days, the ground being left in a flat state or in lands too wide and without sufficient cross furrows to carry off the surplus moisture; large fields are thus drawn by the frost and wilted by the sun. It has been observed, and I assert the rule to hold good, that wheat ploughed in from 20th Aug. to 10th Sept. in narrow lands, shallow furrows and well cross drained, to a great extent escapes the injury of the heaving frosts of winter and spring; the ground preserving a more uniform moisture sufficient to facilitate a proper growth, and in clay soils does not become baked. Good crops is the consequence. I would recommend ploughing in wheat in lands of six furrows wide, (about six feet,) leaving the furrows between the lands open, making cross furrows in all low parts of the field, that it may be properly drained. Some object, as it leaves the ground rough for gathering the wheat, and subsequently the grass, if it is seeded down; but I would not seed down upon winter wheat when the frost so materially affects it. Seed with spring crops.*

Many farmers do all the *hard work* of raising a good crop, the operation of putting in the seed is done slovenly, as all work is done in a hurry and without care. Some skill is requisite to plough in wheat in the manner here suggested. The furrows should be straight, so that the last one will be of even width and have no balk. It is much to be regretted, that many, priding themselves upon their spacious acres and *chance* fine crops, do not possess the knowledge of ploughing well, or at least omit to practice it with skill. How beautiful to the observing traveller appears a field of wheat newly sowed, upon ground in all respects properly prepared and ploughed in, as here suggested; how agreeable to the farmer to hear, borne upon the wind, the traveller's remark, "This man is a farmer, his work is done neat." Such an one is "a farmer." He needs not sow a second time but gathers a crop, not in patches but *a full one,* 25 to 40 bushels per acre. This *notion* some have of leaving wheat land flat to make better harvesting of that and subsequent grass crops, evidently has reduced the wheat crop millions of bushels annually.

TO BEAUTIFY THE COUNTRY.

Since the settlement of the American continent the primitive forests have been removed from vast portions of its fertile and diversified surface. By a few, primitive trees have by chance or accident been suffered to remain near intended dwellings and by the way side; many have planted their tree in early youth, and in age reclined beneath its grateful shade. Such are now more dear to descendants, recollecting their enjoyments in this respect were provided for by time honored ancesters.

The "new beginner" in a wilderness country seeks to remove the impediments to cultivation. In most cases not a tree is suffered to grace the yard of his isolated log cabin; his fields are rendered alike barren as to natural ornament. Now it is quite as easy in clearing new lands to leave a few trees of moderate size and in suitable places upon the road side, about building grounds, and clusters where division fences are intended. Thus we may have beauty without cost, and that too at least twenty years in advance of planted trees. It may be proper here to remark, that such trees being *natives,* will uniformly *live* if left uninjured, which is less certain with *planted* trees; in this way you may have a variety, and every tree standing upon soil the best adapted to its growth. But reader, if you have a farm without trees to *leave,* by all means *plant* and raise them. Natives of the farm look well; scarce any are better.

In suggesting this mode of raising good crops of wheat and of beautifying the country, I am aware neither is new with many tasty farmers; but the fault or neglect, if it may be so termed, prevails to a great extent in both respects.

Let him who prepares his ground well, sow clean seed in season, *and plough it in* as by the writer suggested; or him who is by these suggestions incited to save from the devouring axe a few trees for his shade, place the good or evil consequences to the account of

OLIVER CHILD.

Carthage, N. Y. July 6, 1838.

P. S. As the Cultivator is not read by but few of the active farmers, comparatively speaking, I have to request that the good suggestions every number is made to contain, may be treated as Indian history, handed from one to another in conversation, and from father to son transmitted to posterity. Country papers dry of news, would greatly improve the value of their sheets, by more frequently copying essays upon agriculture.

Remarkable abstinence in a Calf.

Washington, D. C. July 13, 1838.

Jesse Buel, Esq.—Sir—A fact, singular to me, came to my knowledge a day or two since, which I cannot forbear communicating for the benefit of such of your readers as may be curious on such a subject.

A gentleman sent his cow, among his other cattle, into my brother's pasture, a few miles from this city, to feed. After a few days, thinking the cow near the season of parturition, he had her driven up into his barnyard. She remained in the yard with other cattle nearly ten days, when, no signs of "labor" appearing, the owner began to wonder at the cause. It finally struck him that the cow must have calved while in the pasture. He therefore, after the laps of *eleven* days, sent the cow back to the pasture, and his wonder ceased on perceiving the cow hastening to a little copse, where, much to the gentleman's surprise, he found the calf *alive,* but in a most miserable emaciated state. The mother revived her offspring, with the help of the owner, after a little time, and strange to say, the little creature is doing apparently as well, as if he had been ushered into the world under different circumstances and attended with ordinary care.

The cow was fat, and we may hence infer that the calf, when first born, was in good condition. It is probable it never suckled until after the lapse of the eleven days.

I have no time for comment.

In haste, very respectfully, your ob't servt.

THO. ALLEN.

The Strawberry.

New-Haven, Conn. July 4, 1838.

Hon. J. Buel—Dear Sir—I am glad to see that you propose giving, in your next number, some directions for the culture of the strawberry. Before preparing your article, I take the liberty to suggest for your inquiry, whether it is *necessary* to intermix the two sexes.* If it is not, great trouble, expense and eventual disappointment will be spared to the cultivator, by planting females only. I have cultivated what is here called the Chili strawberry, which has no stamens in its blossoms, for nineteen years, wholly by itself, without any mixture of males; and have never failed to have fine fruit. For five years, I have cultivated, also unmixed, the Methven and a seedling strawberry, both with female blossoms only, with entire success. It is true, I have had, at the same time, in my garden, a few plants of another strawberry, whose flower is of both sexes, but at a distance from the rest, and so few in proportion to the others, (say one square rod in eighty,) that I can hardly suppose them to have had any fructifying influence.

From these facts, I have been led to doubt the necessity of mingling the different sexes. That would doubtless be indispensable to the perfection of the *seed,* but please consider whether it is to the perfection of the *fruit.*

We have analagous examples of perfect *fruit* from female plants alone, in the fig, and if I am not mistaken, in the mulberry, at least the black mulberry.

I make these suggestions with no small diffidence; for I know the universal opinion of nurserymen and gardeners is against me. But if I am right, the cultivation of strawberries may be greatly simplified, and success will be certain to the careless as well as the vigilant—an important consideration, especially to the farmer who has other cares enough upon his hands.

Yours, &c. NOYES DARLING.

P. S. My practice has been invariably to plant out my strawberries in the *spring.* I lose none by dry weather; the perennial weeds and grasses are easily extirpated by the hoe the summer following; and the next year brings the beds into full bearing.

National Agricultural Association.

Lake C. H. Ia. June 19, 1838.

J. Buel, Esq.—Dear Sir—I cannot but feel a proper degree of pride to perceive what universal approbation, my proposition for an "American Society of Agriculture" meets with. Not pride for myself, because I happened to be the first to make the proposition; but pride for my country, to perceive that there is so much of the true spirit yet alive in the land. I have received several letters and papers containing notices of the proposition, which indicate to my mind, that "something can be done." Organization is all that is lacking. That "must be done," and then the last affirmative in the proposition is sure to follow. For if all the friends to agricultural improvement are once united, "something WILL be done, to elevate the character and standing of the cultivators of the American soil." There is a charm in the very name of "The American Society of Agriculture," which is sufficient to enlist thousands. Something so ennobling in the thought of being known to be one of the members of such a union of all the most eminent agriculturists in the whole country, moved and actuated by one impulse, and mutually interchanging their views, experiments, improvements, and newly acquired information.

What an immense influence would this have upon the whole country. Look at the influence upon mechanics of the American Institute. Greater still would be the influence of such a union of agriculturists. Look at the influence of agricultural schools and pattern farms. This would be one great agricultural school upon a thousand pattern farms, the annual exhibitions from which would do wonders towards inciting others to go and do likewise.

We cannot look to legislative action, for that encouragement and protection which the agricultural interest is entitled to, until the tone of public feeling is further awakened to the importance of the subject, by the immediate action of the cultivators themselves, and until the subject can be made popular, and then it will lack no assistance.

Can any plan be devised that will have a greater tendency to create that popularity than the formation of the "American Society of Agriculture?" If so, let it be done. I enrol myself one of its friends and supporters. But the time is fully come that "something can be done," and I shall lay my grey hairs sorrowing in the grave, if the whole country does not respond, "something must, something SHALL be done," and done quickly, to promote the great, and good object in view.

Yours, &c. SOLON ROBINSON.

On Curing Clover Hay in Cock—Heaves in Horses.

Queens County, July 4, 1838.

Sir—There is one objection to your plan for curing clover hay in grass cocks, which has always struck me as insurmountable, viz: *that it must be so long out o' doors.* In the Cultivator for this month you say, "leave them (i. e. the grass cocks,) undisturbed at least 48 hours." If we could be certain of good weather, this would do well; but suppose that before the 48 hours are expired, we get a heavy shower of rain, what then? Why the grass after a pretty good drenching, is to be thoroughly cooked in the sun, during which process, its fragrance will most assuredly take wing, to return no more; and next a considerable portion of the leaves will crumble off, before it reaches the mow. My plan has long been to rake and cock in the afternoon what was cut early enough in the same day, to have taken a nice wilt—next morning as soon as the dew is gone, these cocks are turned over, and if necessary opened a little. In two hours they will do to cart. Hay made in this manner, saves perfectly, and is of the very best quality and appearance. If there happens to be a brisk drying wind through the night, the cocks will sometimes do well to cart without opening. I may be mistaken, but I cannot help believing that this process is, on the whole, preferable to the one which you recommend. I know it is not very grateful to have our cherished and proclaimed opinions, successfully assailed; but I have mistaken your character, if fair and manly discussion, is not invited by the Cultivator. We will change our subject. Do you know of any effectual remedy for heaves in horses? If not, perhaps you may consider what follows worth noticing. I have a valuable horse—one of a pair—which threatened more than a year ago, to become utterly useless in consequence of this complaint. At the expiration of the last grass season, I was induced to try top-stalks instead of hay, and the result has been that the animal is entirely relieved, nor have I the least expectation, that the disease will recur to any extent, so long as this diet is adhered to. Permit me to add, that I have for years, been in the practice of giving my horses each an ounce of fine salt every other day: and that I have good reason for believing that their health is greatly promoted by it. In reference to stalk-fodder for horses, I should like to inquire, through your paper, of southern gentlemen, whether in that part of their country where hay is not made, they ever have heaves amongst their horses. If they do not, I shall consider my experiment conclusive.

---

* The winter killing of wheat is to be principally ascribed to the expansive power of frost upon a wet soil; and the evil is annually increasing, by the diminution of the vegetable matter in new settled districts, by hard cropping. This diminution causes the soil, especially where clay predominates, to become more compact, and consequently more liable to be affected by frost. The remedy suggested is a good one; and yet if furrow draining was introduced, the ridges might be laid 18 or 20 feet broad, and thus the objection to six feet or narrow ridges obviated. The land would thus be always comparatively dry, and in condition to work early, and the crops would be certain, and upon an average one-third more, on a field of stiff clay, than they are now. An increased product of ten bushels an acre, would remunerate for the outlay in two or three years. We *know* that under draining almost effects miracles.—*Conductor.*

*We possess no evidence that this is necessary except with one variety of the hautboy—but we think the rule will apply to some other varieties of this fruit.

Very respectfully yours, A SUBSCRIBER.

JESSE BUEL, Esq.

P. S. Our crops of hay will be rather light. Oats were checked in mid career, by a sharp little drought which we had last month; and from present appearances will be nothing to brag of. Wheat *has* looked prodigiously fine, but we are now a little apprehensive of rust. Corn, what the worms have left, is very promising. In sandy soils, these worms made great havoc, while in loam, little harm was done. The difference here named, is obvious; even in the same field, some of our corn has been planted over three or four times; the last time we used the Dutton, hoping it may mature notwithstanding the advanced state of the season.

REMARKS—The objection of our correspondent is more plausible than substantial. The object of curing clover in grass cocks, is to preserve its intrinsic good properties; and although the exterior of the cocks may become blanched by a long exposure, the interior will not suffer deterioration, if they are properly constructed, by a week's exposure, but will be bright and fine. And it makes but little difference on the score of economy whether the hay is housed the second or fifth day after cutting.

We have this year varied our practice somewhat, and we think to our advantage. The grass cut in the forenoon, has been turned in swath directly after dinner, and put into grass cocks the same day. If rain has threatened, the cocks have been opened the second day, and the hay finished; but we prefer to leave them to the third day, when a slight opening, to evaporate the external moisture, suffices. The grass mown in the afternoon is turned the same day in swath, or if not wilted enough, in the forenoon of the second day, and in the afternoon put into cocks. We deem it important, 1st, that clover should stand in cocks some time in order to equalize the moisture—to sweat—that is, that the moisture contained in the thick stems may have time to disseminate itself upon the surface, and into the thin leaves and blossoms. If a slight fermentation takes place in the cocks, so much the better; as the hay, in that case is not likely to undergo a second fermentation in the barn. Secondly, that the curing process should be carried on as much as possible without the aid of the direct rays of the sun, which certainly impair its nutritive properties. Expose a lock of clover two days to the direct influence of the sun's rays, and it becomes blanched and valueless, and cattle will reject it.—*Cond. Cult.*

Draining—Prairie Barrens of Ohio.

Chillicothe, Ohio, June 12, 1838.

J. BUEL, Esquire—I am much pleased that you have so thoroughly taken hold of the subject of *draining* lands. It is a subject which has been but little thought of in this section of the union, though one in which we are so deeply interested; and I am confident that some of our lands, heretofore but little thought of, will by this operation be found among the best in the country. We have done but little in top draining; and under draining, to my knowledge, has not been introduced. On many of our lands in the Sciota valley, I presume it would answer a good purpose; but the scarcity of stone seems to be a difficulty in the way of its introduction, pottery would be too expensive, and wood, though sometimes used in Europe, I fear would be of too short continuance, as it rots sooner than in Europe or in the United States east of the Allegany Mountains. We must, therefore, I presume, be principally confined to top ditches. By the application of this, I am confident, that some of our lands, heretofore but lowly valued, will be found in *reality*, to be among our most valuable. The greatest quantity of our land in this section of the state, which needs the drain, is high and very level; a great portion of it bordering on the heads of the streams, and in many places, with the naked eye, you could scarcely decide, which way the water runs. The channels are in many places to a considerable distance closed. In all these places there is sufficient declivity, as soon as a channel is opened, to carry off the water. I have had a little experience of the effect of *slight* top draining upon a stock farm, which I have, called Wahoo Glade, about 24 miles west of Columbus, in what is called in this country the "Barrens." It consists of prairie and very open barrens. The prairie is a deep black soil, founded upon a hard pan or stratum of dark yellow clay and limestone gravel; and the barrens a dark yellow clay soil. When I commenced the farm, my principal object being grass or grazing, I went to work to put the prairies into tame grass, without breaking the sod. The large glades were then considered so wet that corn or grain could never be raised upon them. This I find a great mistake, and one which has cost me money, and the sacrifice of much time in the improvement of my farm. Experience has taught me, that those glades by *proper draining* are capable of making some of the best and most durable tillage lands in the country; and that the plough is the best instrument for subduing the prairies and barrens, and for putting them into tame grass. I manage it in this way; I run a *large* ditch through the glade, near the natural direction which the water takes in passing off. Then, before breaking the sod, I turn about three furrows down each swell to the main ditch, and throw them out about 18 inches deep, so as to make a flaring passage or ditch to the main ditch. I then commence breaking up the sod, extending my lands across those swale passages, and making them only from one to two rods wide, and cut about nine inches deep. This throws the face of the land into ridges, and gives drains to conduct the water into the swale passages, and thence into the big ditch. The next year observe the same order of ploughing, and keeping open the swale passages, and so on until laid down to grass. After it is laid down to grass, the swale passages sward over, and there is no loss of the use of any of the land. After thus preparing, and throwing the surface of the land into the aforesaid shape, I can raise upon it a good crop of corn, wheat, &c. After laying it down, it swards over thickly, and the grass seems to be of a more substantial quality than the tame grass produced upon the land before draining and ploughing.

I have suggested to several gentlemen of mechanical genius the great utility of a machine for digging ditches,* but have never seen any invention.

Very respectfully, &c.
NATH. SAWYIER.

Singular Effects of Gypsum.

J. BUEL, Esq.—Sir—No doubt your are pleased to hear any remarks that will benefit the agricultural community. I therefore remark, that on Saturday the 16th of this month, we commenced applying gypsum to our corn; we commenced late in the afternoon, and only plastered about one-third of the field, which contains about 4½ acres. The ground was dry when we applied the gypsum. On Sunday, we had a very heavy shower. On Monday we plastered the remainder of the field. There was a drain that led from the highway into the field, which conducted the water into it. A few perches of the land were in puddles; but when the last plaster was applied, the water had subsided, but yet the ground was soft where the water had stood; in those spots we soon after discovered that the corn was evidently perished! and all over that part of the field last plastered turned yellow, ceased to grow, and now looks miserable. That part first plastered looks black, thrifty, and is twice the length of the latter! It is to me a full evidence, that gypsum applied to wet, or moist land is a damage in lieu of a benefit; and never ought to be applied to corn after a rain, until the ground gets dry and warm. It is proper to observe, that the two parts of the field are about as equal as to moistness as you will find generally on high, hilly land; not any of it wet, but dry land. The odd appearance of the corn commencing at a row, and continuing through the field, is so conspicuous that people travelling by, will stop, wonder and inquire. No doubt it is generally understood by farmers, at least by those who have read the Cultivator, that gypsum is a damage applied to wet, or moist land.† The circumstance of the application of it, evidently proves, that it never ought to be applied, even on the dryest land, even in time of a drought, when there has been a dew during the night, until the grass, if applied to mowing or pasture lands, or grain, until the dew be wholly evaporated from the earth. I should say not till afternoon. I am convinced the usual practice of applying it promiscuously, is the cause of farmers saying that it will not have the same effect every year. It is common to commence early in the morning, before the wind rises, and also to escape the heat of the sun, having no consideration to moist effect. Henceforth I shall never apply it only when the ground is dry and warm. I am, sir, yours respectfully,

JN. SEELYE.

Sherman, Connecticut, June 25, 1838.

The Times.

AGRICULTURAL BRETHREN—For some time past, we have seen much written, and heard much said, about scarcity of money and hard times. Great complaints have been made by merchants, manufacturers and mechanics, in every town and state, in this extensive country; and no doubt there has been much difficulty and cause for alarm. The currency has been, and is still, much deranged. In consequence of this, our money concerns have been brought into such a state, that confidence between man and man has been, in a measure, lost. On this account, a vast amount of money has been kept from circulation. On the eve of our late prosperity, many in their eagerness to become rich, took, as it were, a leap in the dark. They were not apprehensive of a change of times, and undertook many things without counting the cost. In this way, thousands have been ensnared; and from their toils have not been able to extricate themselves. Though I deprecate this change, and pray not for a recurrence, yet, in many respects, I think it will eventually be for the good of the people. The change of times has brought folks to see on what they must depend for subsistence. I hope it will have a tendency to check wild speculation and headlong extravagance. These had become very prominent, and needed a powerful restraint. The times have tried men, as a severe drought tries our wells. When this happens, wells, without good bottoms, fail. So fail men in a great money pressure. These things are bad; but may they not be productive of much good in after life, and to future generations? Will it not make them more cautious and provident? I very much rejoice, brethren, that I am able to say, that no class of people have withstood the times so well as the farmers. "The rain descended, and the floods came, and the winds blew, and beat upon their house; and it fell not: for it was founded upon a rock." Yes, we have irrefragible evidence, that agriculture is the groundwork of living. In the many complaints made by the people, we cannot altogether exclude the farmers. We occasionally hear some exclaim, "O tempora!" It is true, they have been somewhat affected by the currency, and the seasons of late have been rather unpropitious; yet, as a whole, the tillers of the soil have had great occasion for thanksgiving. Providence has frowned, but she has also greatly smiled. Almost every thing that the husbandman has furnished for the market has commanded an enormous price. While labor and articles of merchandise have been falling, articles of living have been rising. I very well know, that some of our brethren have met with embarrassments, but I believe it was not so much owing to the *times*, as *other* causes. But on thorough investigation, I find, that this trouble is brought about very much by conforming to a *cruel* and *tyrannical fashion*. Yes, it is a stubborn fact. Extravagant fashions are introduced, and folks, whether they be *rich* or *poor*, must follow them. Consulting ability is out of the question. As I was following my plough, the other day, my meditations were disturbed by the cracking of a whip, and rattle of a chaise. Raising my eyes, I saw a young man passing in the road, in the greatest possible style. Who can that be, said I? Has *Crockett* come among us? Moving in such uncommon style, I had the curiosity to find him out. And, on inquiry, found him to be a man destitute of property and the materials that constitute a good character. By following the extravagant fashions of the day, he became embarrassed; and embarrassment led on to bad habits. He expended much to decorate the *body*, but *nothing* to improve the mind and heart. Here he was unwise. On this rock thousands and tens of thousands split. To this thing, brother farmers, I wish to direct your attention. Is it not a lamentable fact, that we are too much under the dominion of this *hydra, fashion*? Do not these wild extremes *injure* and even *shipwreck* a vast many? We, as a body, can boast of a *competence*, but not of *affluence*. It is not in our power to do as some do, and, if it were, it would not be proper to do it. Persons of real merit appear much the best in a plain, neat and simple dress. "Loveliness needs not the foreign aid of ornament; but is, when unadorned, adorned the most." Simplicity of living is far preferable to epicurism. A snug, decent style of moving is much more commendable than extravagance. Would it not, brethren, be well for us to retrench our expenses, in some particulars, and do more for the improvement of the mind and heart? While we are providing for ourselves and households, and improving our farms, let us not forget the cultivation of the mind. Let us not forget the minds of our children. Laboring people may be reading people. Laboring people may be intelligent people. In this land of free schools and exalted privileges, let no one say (of common intellect) that he cannot get a good education. For every thing there is a time and season. There is a time for manual labor; a time to eat and a time to sleep; so there is a time to improve the mind. Farmers may read much every day, and digest it when about their work. There can be no reasonable excuse offered, why they should not progress *daily* in useful knowledge. I contend that a man may accumulate property as fast, to read some, every day, as to be all the time plodding. Likewise, that a student may labor some with his hands, without detriment to his education. This alternation, experience, (the best of teachers) has proved to have the most salutary effect. It is absolutely necessary, that both body and mind be exercised, in order to be healthy. It is a pleasant consideration, that while the manual laborer is resting his wearied limbs, he may be improving and enriching the mind. That while the student lays aside his books, to relieve the mind, he may, by manual labor, be invigorating the body. Thus, has a kind Providence ordered things for our happiness and interest. And it is astonishing, that people do not more regard her dictates. I have written some, respecting the tyranny of *fashion*. I am very sensible, that people do not consider, what *dupes* it makes of them. How it picks their *pockets*, beggars their *families*, sterilizes their *minds*, and makes them perfect *slaves*. I hope the time will soon arrive, when we can say the times are changed, and we are changed with them.

AN AGRICULTURIST.

Westborough, Mass. June 1838.

Under-Draining.

Countsville, S. C. July 8th, 1838.

HON. JESSE BUEL—Dear Sir—I again intrude with my queries. I have a wet lot of land in which, on a line of springs beneath the surface, I have cut a ditch which has not absorbed the water as I anticipated. My intention now is to underdrain it. As stones are not in any abundance about the place, and tile not to be procured, I wish your advice as to whether an underdrain, constructed of boards of good pitch pine, (which I can procure in abundance,) would serve to carry off the water, and render my land arable? These boards will last, perhaps, a century, when excluded from the air. How would it answer to lay two straight logs and cover the top with a board? As I *have never seen an underdrain*, on a farm, I would respectfully solicit your valued opinion on these matters. I shall be mindful of the instructions which you gave to my queries in the July Cultivator. I am truly yours.

---

* A machine of this kind has been patented by a gentleman near Baltimore, and one has been sent by Mr. Ellsworth to the valley of the Wabash for trial.—*Cult.*

† We have not supposed that gypsum is a *damage* to wet ground, but merely that it produced no benefit.—*C. Cult.*

A. SUMNER.

REMARKS.—If the pitch pine boards or plank of South Carolina will last a century under ground, they will constitute an excellent material for underdrains—and we should use them to the exclusion of logs. Let the top of the box be covered crosswise, and not longitudinally, with plank, and take care to sink the drain low enough into the impervious stratum, if practicable, to catch the water coming from above, and to fill the lower portion of the drain with porous materials, that the water coming from the higher ground may settle into it and pass off. If spouts or springs rise in the low ground, these fountains must be reached and conducted off by underdrains; and if the wet lot is large, cross or diagonal drains may become requisite.—*Cond. Cult.*

Beat this, Eastern Farmers.

MR. J. BUEL—Sir—I have noticed in some of the numbers of the Cultivator, what your eastern farmers call brag crops, or raising a great quantity of grain on a small piece of land. I will give you a statement of one or two crops of wheat, &c. that have been raised in this vicinity the last year. A Mr. Arland, who emigrated from N. Y. to this section of the country last season, rented 40 acres of land adjoining the town of Dixon, and the following crop was raised by himself and wife, (by the way he is a German, and the women you know, as well as the men, are cultivators of the soil.)

20 acres of corn, averaging 40 bushels to the acre, which sold for 75 cents per bushel, making	$600 00
15 acres of oats, averaging 35 bushels to the acre, which sold for 62½ cents per bushel, making	323 00
2 acres of spring wheat, which produced 82 bushels of good clean wheat, worth $1.77 per bushel,..............................	143 00
300 bushels potatoes, worth in the fall season of the year about 37½ cents per bushel,	112 00
What was sold from his garden amounted to something like 50 or 60 dollars, say......	60 00
Making in all the sum of	$1,243 00
For the use of this 40 acres he paid $4 per acre,..............................	$160 00
His own labor during the raising and securing the crop, also his wife, is worth..	300 00
Paid hands during harvest, threshing, &c...	90 00
	$550 00

Making a clear profit in six months of the beautiful sum of $693.

Who would not be a farmer on Rock river? The above is no exaggerated story, the facts are known to all who are acquainted with the farm and the farmer who produced the crop.

Now Sir, will you be kind enough to turn the other ear, and I will stuff that with such a crop of wheat as none of the eastern farmers can boast of. A gentleman by the name of Saml. Reed, living in Buffalo Grove, 12 miles N. W. from this place, had a piece of wheat of 14 acres; shortly after harvest he threshed out one acre of this piece, and it produced *fifty bushels* of good clean wheat. I happened there at the time he was threshing. He has since informed me that the whole piece averaged 50 bushels to the acre, making in all 700 bushels. This wheat was sold for $2 per bushel, a great part of it for seed, he being one among the best farmers of our country, and very particular about his seed. Is there a farmer in any of the New-England or Eastern States can raise 700 bushels of wheat from 14 acres? Think of this you that are toiling among the stones and stumps, and pull up stakes, come to Rock river and raise wheat, get rich in ten years, and live on the interest of your money the rest of your life.

A SUCKER RAISED BUT YORKER BORN.

Dixon Ferry, June 25th, 1838.

The Curculio.

Scottsville, Albemarle Vir. 5th July, 1838.

SIR—I like a good idea, come from what source it may. A few days since, a stage coach companion and myself were comparing the relative advantages of our respective regions of country. In speaking especially of the peach and apricot—which with us is barely worth cultivation, being destroyed by the insect, which saps the tree at the foundation, and I presume perforates the fruit and renders it gummy. He informed me that a remedy was in practice in his neighborhood, which very effectually prevented the depredations of this relentless foe to our trees. It is simply paving around the roots of the tree, so as to prevent the insect getting below the surface of the ground. This may be done in a variety of ways: with small stones, using a wooden box to answer as a curbing, extending some 12 inches from the root of the tree: by the application of a well made mortar of lime and sand: or by sawing a hole in the centre of a wide plank, fitting it closely to the tree, then filling the interstices with putty: or, lastly, by what I regard the best plan—mixing tar and sand, to a proper consistence, excavating the earth to the depth of two inches, twelve inches around the tree, then filling up the excavated portion with the cement—this, with a trowel, can be smoothly laid, and accurately adapted to the body of the tree. Whether the theory be correct I know not: there is plausibility in it; it is to some extent new to me, and he informs me unpublished, so far as he knew. If the idea is worthy of notice you can use it; if not let it take the fate it merits. Your most ob't se't.

J. BUEL. G. M. LEWIS.

REMARK.—This preventive, if efficient, can only be adopted on a limtied scale. But we doubt its efficacy. The curculio, which does the mischief, is a winged insect, with locomotive powers. Hogs and poultry, which destroy the insect, are the best preventive. All stone fruits are subject to a like calamity, though in a less degree.—*Cond. Cult.*

Hoyt's Improved Patent Drill Barrow,

Operating upon the principle of keeping the seeds constantly stirred up at the bottom of the seed box, and forcing them out, instead of leaving them to fall out by their own gravity.

Description of the Cuts.

[Fig. No. 40.]

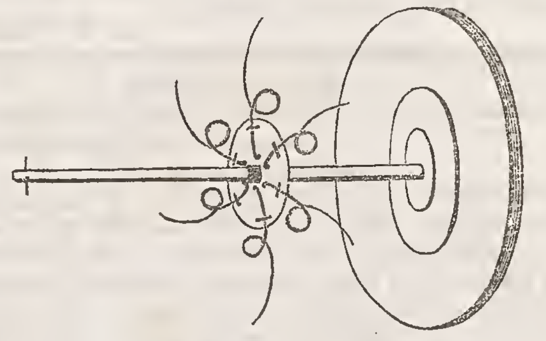


Fig. 40, an iron shaft, ⅜ of an inch in diameter, 7 inches long: on one end a double pulley and six springs or arms, of iron or steel wire, attached.

[Fig. No. 41.]

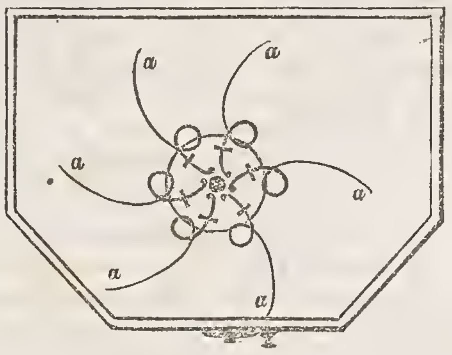

Fig. 41, seed box, of wood, 9 inches long, 7 inches deep, 5 inches wide, represented with one side removed, to shew the situation of the springs or arms inside of the box.

[Fig. No. 42.]

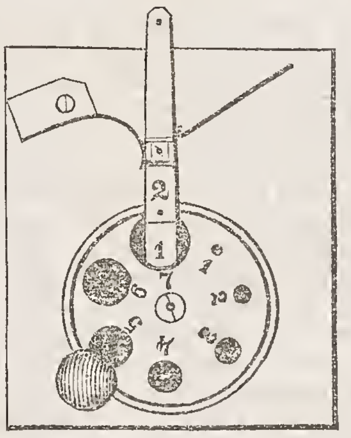

Fig. 42, bottom of seed box of tin, attached to which by a screw in the centre is a brass wheel, 2 inches diameter, 3-16 of an inch in thickness, with holes of different sizes, in the outer edge numbered from 1 to 7: this wheel turns on its centre, and the hole to be used is turned exactly to the centre of a large hole in the bottom of the box, and secured by a thumb screw; the shaft is set in motion by a band from the running wheel of the barrow, and passes the spring arms *a a a a a a* across the hole in the brass wheel, and stirring up the seeds falling into it as it passes with sufficient force to eject any seeds which may not fall out: a valve is placed at the lower side of the brass wheel, which is kept shut by a spring, and prevents any seeds from falling out, except just as the springs are dropping into the hole, when it is opened by the turning of the shaft, lets out the seed, when it instantly closes: the distances between the hills is regulated by the size of the whirrs.

[Fig. No. 43.]

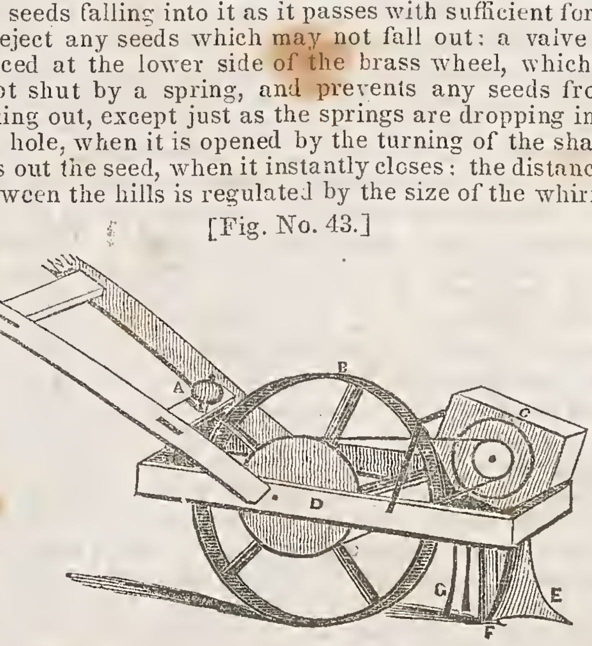

Fig. 43, barrow complete. D, frame; B, cast iron wheel; C, seed box; E, share for clearing away in advance of the plough; F, plough, and the end of the tube through which the seeds are passed to the ground; G, iron rods, to turn the dirt on to the seeds and the wheel passing over it completes the planting; A, a screw to regulate height of handles.

This drill may be used for turnips, carrots, beets, beans, and all like garden and field seeds.

Climate, &c. of South Florida.

NUMBER ONE.

Key West, South Florida, June 12, 1838.

MR. BUEL—SIR—I am desirous of furnishing for your paper, a series of articles upon the character and condition of South Florida; and I send you this my first number for consideration. Should it find sufficient favor in your sight to secure it a place in your columns, the subject will be continued with much pleasure. It is designed to speak of the country as it is—neither to exaggerate its favorable characteristics, nor to omit a sufficient detail of the objections which are justly chargable to this as well as to all other places under heaven.

The fact, that South Florida is the only part of the United States that possesses a tropical climate, is sufficient, it would seem, to give it a peculiar interest in the minds of our intelligent countrymen, both for the advantages which would result to the nation from its settlement, and the satisfaction it would afford to amateurs in agriculture in general, and horticulture in particular; and for the healthful retreat which it holds out to our northern invalids, where they may temporarily withdraw from the severity of their winters, or permanently settle and make for themselves a delightful and even luxurious home.

The little information I possess respecting South Florida, has been gathered during a short residence of only sixteen days at the Cape, where I intend to settle permanently, and a *stay* at Key West for the last two and a half years, where most of the inhabitants of the former place have resided since the commencement of the war. Of all these people I have made diligent inquiries; and upon their united testimony, carefully sifted and balanced, together with my own observations, are based the views and statements now offered to the public.

If it be objected that this information must necessarily be too limited and uncertain to command the reader's confidence, he may be assured that they who have written the most, and been the most liberal and positive in their praises and denunciations of this country, are even less acquainted with it than myself.

It is true, as has often been alleged, that South Florida abounds with inundated lands and swamps, and contains but a small proportion of what is generally termed good soil. Nearly all the interior is an unexplored region of fresh water lakes and wet savannas, whose extent is certainly great, though altogether conjectural. But even in these are wood lands, whose value and extent are also unknown. The lands bordering upon the bay at Cape Florida, (a sheet of water perhaps twenty-five or thirty miles in length, coastwise,) are chiefly dry and fit for immediate settlement. The same may be said of a great portion of the coast to the northward of that place. But to the south, after passing the limits of the bay, the coast becomes low and subject to occasional inundations, in some places by the sea, in gales, and in others, by the fresh water from the interior, throughout nearly its whole extent around Cape Sable as far to the northward as Cape Roman, and from thence there is but little improvement in the coast south of Tampa Bay. This belt of dry land at the cape is not more than from three to perhaps six or eight miles wide; yet here the first settlers of South Florida will undoubtedly make their location.

Having premised thus much, I will now venture the assertion that *that class of people for whom I now principally write, can no where find another place so fully adapted to their wants as Cape Florida and its vicinity;* and I proceed in the sequel to prove this assertion.

The class referred to are inhabitants of the northern states, who prefer their own republican government to all others, and therefore would not willingly leave it, but the state of whose health, impaired by the rigors of their cold and fickle climate, requires their removal to some country where those evils are not felt—who have few motives of pecuniary gain to gratify; no desire to dwell in populous towns in slavery to fashion, folly, and artificial wants; no itching for speculation in lands and paper village lots, or for the sudden amassment of money in any way; but who desire, and have refinement, and taste, and philosophy enough to spend their days in the quiet and virtuous enjoyment of rural life, enclustered in an independent little world of friends and neighbors, where summer reigns perpetual in undying verdure—or again, those of our countrymen who from natural temperament and taste prefer our southern clime; or who, though industrious, intelligent, and valuable members of society, are struggling with the evils of poverty, and harassed with anxiety for the present and future wants of their growing families—who dread the approach of winter for the multiplied expenses which it demands, where the means are already scant, and rack their brains in sleepless nights to devise some change for the better which never comes; and who would joyfully fly to our southern clime, could they but see their way clear to a comfortable subsistence—these compose that numerous class of people of whom I speak, and whose patient attention I now desire to engage.

The climate—particularly at the cape, and adjacent isles, has been sufficiently tested to put to rest all question of its salubrity. That vicinity has been inhabited by a population averaging perhaps about forty in number, for the last forty years; and their united testimony is extravagant in praise of its peculiar healthiness. They assert without exception that there has never been a case of sickness there of any kind; and they frequently compare that place with Key West, giving a decided preference to the former, in which they are never contradicted. Yet Key West is *now* as healthy a place as I have ever known or wish to live in. Therefore, without sanctioning these extravagant assertions, we may safely conclude that the climate at Cape Florida is unusually salubrious. Yet to a person unacquainted with the causes which operate to make it so, it may seem strange that the interminable marshes with which the country is known to abound, do not produce sickness. They undoubtedly would do so, were people to settle in the worst of them, and there spend much of their time at fatiguing labor and exposure. I say the *worst* of them, because many of these swamps, as they are called, and indeed a great portion of the everglade, are merely shoal bodies of pure moving water, covering a bed of white sand—others are low prairies, covered with short stinted grass, sometimes dry, sometimes wet, and sometimes entirely inundated; the soil of which, though I have never examined it, I believe to be a lime marl—and others are doubtless composed of that loamy soil the tendency of which when marshy is always unhealthy. Furthermore, the settlements have been chiefly confined to the coast, over which the easterly winds from the sea are, a great portion of the time, blowing, and driving from them the miasmata that may arise from the wet grounds in the rear. The ridges on the coast are at an elevation of from ten to twenty feet, composed principally of sand resting upon a limestone base, and clothed with extensive pine forests, diversified with intervals of marl prairies. These circumstances are sufficient to explain the cause of the peculiar healthiness of that country.

I am aware that northern invalids often fear the effects of our summer climate. I did so myself before trying it. But they who have any disposition to pulmonary complaints, and indeed most of the inhabitants here, greatly prefer the summer to the winter. There is a purity—a luxury in our summer air which a northerner can never know, and which makes the temperature here of 90° more pleasant and agreeable than that of 85° at the north. The constant gentle breeze by which we are fanned—the pure air which the lungs inhale so easily—and the inviting shade in which the ease of earning our subsistence permits us to indulge, all unite to awaken the consciousness of present calm enjoyment which few other situations in life can impart. Our winters indeed are pleasant, and much praised by the invalids who yearly resort here—even more pleasant than our northern summers. But we complain of frequent and sudden changes of the weather. Yes, we complain; though the extreme winter range of the thermometer is between 50° and 82 or 3°; while the summer range at the north is from 32° to 100°. When the winds in winter are between east and south, which is perhaps two-thirds of the time, we are contented, and we lounge in our piazzas in thin summer clothing. But when the wind comes out of the north, then "stand by" for pinching cold. Woolen clothes become necessary, though some will shiver in their thin ones rather than change; and in the evening, perhaps half a dozen times during the winter, a cloak is very comfortable to sit in. Fire is quite out of the question. I have not seen that strange light in a dwelling since I left New-York in the fall of 1835. On these occasions the mercury ranges about 60° at its extreme depression. It has been known since the settlement of the island, *twice only,* to fall below 50°. And it has been known to rise, in summer, above 90°. So far this season it has not been above 85°.

I speak here of the temperature of Key West. Cape Florida is one degree further north, and of course is some colder; but no thermometer having ever been kept there, its exact temperature is not known. Neither am I satisfied whether frost has ever been seen there or not. It certainly has not on Key Biscaino, which helps form the bay, since the light house has been there, which is ten or twelve years. At all events, garden vegetables thrive there throughout the winter. While I was at the cape, in January, we had green peas, beans, corn, fresh potatoes, and other articles of the kind. Indeed planting and plucking, upon a limited scale, is in progress there at all seasons of the year; and the fruit trees exhibit their flowers, their green and their ripe fruit at the same time and almost at all times.

The title to a large portion of the land at the cape, as well as elsewhere in the territory, is yet unsettled. Before the cession of Florida to the United States, a tract of twelve miles square was granted by Spain to one Don Juan Arrambide, the south line of which passes east and west, through the mouth of the Miami river, about eight miles north of the principal entrance into the bay from the sea. This grant has been decided to be valid by the Superior Court for this district, having jurisdiction of such cases; but the United States have appealed from the decision to their own Supreme Court. When the appeal will be tried is uncertain—perhaps not within two or three years. No doubts, however, are expressed here that the decision will be comfirmed. Still this case will not determine *in whom* the title in fact lies—but merely whether or not it lies in the United States. In the mean time there is a suit pending in Chancery between three several parties, each of whom lay claim to the land under the said Spanish grant. This suit will probably be determined in the course of a year, when, it is believed, the land will be offered for sale, by the successful party, on some conditions to secure the purchasers against loss, in case the Supreme Court should decide against the validity of the grant.

This tract embraces the whole of the north end of Biscaino bay, and extends east and west from the sea to the everglade, including the whole of the Miami and its branches, Little river, Arch creek and the mouth of Rio Ratones, all emptying into the bay. South of the Miami, and stretching along the shore of the bay, lie three donation grants containing one square mile each, all owned by a resident.

With the exception of these grants, the title to the land is clear and undisputed in the government. But inasmuch as it has never been surveyed, nor brought into market, they who settle it must rely, for their title in future, upon their right of pre-emption. Such settlers are furthermore protected by an express provision of our Territorial Statute recognizing in them a property in the lands they thus possess, defensible, transferable, and subject to execution.

I propose in my next to treat of the soil and productions of the country, and the various means of subsistence for those who dwell there.

L. W. SMITH.

EXTRACTS.

From the New England Farmer.

Ashes—Milk—Bog.

We have the pleasure to present to the agricultural public the subjoined highly valuable communication; and acknowledge ourselves much indebted to the kindness of this intelligent and skilful cultivator for having at our request presented it. Our attention in passing on the road from Pawtucket to Providence had been always particularly attracted to the improvements going on on this farm, and the order and neatness which marked the premises. The last spring, on a visit to some relatives, we had the pleasure of examining the excellent management pursued at the establishment. The cultivator it will be seen from the style of address, is a friend. This most exemplary christian sect are always remarkable for their neatness and order, qualities which are so valuable, and produce so much comfort in life. "Thou shalt be neat and clean, and systematic and orderly in thy person and in all thy dealings" is a commandment, which if they have not actually added it to the decalogue, seems to have with them almost as high an authority. A slovenly Quaker is a "rare bird;" an anomaly seldom occuring. We cannot too much commend them for this. "Order is Heaven's first law." Neatness, as a friend was accustomed to remark, is next to godliness; it is essential to good manners and almost equally so to good morals: its opposite is certainly a violation of what are called the minor morals of society.

H. C.

North Providence, 6 *mo.* 4, 1838.

Respected Friend, Henry Coleman—I have never known more profitable results from the application of any manure to light and sterile soils, whether loamy, sandy, or gravelly, than from leeched or unleeched ashes. They have long been used in Rhode-Island with great success, especially in the growing of barley and clover, to which they seem peculiarly adapted. As evidence of the estimation in which they are held by the farmers of the Island, ten cents per bushel have been paid for them in Newport for the last twenty years and upwards, and though considerable quantities have been furnished from different places on the sea-board, the demand for them has always exceeded the supply. They are generally used at the time of seeding, spread on an even surface and harrowed in lightly with the grain and grass seed. The quantity varying from 50 to 100 bushels per acre.

In 1833, a lot of land falling under my management which had then recently been purchased at $30 per acre, seven acres of it and perhaps the least valuable part, which in my opinion never possessed fertility, though it is usually called worn out land, being a sandy plain, gravelly subsoil, were ploughed and rolled, in order to secure for the benefit of the crop what little vegetable matter had been turned under; about 1,600 bushels leeched ashes were then spread on the lot, and it was sowed with 10 quarts millet and 16 lbs. southern or small clover seed to the acre. The season proved dry and the seed took badly, the crop of millet was 10 tons by estimation, and was sold for $180. 19 tons clover were supposed to have been obtained the two succeeding years at four cuttings; this too was sold for $316. The clover having nearly all perished in the winter of 1835-6 it was pastured the season following, and last year 1,136 bushels ashes having been applied to it, it was again sowed with millet, and stocked as before with southern clover, 20 lbs. to the acre. The product was 13 tons millet, for which I credited the owner $221, retaining it for my own use. Like results have been obtained from similar treatment of the same description of soil in various instances, this not having been selected because the most striking, but because the amount for which the crops sold fixes their value, without knowing exactly the quantity produced, which in each case has been supposed. The labor bestowed on the lot was more or less blended with other business of the farm; it is therefore difficult at this period of time to ascertain the amount charged. I believe, however, it did not exceed the charge in the subjoined account.

Cost of land,	$210 00
" ashes for both dressings,	215 54
Seed for do.	41 25
Ploughing 10½ days,	21 00
Rolling 3½ do	7 00
Harrowing 3½ do	7 00
Carting outside furrows,	7 50
Sowing 3 days,	3 00
Carting and spreading ashes,	54 00
Cutting, curing, and housing 41 tons millet and clover,	123 00
5 years taxes,	2 10
Interest accruing on transaction,	46 00
	$737 39
Cr.	
By Produce sold, amounting to	$717 00
Value of pasturage,	15 00
Value of lot in its present condition,	385 00
	$1,117 00
	737 39
	$379 61

There is reason to suppose from present appearances that the lot in question will cut two tons clover this season per acre; it will therefore be seen that my valuation is not a high one. A repetition of the treatment it has received, would no doubt improve still more the texture of the soil, but I am inclined to think there might be a falling off instead of an advancement in the amount of its productions, by subsequent ashings. Should this be the case it would indicate a suitable condition for more permanent improvement by manuring.

There is but one instance in which I can make out the exact quantity of milk sold in a year. It amounts to 11,131½ gallons; this is exclusive of a supply for the family, and was produced by I suppose an average of 20 cows. There have been seasons when I think a larger quantity has been produced in proportion to the number of cows kept, but the manner in which my books have been kept, hardly ever specifying more than the amount received for the article sold, does not enable me to determine with accuracy the quantity sold in any other year. In the instance given the milk was disposed of to one person at a certain rate, which with the amount of sales being known determines the quantity. How much was used by the family is not known, probably not more than 300 gallons.

In regard to the bog there is yet but little to be said, a greater part of it being yet on the tide of experiment, whether successful or not, time will determine. The burnt part has hitherto been most productive. In 1835, ½ acre was pared, the turf burnt, and the ashes spread over the surface. The year following it was planted with potatoes, the crop paying for the land at $30 per acre and all expenses accruing from its improvement. Last year nothing was taken from it, it was seeded the latter part of summer, and now promises a large crop of hay.

Respectfully thy friend,
ADAM ANTHONY.

From the Genesee Farmer.

Different Systems of Farming.

Mr. Tucker—In the management of our temporal affairs, whatever presents itself to our minds in the most clear and distinct manner, as best calculated to promote our interests, we embrace the most cordially, and pursue the most thoroughly. The operation of this principle is manifested in all the events and pursuits of life. And if the question should be asked, 'Why is it that men do not universally adopt the most approved and enlightened systems in the management of their different avocations,' the answer must evidently be, that from want of proper information they are not equally convinced, by a clear and distinct perception, of the superior merits of any system but their own. And in no other business is the practical operation of this principle so manifest as in that of farming; where a great diversity of systems leads to as great a variety of results.

My purpose is to show that farming, in its great fundamental features, is one of the plainest and easiest things in the world, if we but take hold of it in the right way.

Let us first look at the different systems of farming in vogue among us. The longest tried, and most venerable, is that of *Skinning*, whereby the farm and the farmer become impoverished together. This system has yet many advocates in the land, who settle down on good soils, work it hard, and wear it out; then sell cheap, and go to the *west* and buy cheaper and better soils; wear that out, pull up stakes again, and again push off to the west. By this system, new countries are cleared up and settled, and a broader scope given to population; fulfilling the requirements of Scripture, "be ye fruitful, and multiply and replenish the earth." Another system, of a somewhat more modern date, is, *Let well alone.* This system is an innovation on the former,—it keeps the farm and the farmer in *statu quo*, or just as they were; upon the idea, that attempting to improve nature is warring against Providence—it keeps society stationary, as offering no inducements to emigration; the requirements of life are not multiplied, as wealth is not amassed and luxury induced; and population is kept uniform and steady. Another and still later system of farming is, *Improving*; whereby the soil is renovated, the crops more abundant, and the farmer is enriched. This is the latest innovation that has been made upon the old system of *Skinning*, and is antipode to it. It finds but few advocates yet, although its advantages are so superior; as it is hard to prove to men that they are and always have been blind. Men naturally incline to pre-conceived opinions, and do not willingly forsake them, as they are reluctant to acknowledge themselves in error; and their minds are consequently hardened against new impressions, however valuable, and advantages are forsaken which might have been easily secured. But with all man's attachment to old ways and notions, the *Improving* system of farming is gaining ground every day. It is true that this system is somewhat in advance of the times, as the ignorance of the mass of farmers does not permit them to see and appreciate the correct principles upon which it is based. But as its utility and soundness are every day more and more developed and extended, its advantages become more and more apparent; and if its *theory* be not misunderstood, its results being visible, its *precepts* will be adopted and applied.

I have said that farming is one of the plainest and easiest things in the world, if we but take hold of it in the right way; and having exhibited the different systems, *Skinning*, *Let well alone*, and *Improving*, with a brief view of their relative merits, it must be apparent that the latter is the best system of farming, and the right way of taking hold of it. Its advantages over the other systems, I have said, were, it improves the soil, enlarges the crops, and enriches the farmer; it moreover diminishes the relative labor, and affords support to a more dense population. These are advantages of no ordinary magnitude, peculiarly resulting from this system.

The principle upon which the *Improving* system of farming is based, is simply this—so managing the soil as to make it afford to the plants grown upon it, a full and sufficient supply of nourishment, to bring them to the highest degree of perfection; and so managing the plants cultivated, as to keep them in the most healthy state, that they may draw from the earth and the air the greatest amount of nourishment they can elaborate. This is the *Alpha* and *Omega* of this boasted and book-taught system. As different soils and crops require difference of management, I shall, for the purpose of illustrating the principles of this system, barely give a general outline of its features, upon which a fair estimate can be made with regard to its detail. First, and most important, the soil should be well enriched with *barn-yard manure;* whereby it will be made more friable, more pervious to the atmosphere and the roots of the plants, and less subject to be injuriously affected by drought and heavy rains;—manure, besides, affords the most permanent and important supply of nourishment to plants; and should be thoroughly incorporated with the soil, Another peculiarity of this system is *rotation of crops.* whereby the different constituents of the soil are all and equally taxed, and none of its energies left useless and inactive—this is an important consideration. Where the soil can be adapted to it, the root culture should be a primary object, to the full wants and consumption of the farm stock, as affording the greatest profits in the largest amount of animal sustenance, and leaving the soil in a good condition for small grains. Clover is another important crop; it is next to barn yard manure as a fertilizer and pulverizer of the soil, for which it should be ploughed under and permitted to rot. Other crops, as required, and adapted to the soil, following in rotation, with proper dressings of manure, will improve the soil, and yield golden harvests to the farmer—if he will go one step farther, and manage his crops as well as he has his lands. The plants cultivated should have the soil *all* appropriated to their use, by extirpating with the hoe, or otherwise, all weeds and other foreign plants; which, if permitted to grow, would absorb some of that nourishment from the atmosphere and the earth which would otherwise be taken up by the crops, in the more full and perfect development of their quality and quantity. As regards hoed crops, the surface of the soil should be stirred as often as practicable, but not so deep as to injure the roots; leaving the surface as near as may be, the same that it was when the seed was put into the ground. Nature having indicated the proper depth of the roots in the soil, it can neither be increased or diminished but to the disadvantage of the plant.

These general rules, acknowledged correct and important by all who have tried them, could they be reduced to general practice, would have a most salutary influence upon the farming interests, and upon the interests of every other class in society. These rules are simple and easily applied. Always keeping one purpose in view, viz: making your crops healthy, by attending properly to them, and giving them enough to eat, and the great end of agriculture is attained. It is true, that farming requires intelligence to conduct it with pleasure and profit, as what occupation does not? The science teaches us the way of forcing nature to shower her blessings upon us in greater profusion—it enables us to grasp the cornucopia with our own hands, and to pour out its treasures into our own laps. E. W.

Pittsford, June 6, 1838.

From the New-England Farmer.

I have great pleasure in presenting the subjoined statement to the agricultural community. It came to hand some time since, but its publication has been delayed in the expectation of receiving the reports referred to from the other families. Like every thing else which comes from this worthy people, the report is well drawn up; and will be read with much interest. It is impossible I believe to find more striking examples of neat, careful, exact, and skilful husbandry than are to be found in these industrious and temperate communities wherever they are planted in any part of our land. H. C.

Report of the Farm of the United Society called Shakers in Canterbury. First Family.

No. of acres.	Live stock.
Tillage 25 to 30,	Horses 10,
Eng. Mowed 100,	Oxen 10,
Wet Meadow 40,	Cows 40,
Pasture 500,	Sheep 300,
Orcharding 30,	Swine 40,
Wood, Waste, &c. 500,	Young Neat Stock 10,

Soil, Loamy; Dry; Rocky; Hilly.

Shaker Village, Merrimack co. N. H.
Oct. 30*th*, 1837.

Henry Coleman—*Esteemed Friend*—I have annexed a sketch below in answer to your inquiries with as much exactness as practicable, as I had to obtain it from those who had the experience of *actual experiment*, as we have never kept any record of any such thing, hence the difficulty of obtaining the desired information. If any thing that I have written on the subject will be of use or interest to you, you are heartily welcome to the same; and were it not for the pressure of business and the limited time, I should have been glad to have given you a more lengthy and minute report. With much respect, your friend,

WILLIAM WILLARD, for and in
behalf of the first family at Canterbury, N. H.

Amount of hay usually cut is from 140 to 250 tons per year, in this (first) family, exclusive of the other two families, who have made out (or will) their memoranda separate, as you will perceive, viz: in year 1835, 140 tons—1836, 226 tons—1837, 133½ tons.

We have one field of 12 acres, another of 10 acres, and part of another which has not been ploughed for upwards 30 yrs. In one of said fields we cut 32 tons to 12 acres the first mowing, or 2 8-12 tons to the acre, besides the second crop. We apply top dressing once in a few years and roll the same in by means of a roll filled with iron pikes, sharp, 4 or 6 inches long, drawn by oxen or horses.

Wheat.—Our soil not being well adapted to wheat we can say but little about it, as we raise but little; generally not more than from 35 to 50 bushels per year, the most that we ever raised per acre was 40 bushels which is an extra crop for us.

Corn.—We raise but little, from 50 to 70 bushels per acre. On a neighboring farm, 12 miles distant, was raised a few years since 112 bushels 5 qts. to the acre—was planted in hills, not dunged in the hills, but spread on the surface and ploughed in, which we think the best way.

Oats.—Sow annually from 10 to 12 acres, yield on 3 acres in year 1836, 80 bushels per acre—average yield of 10 acres 60 bushels per acre, with exceeding heavy straw; the land was of good quality and prepared in the usual way.

Potatoes.—We usually raise from 2,000 to 2,500 bushels annually. The largest crop we have raised was in year 1833, which was 400 bushels per acre, (common potato) the land had no extra preparation.

Turnips.—Raise from 4 to 600 bushels annually, of the common English and Ruta Baga. In 1836 raised from 7 to 800 bushels of English, have raised from 4 to 600 bushels of Ruta Baga per acre, consider them good for sheep, cows, and beef cattle.

Flax.—Raise but little of this article of late years. In 1822 raised the greatest quantity, which was 900 lbs. Flax from 5 pecks sowing on 1¼ acres of ground, prepared in the usual way.

Carrots.—We annually raise more or less of these, some yrs. 1,000 bushels: one year raised 800 bushels per acre.

Peas.—In year 1836 sowed on one piece 3 pecks, yield 16 bushels.

Beef.—The largest beef we have raised weighed 1400 lbs; fattened on carrots, potatoes, with but a small quantity of meal.

Pork.—There are a diversity of opinions in regard to the best and most expeditious manner of fatting hogs. We have tried perhaps as many different plans as we have had different hands to fat them. Some will say all corn, some part corn with potatoes, &c. We for 2 or 3 years have adopted the plan of gathering our apples into our hog-house instead of the cider mill, and feed them upon boiled apples, potatoes, and pumpkins, with the addition of a small quantity of meal, to be increased as the killing time draws nigh, and under this management we have never known our hogs to thrive better or faster. Another method we have tried, (when fed with corn.) Take a tight barrel, fill it half full of corn, pour boiling hot water until the corn be covered, let it stand a few hours, and the barrel will be full of corn, and very little if any water to be discovered; this answers when at a distance from mill, and is better than dry corn without grinding; but we think it will not fat so well as made into proper meal. We had 20 hogs fatted on meal, began 1st day of August, one of them killed last of October, weight 400 lbs; the other 19 killed 23d December, average weight of the 19, 480 lbs; the meal mixed part of the time with skimmed milk, mixed as dry as possible; gave them at first 1 quart of meal per day each, from that to 3 quarts per day each, and a time before they were killed they refused 3 quarts per day; have frequently had hogs weigh 600, fattened on potatoes and meal. Had one small shoat, very small size, taken away from the rest and fed on one pint of corn per day, with meadow hay, milk, and wash, from September to December, weighed when killed 500 lbs; this pig when separated from the rest was the smallest in the lot. We are decidedly in favor of apples for hogs and cows. We take them promiscuously as they grow, without regard to their being sweet and sour.

Wool.—Average number of lbs. of wool for Merino bucks, from 7 to 9 lbs; have sheared 10 lbs.; average number of lambs per year from 150 to 190 Merino.

Breed of Cattle.—The Durham Short Horn for cows and stall, for labor we have not had sufficient experience of them.

The most profitable article for cultivation are the potato and carrot for fatting hogs and beef, and for milch cows.

Lime as a Manure.—We have used lime as a manure to good advantage; it restores and replenishes the soil that is apparently worn out. We air slack it and spread it and plough it in. Gypsum we have made no satisfactory trial of.

We suggest the idea to all that can obtain it, the use of *saw-dust* as a litter for hogs, horses, cows, oxen, &c. We have tried it for years; litter all our horses with it, like it much better than straw. We in the spring haul the saw-dust from the mill and deposite it in a convenient place to be got at, at night throw half a bushel or more under each horse, taking care to scrape out all that is wet beforehand, and in the morning it mixes in with the manure, goes into the heap, absorbs the wet, and forms a compost, and in a similar way for hogs, oxen, cows, &c.

Another effectual experiment I have tried, which is, before putting a quantity of oats into a close bin, (as we do frequently 7 or 800 bushels,) to throw or sprinkle fine salt among them; this prevents them from heating, also makes them relish better, and finally keeps them entirely free from must.

Horse Rakes we use—when constructed on the right principle are a great labor saving machine; we usually rake at the rate of 4 acres per hour. The same may be said of threshing mills. We have one of our own construction, a description of which would exceed the limits of this sheet. We usually thresh from 100 to 150 bushels per day; at the same operation it is winnowed and cleaned already for putting up.

The report of the second family, I have as yet been unable to procure.

Amount of butter for 10 yrs. past, 2,436 lbs. per year.
" cheese " " 3,265 " "

Hints for Prevention of Disorders in Horses.

Chiefly taken from Messrs. Clarke and White's valuable Treatise on Horses.

STABLES.

Stables should be lofty, light, and airy, and should never contain more than six or eight horses. They are in general kept too close and hot.

Too much clothing also is usually put upon the horses, which thus become so tender, that they catch cold upon every slight exposure to a cool air.

The doors and windows of stables should be thrown open when the horses are out, but care must be taken that a cold current of air does not immediately blow upon them when in the stable, particularly if they are heated.

It is a bad practice to allow herses to stand upon litter in the day time, except they are unwell or fatigued.

FOOD.

The quantity and quality of a horse's food should invariably be regulated by the exercise and fatigue he has to undergo; high feeding, without proportionate work, produces half the disorders to which horses are subject.

Good hay is of much consequence to horses engaged in active exercises; but it should be given in small quantities during the day; and when owing to bad weather, the horses cannot be exercised, they should be stinted both in their hay and corn; and a bundle or two of clean wheat straw may be put before them. All grain given to horses, would be more nutritive if bruised in a mill and mixed occasionally with chopped straw. Carrots are a most wholesome food, and of all roots, rank next to corn in point of nourishment. They are particularly serviceable when a horse's wind is affected.

When horses are first taken from grass they should be gradually brought to a dry diet by giving them carrots, lucern, bran mashes, &c. with their hay. After a few days a small quantity of oats may be given, and the feed increased by degrees till they come to their full allowance. They should likewise be put into a cool stable, and have plenty of walking exercise. If such precautions were attended to, a great saving might be made, both of physic, and the horse's constitutions.

WATER.

Pond water, if it lie on a clay bottom and be sweet, agrees best with horses; hard water may be improved by throwing some chalk or clay into it, and exposing it in cisterns to the open air.

It is proper to let the water, intended for the horses, stand for some hours in pails in the stables before it is used.

Water should be offered to horses frequently; they would then never drink large quantities of it at a time, which is particularly hurtful to them when heated by exercise. It is a good and safe plan when travelling, &c. always to mix hot water enough with their cold to take off the chill.

EXERCISE.

A horse's exercise should be proportioned to his strength, manner of feeding, and the labor required of him. He ought, however, to have at least two hours of daily exercise.

Horses should not be ridden fast after having been newly fed and watered. A fat horse requires a long course of moderate exercise, before he can safely be put to trot, which is violent.

It should be a general rule to ride a horse slowly at the beginning of a stage; afterwards increase the pace, and slacken it again a mile or two before the end of it, so as to bring him tolerably cool into the stable.

If horses come in very warm, they should be walked about gradually till cool, their feet should then be picked, and all dirt and gravel carefully washed out. In hot weather, washing their legs is proper, but they should always be well rubbed afterwards. In winter, cold water is injurious to the heels, and apt to bring on swelling and the grease.

Horses should on no account be permitted to stand uncovered in the stable, much less at the stable doors after being much heated, except the weather be very warm. Road horses should in the middle of a long stage have half a pail of water mixed with a little oatmeal; and on a journey, if no other corn but what is soft and new can be procured, oatmeal just moistened with water or some coarse bread, should be given in preference to such corn, which is extremely unwholesome. If a horse grow costive, let him have some mashes of scalded bran or malt. If he have any difficulty in staleing only, an ounce of nitre may be given in his food for a few nights.

Should he be seized with a violent fit of the gripes, let him be bled, back-raked, and have a glyster of three or four quarts of water gruel mixed with eight ounces of glauber or common salt.

The best instrument for giving a glyster is an ox bladder, that will hold two or three quarts, tied to the end of a wooden pipe about fourteen inches long, one inch and a half diameter where the bag is tied, and of a gradual taper to the extremity, where the thickness should suddenly increase, and be rounded off at the point, and made as smooth as possible. The hole through the pipe may be made sufficiently large to admit the end of a common funnel for pouring the liquor into the bag; no other force is requisite to throw it up, than the holding the bag a little higher than the level of the pipe. If in consequence of violent inflammation and pain, and opiates should be necessary, a table spoonful of laudanum may be given in a pint of water.

Should a horse be touched in his wind, be very careful that he has only moderate quantities of food and water at a time. Two spoonfuls of tar mixed with the yolk of an egg given in a morning fasting will be of great service to him when travelling. In hot dry weather, it is useful to stop horse's feet at night with a mixture of soft clay and cow dung, and to moisten them frequently with water.

FRICTION.

The currying, brushing, and rubbing down horses is of great importance, not only to their coats, but also to their general health; when these operations are neglected, or slightly performed, an obstruction takes place in the pores of the skin producing mange, &c. and the hair instead of being smooth and shining, stares, and stands on end. Nothing tends so much to prevent grease and swelling of the legs, as frequent hard rubbing and carefully cleaning the heels.

TRIMMING.

The ears of horses are covered with a short down in the inside, mixed with larger hairs, to prevent cold air, rain, dust and flies from hurting the internal ear. The trimming therefore this part, is very prejudicial to the horse.

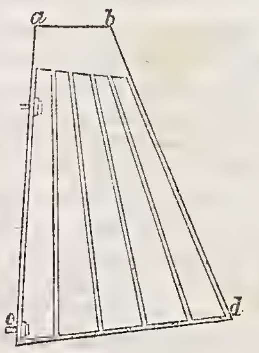
Harvesting Potatoes,

Where the crop is large, is a slow and tedious operation; and when the plough is employed to abridge the labor, great loss often ensues, from the gathering being imperfectly made. Our fellow citizen and friend, Joab Center, of Hudson, contrived a plough two years ago, to facilitate this process, which we were told worked well; but as we never saw it perform, we have not felt authorized to speak of its merits. In the mean time, Mr. Lawson, of Edinburgh, seedsman, has invented a mould board, which may be attached to a common plough, we believe very much on the model of Capt. Center's. We give drawings of this below, together with Mr. Lawson's description of its structure and operation, and in time for those who wish to profit from the improvement, to give it a fair trial the coming autumn. We take the article from the Quarterly Journal of Agriculture.

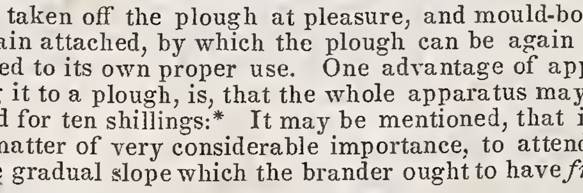
"The machine I am about to describe, and which I would call the *potato-raiser*, besides doing its work more efficiently, a matter of great importance, saves all the *hacking*, and consequently all the expense of the manual labor which that operation incurs, for it throws the greater part of the potatoes on the surface of the ground, and at once enables the women employed for that purpose to gather them by hand into baskets.

"The shortest description which, perhaps, can be given of this machine, is to say that you take a common plough, *deprived of its mould-board*, the share and coulter remaining in their usual position, and in room of the mould board, attach an instrument similar to that which is represented in cut in the margin, and which consists of malleable iron-bars, joined together in the form of a gridiron or brander. It is 26 inches long from *a* to *c*, 18 inches from *c* to *d*, and 27 inches along the line from *d* to *b*, and the breadth *a* to *b* 5 inches. It is attached by the edge *a c* to the furrow side and stilt of the common plough by screws, the fore part, *a b*, resting immediately behind the share, like the common mould-board; the angle at *c* is set about 8 inches above the sole of the plough; the edge *c d* slopes *downwards* in a convex curved form until the point *d* is about 4 inches above the level of the sole. The brander is fixed by screws at *c f*, and one may be required at the solid part *a b*, but these fixtures must be regulated by the construction of the plough. The following cut represents a plough mounted as a potato-raiser in the manner here described. The brander can be taken off the plough at pleasure, and mould-board again attached, by which the plough can be again applied to its own proper use. One advantage of applying it to a plough, is, that the whole apparatus may be had for ten shillings:* It may be mentioned, that it is a matter of very considerable importance, to attend to the gradual slope which the brander ought to have *from* the landward edge. Were it to lean *inwards*, or towards the land-side of the plough, it would do its work but imperfectly.

[Fig. No. 44.]



[Fig. No. 45.]



"The potato-raiser is drawn by one pair of horses, in the same manner as a common plough. In working it, the ploughman inserts the machine into the potato-drill, so as to have the whole of the potatoes on the *right-hand* side of the machine. He then proceeds along the drill, splitting it up in the common way. The earth is thus thrown to the right hand side, and the potatoes lie scattered on the surface of the ground behind the plough.

"Women provided with baskets follow the machine. They gather the potatoes into the baskets, and throw the stems of the potatoes upon the drill which lies to the right-hand of the drill from which they are gathering the potatoes. The reason why the potato stems are thus removed, is, that, as soon as the potatoes which lie on the surface are gathered, the machine returns, and again proceeds as before, through the part of the drill in which the potatoes lay, still turning the earth to the right-hand side. This *second* operation raises to the surface any stray potatoes which the first may not have turned up, and the potatoes raised by the second operation, are immediately gathered by the women who attend for that purpose. This second operation may be delayed till about twelve drills are turned over by the first operation, and the potatoes gathered. The machine may then be put through these twelve drills the second time. By this there will be a saving of labor, as a smaller number of women will gather the potatoes raised by the second operation. If the stems of the potatoes be very *strong and luxuriant*, a few women may be put along the drill to pull them out of the ground, at the same time gathering up any potatoes that may adhere to, and come along with, the stems. If this be done, the potato-raiser will turn up the greater part of the potatoes by going *once only* through the drill; in going *twice* it will do it in the most satisfactory manner. A man with one pair of horses will thus pass over the ground as quickly as with a common plough.

"These two operations are all that are required to raise the potatoes to the surface, the land being afterwards harrowed in the common way. The potato-drills ought to be of the ordinary breadth, so as to give the machine room to work. Very narrow drills do not suit it.

"I may mention, that the farm on which the potato-raiser has been used, is a light loam, and in that soil it performs its work in a very satisfactory manner. It pulverizes the soil in an extraordinary degree, and scarcely leaves a potato in the soil. I have never before been able to clear my fields of potatoes so effectually as by this machine, or at nearly so small an expense."

Dr. Dana's new mode of Analyzing Soils.

[*From Professor Hitchcock's Geological Report.*]

1. "Sift the soil through a fine sieve. Take the fine part; *bake* it just up to browning paper."

2. "Boil 100 grains of the baked soil, with 50 grains of pearl ashes, saleratus or carbonate of soda, in 4 ounces of water, for half an hour; let it settle; decant the clear; wash the grounds with 4 ounces boiling water; throw all on a weighed filter, previously dried at the same temperature as was the soil, (1); wash till colorless water returns. Mix all these liquors. It is a brown colored solution of all the soluble geine. All sulphates have been converted into carbonates, and with any phosphates, are on the filter. Dry therefore, that, with its contents, at the same heat as before. Weigh—the loss is *soluble geine.*"

3. "If you wish to examine the geine; precipitate the alkaline solution with excess of lime water. The *geate* of lime will rapidly subside, and if lime-water enough has been added, the nitrous liquor will be colorless. Collect the geate of lime on a filter; wash with a little acetic or very dilute muriatic acid, and you have geine quite pure. Dry and weigh."

4. "Replace on a funnel the filter (2) and its earthy contents; wash with 2 drachms muriatic acid, diluted with three times its bulk of cold water. Wash till tasteless. The carbonate and phosphate of lime will be dissolved with a little iron, which has resulted from the decomposition of any salts of iron, beside a little oxide of iron. The alumina will be scarcely touched. We may estimate all as *salts* of lime. Evaporate the muriatic solution to dryness, weigh and dissolve in boiling water. The insoluble will be *phosphate of lime.* Weigh—the loss is the *sulphate of lime;* (I make no allowance here for the difference in atomic weights of the acids, as the result is of no consequence in this analysis.)"

5. "The earthy residuum, if of a greyish white color, contains no insoluble geine—test it by burning a weighed small quantity on a hot shovel—if the odor of burning peat is given off, the presence of insoluble geine is indicated. If so, *calcine* the earthy residuum and its filter—the loss of weight will give the insoluble geine; that part which air and moisture, time and lime, will convert into soluble vegetable food. Any error here will be due to the loss of water in a hydrate, if one be present, but these exist in too small quantities in 'granitic sand,' to affect the result. The actual weight of the residuary mass is 'granitic sand.'

"The clay, mica, quartz, &c. are easily distinguished. If your soil is calcareous, which may be easily tested by acids; then before proceeding to this analysis, boil 100 grains in a pint of water, filter and dry as before, the loss of weight is due to the *sulphate of ime*, even the sulphate of iron may be so considered;

---

* For the sake of those who desire to fit up ploughs in this manner, it is desirable that the strength of the iron of the brander had beeen particularized. We conceive the external frame should be five-eighths of an inch square, the internal bars one half inch diameter.—*Editor.*

for the ultimate result in cultivation is to convert this into sulphate of lime."

"Test the soil with muriatic acid; and having thus removed the lime, proceed as before, to determine the geine and insoluble vegetable matter."*

Sources of Geine or Vegetable Nutriment.

[*From Prof. Hitchcock's Geological Report.*]

Having now pointed out the situation and value, so far as known, of all the calcareous deposites in the state that can be applied to agriculture, and of other substances whose action on soils is somewhat analogous to that of lime, the next grand inquiry is, whether there are any sources in the earth from which additional quantities of geine can be obtained, or matters convertible into geine. I pass by the whole list of common manures, presuming that they will be fully discussed by the Agricultural Surveyor. And I shall merely notice the natural sources of vegetable nutriment within our limits.

PEAT SWAMPS.

The peat swamps of New-England have become a vast repository of organic matter, which is, and has been for ages, increasing. In addition to the larger vegetables, which, as they die, fall and are enveloped in the soft matter on which they grew, there is a thick mat of moss, which—especially the sphagnum—continues to flourish at the upper part while the lower part dies and decays. In favorable circumstances as to wet and temperature, this mass of vegetable matter becomes converted into peat. Only a small part, however, of what is thus accumulated, becomes peat of such a character that it answers well for fuel. Often it is too much mixed witn mud to be easily burnt, and sometimes the vegetable fibre is scarcely changed. Yet the whole of it is capable of being converted into vegetable nutriment. And I am convinced, from all that I have seen and heard, that Massachusetts contains enough of this geine and vegetable fibre in her swamps, to render all her fields fertile for centuries. In other words, here is an exhaustless source of geine. Some of it is already in a soluble state; and therefore the black matter from swamps, is rarely spread upon soils without producing some benefit. Yet for the most part the geine is in such a state as to require some chemical change before it will become soluble nutriment, fit to be absorbed by roots. It is an important inquiry then, what is the best mode of accomplishing this change. This has been attempted, first, by mixing the peaty matter with good manure in alternating layers, and suffering them to ferment for a long time, the peat being in much the greatest quantity. Secondly, by mixing it in a similar manner with lime; and thirdly, by mixing it with alkali, or some compound containing alkali. The principles respecting geine which have been advanced in this report, will probably enable us to decide as to the preference to be given to any one of these methods. And here I have it in my power to give the opinion of Dr. Dana, whose remarks I am always happy to substitute for my own, on a subject with which he is so familiar, and which he has done so much to elucidate.

"The fact," says he, "that peat or turf is very soluble, in alkali, seems not to be known among our farmers. The usual practice of mixing lime with peat or turf is decidedly the worst which can be followed. The geine which constitutes a large part of peat bogs, forms with lime a compound little soluble in water, requiring at least 2000 parts of water to one of geate of lime: and if the compound has been dried and sun-baked, a still larger portion of water is required: it becomes, in truth, almost insoluble. With alumina, geine forms a compound still more insoluble than with lime; and though the vegetable matter in combination with these earthy bases, is actually absorbed by the roots of growing plants, still the geine is in a state much less favorable than when in combination with alkali. Mix ley of wood ashes with peat, and we form a dark brown vegetable solution: the alkaline properties are completely neutralized by the geine, and very often ammonia escapes from turf when treated by caustic alkali. When we add, that this geine absorbs and retains nearly its own weight of water without seeming moist, it is evident, that with the use of ley or wood ashes, the value of peat as a manure will be very much increased."

I will only add, that in my opinion it would be very desirable to have a series of experiments performed by a practical chemist upon the different varieties of our peat, and especially upon the best mode of converting it into soluble geine. Since by the old methods of analysis the different varieties of peat would be found to differ from one another only in the quantity of organic matter which they contain, I supposed it would be useless to analyze them, and therefore did not collect specimens of the peat and other vegetable matters that occur in our swamps. The doctrines respecting geine put a new aspect upon the case, and lead me to regret that such a collection was not made. The labor of doing it now, however, is small; and when it is considered what an immense mass of organic matter now lies useless in our swamps, while the fields around them yield but a scanty crop, and that the chief reason why our farmers make so limited a use of this manure, is, that they find it difficult to convert it into soluble nutriment, I sincerely hope that the government will do all in its power to bring into use this important part of our fossil resources.

MARSH MUD.

Every intelligent farmer probably knows, that this substance forms an excellent manure; although I apprehend it is employed far less than its value demands. An intelligent farmer in Maryland states, that he "deems it more valuable than barn-yard manure;" and that "it never failed in any application he had made of it." He also prefers it to marl, because "it is more accessible, its effects are quicker, and much more can be done in the way of improvement for the same money." At the same time he confesses, that the permanent advantages of marl are much greater; and thinks that marl and marsh mud will both be improved by combination.* This last remark appears still more important, when we ascertain what it is that gives an agricultural value to this substance. The fact is, it sometimes contains a large quantity of geine, and sometimes but little, while the quantity of the salts of lime, soda, and magnesia, is rather large; so that sometimes a mixture of marl will be of service, and sometimes not. The following analysis of a few specimens of marsh mud, both in the ordinary way and by Dr. Dana's method, will show us, I think, what it is that constitutes its fertilizing power, and afford some useful hints as to its application.

Analysis in the dry way by Alkali.

Number.	Locality.	Water of Absorption.	Organic matter.	Silica.	Alumina.	Oxide of iron	Lime.	Magnesia.	Salts soluble in water.	Sulphuretted hydrogen and loss.
135	Newburyport, ...	3.2	3.3	68.1	14.7	7.4	2.0	0.8	0.2	0.3
136	Medford..................	9.5	12.5	50.95	14.9	8.15	1.1	0.2	0.6	2.1

Analysis by Dr. Dana's Method.

Number.	Locality.	Soluble Geine.	Insoluble Geine.	Sulphate of lime.	Phosphate of lime.	Granitic sand.	Specific gravity.
134	Cambridge, ...	13.0	7.4	2.3	0.4	67.9	1.92
135	Newburyport, ...	1.5	0.1	3.0	0.5	95.1	2.52
136	Medford, ...	7.5	5.6	2.6	0.3	84.0	1.92

A substance so rich in geine, or salts of lime and soda, or in both, as the above analyses show, cannot but prove a fertilizer of the soil if spread upon it. If a soil be quite poor, those varieties should probably be chosen that contain the most geine; and this can be judged of by their comparative lightness when dry; the lightest abounding most in organic matter. But if the soil already contain a good deal of inactive vegetable matter, the varieties that abound most in salts will probably be most efficacious; though an additional quantity of geine can do no harm, and may do much good. If marsh mud be applied at random, it is not strange that varieties of it, almost destitute of geine, should be sometimes put upon exhausted soil, and that no good effects should follow. Hence the necessity of some fixed principles to guide the farmer. And since Massachusetts contains so much sea board, and so much land near the coast that may be benefited by this substance, a correct mode of applying it is of great importance.

Depend upon it, that if you do not fulfil what nature intended for your fate, you will be a morbid misanthrope, or an indolent voluptuary—wretched and listless in manhood, repining and joyless in old age.

Young Men's Department.

Hints to Young Farmers.—No. 10.

GOOD AND BAD LUCK.

We are in the daily habit of hearing the casualties and misfortunes of life, and particularly in the operations of the farm, ascribed to *bad luck;* and on the contrary, of hearing the blessings, comforts and enjoyments of life imputed to GOOD LUCK—as though these things were casual, and did not depend upon the discreet or indiscreet conduct of those whom they befall.

If we will but scan this matter properly, we shall be convinced, that our good and bad luck most generally comes through our own agency; and that we are in a great measure left to choose our own fortunes in this matter. The faithful practice of known duties with a due restraint upon our baser passions, seldom fails to insure GOOD LUCK;—while indolence, extravagance, the lack of probity and good will to our fellows, are almost the certain precursors of BAD LUCK. And even though our crops may grow, from the exuberant bounty of nature; and although our patrimonial wealth may extort for us the fickle applause and sycopancy of the multitude, the pleasures which they afford are unstable, and are not to be put in comparison with those which result from a course of prudent industry and rectitude of conduct—from a consciousness of having performed, and of performing, the high duties imposed upon us, to our families, to society, and to our Creator.

Let us trace some of the instances of good and bad luck, in the business of the farm, to their palpable causes.

The diligent farmer, who personally superintends his business—who rises before the sun, *sees* that his laborers are at their appointed business, that his farm stock are in condition, his implements and fences in order, and his work timely and properly done, is pretty certain of enjoying a round of *good luck* in all his farming operations. He will have good cattle, good crops, and good profits—and, if he takes care to bring up his sons in the ways of their father, he will have good luck with his family.

On the other hand, look at that man who gossips away a portion of his time at public houses, at political clubs, and among his neighbors—and who trusts the management of his affairs to the discretion and fidelity of others, and ten to one but you find him an heir to *ill luck;*—that his land is annually becoming poorer, his crops lighter, his cattle diminishing, his fences and his buildings dilapidating, his children idle, and perhaps dissipated, and his fortune going to wreck. Who does not see, in such a man, a fountain of *bad luck.*

Our young readers have most of them, perhaps, heard of the *bad luck* that befel the man who neglected, in time, to get a nail in the horse shoe: the shoe came off; the horse became lame, and ultimately died—so that the owner lost his horse for want of a nail. The same *bad luck* attends him who neglects his fences: a rail or a board is down; cattle get in and destroy his crops, and he is obliged to buy bread for his family. The drone too, is generally late with his work—he plants and sows late—and suffers the harvest to waste in the field, before his crops are gathered or housed.

The diligent farmer destroys the weeds that rob his crops, and the bushes that uselessly encumber his grounds: he carefully economises and applies his manures, destined to feed his crops, and keep up the fertility of his soil; and he brings the best portion of it, though naturally wet and unproductive, into a productive state, by a system of judicious draining. All these are certain precursors of *good luck.*

Now mark the farmer of almost inevitable *bad luck* upon that farm down yonder, who, although in the harvest time, is from home, gone to attend a petty law-suit, in which he is a party. Look at the fences, the buildings, the bushes, the weeds, the swamps, the cattle, the crops—at every thing. Do they not all betoken *bad luck?*—and speak in language not to be misunderstood, that the unfortunate master is going *down hill?*

We have one other suggestion, which we may even extend to the fair. Idleness is the parent of tattle—of mischief. Now the man or woman who attend to their own business as they ought, have neither time nor disposition officiously to intermeddle in the domestic concerns of their neighbors—they have no interest in sinking the reputations of others—but would rather raise them to their own level. Their habits, therefore, tend to diffuse *good luck* to all around them.

Chemical Catechism—Chapter IV.

OF WATER.

What is water?

Water is a compound, consisting of hydrogen and oxygen.

In how many states do we find water?

In four: solid, or ice; liquid, or water; vapour, or steam; and in a state of combination with other bodies.

---

* In applying Dr. Dana's rules given in the text, to the soils of Massachusetts, I found it necessary to adopt some method of carrying forward several processes together. I accordingly made ten compartments upon a table, each provided with apparatus for filtering and precipitations, also 10 numbered flasks, 10 evaporating dishes, and a piece of sheet iron pierced with ten holes, for receiving the same number of crucibles. I provided, also, a sheet iron oven, with a tin bottom large enough to admit 10 filters, arranged in proper order, and a hole in the top to admit a thermometer. The sand bath was also made large enough for receiving the ten flasks. In this manner I was able to conduct ten processes with almost as great facility as one could have been carried forward in the usual way. *Prof. Hitchcock.*

* Farmer's Register, July 1834; p. 93.

What is the most simple state of water?

That of ice; because water contains a larger portion of caloric. (*a*)

How do we define vapour?

Vapour is water combined with a still greater quantity of caloric. (*b*)

What are the properties of vapour?

Vapour, owing to the large portion of caloric which is combined with it, takes a gaseous form, acquires great expansive force, (*c*) and a capability of supporting enormous weights; whence it has become a useful and powerful agent for raising minerals of all kinds, and even water itself, from deep pits, and for other very important purposes. (*d*)

In what proportions are oxygen and hydrogen combined to form water?

Water is composed of 88 parts by weight of oxygen, and 12 of hydrogen, in every 100 parts of the fluid.

How is it known that water is a compound substance?

Several methods have been contrived whereby water may be decomposed, and the exact proportion of its constituent parts ascertained.

Do you know any of the methods of decomposing water?

Yes, there are several: it may be done by forcing it through a tube over red-hot charcoal, by passing repeated electrical shocks through it, and also by means of the galvanic apparatus.

Does nature decompose water in any of her operations?

Certainly, by many: particularly by means of every living vegetable; all vegetables having the power of decomposing water, by a secret operation peculiar to themselves. Fish, in general, and all cold-blooded amphibious animals, we have reason to think, are endowed also with the same faculty.

For what purpose are vegetables endowed with this power of decomposing water?

They combine part of its hydrogen, as well as of its oxygen, with the carbon of the atmosphere and of the soil, to form the vegetable compounds, oil, wax, gum, resin, sugar, &c.; while the superfluous oxygen is abundantly evolved by the leaves;

> "Killing infectious damps, and the spent air
> Storing afresh with elemental life." (*e*)

Can you recapitulate what has hitherto been detailed of the nature of oxygen?

Yes: oxygen is the basis of vital air, as well as one of the constituent parts of water; it is the chief support of life and heat; and performs an important part in most of the changes which take place in the mineral, vegetable, and animal kingdoms.

What is hydrogen, the other constituent part of water?

Hydrogen is the base of that gas which was formerly called inflammable air, and is, when in the aeriform state, the lightest of all ponderable things.

Has any method been discovered of composing water by a mixture of oxygen and hydrogen?

Yes: there are several ways of doing this, so that the composition of this fluid is now ascertained beyond all doubt.

Do you know any of the methods which have been employed to form water by a mixture of its constituent parts?

If a mixture of oxygen and hydrogen gases, in proportion, be fired, the inflammation will unite the basis of the two gases, without separating the whole of their caloric, and water will be the product.

Is there any reason to suppose that water is thus formed in any of the great operations of nature?

Yes: it is probable that the torrents of rain which generally accompany thunder storms, may arise from a sudden combustion of hydrogen and oxygen gases.

How is the atmosphere furnished with this hydrogen gas?

Hydrogen is continually emanating from, and is the consequence of, every species of vegetable and animal decay or putrefaction; and it is also evolved from various mines, volcanoes, and other natural sources.

What is the specific gravity of water?

A wine-pint measure of water weighs rather more than one pound; and a cubic foot of water weighs about 1,000 ounces, or 62½ pounds avoirdupois. It is 825 times heavier than atmospheric air.

What change does water undergo in order to be converted into ice?

The atmosphere, when its temperature is sufficiently low, deprives the water of a certain portion of its caloric—crystallization then ensues, and the water solidifies and beomes ice. (*f*)

What do you mean by crystallization?

By crystallization, is understood the concretion of certain substances into regular forms, occasioned by the loss of a portion of their caloric.

To what substances is the term usually applied?

The term is generally applied to compound bodies of the saline kind, and to their separation in regular and peculiar figures, from the water in which they were dissolved.

You have said that ice is the most simple state of water: do you then imagine that water is naturally solid?

Near the poles water is eternally solid: there it is similar to the hardest rocks, and may be formed by the chisel of the statuary, like stone.

Is this great solidity of ice at the poles owing to its being frozen in such large masses?

The great solidity of ice at the poles is occasioned by the very low temperature of the circumambient air; for in very cold countries ice may be ground so fine as to be blown away by the wind, and will still be ice.

Is ice the only instance of water existing in a state of solidity?

No: water becomes still more solid in the composition called mortar and in cements, having parted with more of its caloric in that combination than it does in the act of freezing. (*g*)

What other instances are there of water taking a solid form?

Water is also combined in a state of solidity in many alkaline, earthy, and metallic salts, (*h*) both natural and artificial; and most of these, when deprived of it, lose their transparency and also their crystalline form.

What are the general and more obvious advantages which we derive from water?

Water is a necessary beverage for man and other animals; is perpetually used as a solvent (*i*) for a great variety of solid bodies; acts an important part in conveying nourishment to the vegetable world, and giving salubrity to the atmospherical regions; and lastly, by its accumulation in the ocean, affords a ready communication with distant countries;—the whole of which evidently teaches how provident the great AUTHOR of nature has been in his attentions to to the comforts and conveniences, as well as to the wants, of his numerous creatures.

(*a*) Ice at 32° must absorb 140° of caloric before it can become fluid; or such a quantity as would raise a body of water of equal bulk with itself from 32° to 172°. This may be very evident to a youth who has been taught the use of a thermometer, by the following direction:

"Take any quantity, by weight, of ice or snow at 32°, and mix it with an equal weight of water heated exactly to 172°. The snow instantly melts and the temperature of the mixture is still only at *thirty-two* degrees. Here the water is cooled 140°, while the temperature of the snow is not increased at all; so that 140° of caloric have disappeared. They must have combined with the snow; but they have only melted it without increasing its temperature. Hence, it follows irresistibly that ice, when converted into water, absorbs and combines with 140° of caloric. Water, then, after being cooled down to 32°, cannot freeze till it has parted with 140° of caloric; and ice, after being heated to 32° (which is the exact freezing point,) cannot melt till it has absorbed 140° more of caloric. This is the cause of the extreme slowness of these operations. There can be no doubt, then, but water owes its fluidity to its latent caloric, and that its caloric of fluidity is 140°.

(*b*) However long we boil water in an open vessel, we cannot make it in the smallest degree, hotter than its boiling point. When arrived at this point, the vapour absorbs the heat, and carries it off as fast as it is generated. Yet by continued heat, united with additional compression, both the expansibility and temperature of steam may be greatly increased; and some constructors of steam engines have lately availed themselves of this property, to augment the power and diminish the expense.

Owing to the quantity of caloric that liquids require to convert them into vapour, all evaporation produces cold. It has been remarked before, that an animal might be frozen to death in the midst of summer, by repeatedly sprinkling ether upon him. Its evaporation would shortly carry off the whole of his vital heat. Water thrown on hot bodies acts in the same way; it becomes, in an instant, converted into vapour, and thus deprives these bodies of a great portion of the caloric they contained.

(*c*) The expansive force of steam is found by experiment to be much greater than that of gunpowder. Some volcanic eruptions and earthquakes, it is supposed, owe their terrible effects to this power of steam; the water of the sea finding its way to subterraneous fires. In boiling oil, the workmen are very careful to prevent any water coming near it; for a single drop coming among it would instantly, by the excessive heat of the oil, be converted into vapour, and would force part of the oil over the sides of the boiler.

It is to the expansive force of steam, that the well known motion in water, called boiling, is to be ascribed. The vapour is first formed at the bottom of the vessel, and, passing through the water, causes that motion in it which we call ebullition.

(*d*) Steam is now employed in a vast variety of ways in the different manufactories of this kingdom. It is used with much economy of fuel in a great number of dye-houses in various parts of Great-Britain. It should, however, be remembered, that whenever it is intended to heat water by means of steam, the steam must not be thrown in upon its surface, but must be conducted to the *bottom* of the cold liquor before it can be disengaged, or the effect will not be produced, water having but little power of conducting heat *downwards*.

(*e*) When a living vegetable is moistened with water and the sun shines upon it, two very important operations are performed at the same time by the decomposition of the water which the sun's rays enable the plant to effect, viz; the plant is nourished by hydrogen, and the atmosphere is purified by the restoration of its oxygen.

(*f*) Water in freezing crystallizes in filaments, which are uniformly joined at angles of 60 and 120 degrees. The word *crystal* originally signified ice.

It is owing to the *expansion* of water in freezing, that rocks and trees are often split during intense frosts. According to the calculations of the Florentine academies, a spherule, or little globe of water, only one inch in diameter, expands in freezing with a force superior to the resistance of 13½ tons weight. Major Williams also attempted to prevent this expansion; but during the operation the iron plug which stopped the orifice of the bomb-shell containing the freezing water, and which was more than two pounds weight, was projected several hundred feet with great velocity; and in another experiment, the shell burst. The imbecility of man never appears so conspicuous as when he attempts to counteract the operation of laws which were designed by infinite beneficence for his preservation and comfort. The law in question is eminently important, and nature has made it unalterable.

(*g*) Though water takes a solid form in its various combinations, such as with lime, saline crystals, &c. we know of no method of compressing it when in a fluid state. The Florentine academicians filled a globe of gold perfectly full of water, and submitted it to a very powerfull press; but could not perceive that they were able to make it occupy a less space than it did at first. They gave it such a degree of pressure that at length the water exuded through the pores of the metal.

(*h*) If water be thrown on quick-lime, it will be retained by it with such force that nothing less than an intense *red* heat will separate it. In its combination with lime it becomes much more solid than when in the state of ice; which may be proved by direct experiment. Calcined plaster of Paris, in a pulverulent state, becomes quickly solid by mixing it with water. Saussure has proved that alumina, when mixed with water, retains a tenth of its weight of that fluid at a heat which would melt iron.

(*i*) It should be remembered, that all bodies which are soluble in water, form during their solution, a chemical combination with the water, and that solutions in water, are not mechanical mixtures.

Water is not only employed as a solvent for many solid substances, but has important uses in a variety of compounds. Besides imparting solidity to the classes of salts, it gives energy to the action of many of the acids, and is even necessary in their formation. Muriatic acid and nitrous acid gases are condensed so as to form liquid acids, merely by their union with water.

Beauty has little to do with engaging the love of women. The air, the manner, the tone, the conversation, the something that interests, and something to be proud of—these are the attributes of the man made to be beloved.—*Bulwer*.

PACKARD, VAN BENTHUYSEN & Co.

THE CULTIVATOR:

A MONTHLY PUBLICATION, DEVOTED TO AGRICULTURE.

I KNOW OF NO PURSUIT IN WHICH MORE REAL AND IMPORTANT SERVICES CAN BE RENDERED TO ANY COUNTRY, THAN BY IMPROVING ITS AGRICULTURE.—*Wash.*

VOL. V. NO. 3, WASHINGTON-ST. ALBANY, N. Y. SEPTEMBER, 1838. No. 7.

Conducted by J. BUEL, of Albany.

TERMS.—ONE DOLLAR per annum, to be paid in advance. Subscriptions to commence with a volume.

Special Agents.—L. & R. HILL, Richmond, Va.; BELL & ENTWISLE, Alexandria, D. C.; GIDEON B. SMITH, Baltimore, Md.; JUDAH DOBSON, bookseller, and D. LANDREITH, seedsman, Philadelphia; ISRAEL POST, bookseller, 88 Bowery, ALEX. SMITH, seedsman, P. WAKEMAN, office of the American Institute, Broadway, N. York; E. M. HOVEY, Merchants's Row, Boston; ALEX. WALSH, Lansingburgh, and WM. THORBURN, Albany, gratuitous agents. For general list of agents see No. 12, vol. iv.

The Cultivator is subject to common newspaper postage.

☞ Price of the published volumes, 50 cents per vol. stitched—the four volumes bound together, $2.75—bound in two volumes, $3—the four vols. bound each separate, $3.25.

THE CULTIVATOR.

TO IMPROVE THE SOIL AND THE MIND.

Rules and Suggestions in Husbandry.

We shall now proceed to give, agreeable to the promise in our last number, some rules and suggestions in husbandry, of general application, to enable farmers, and particularly novices in the art, to judge of the character and qualities of their soil—of its adaptation to particular crops—of the causes of its deterioration—and of the means of perpetuating its fertility; or, if worn out or impoverished, of restoring it to its pristine vigor. The facts and suggestions which we shall give are the results of our reading and our practice; and though they may not in all cases prove to be sound, we think that in the main they will be found to be so.

1. The essential elements of a good soil, are sand, clay, lime, and vegetable or organic remains. Magnesia, iron, and other matters, are often found blended with the preceding; but, in general, they are not considered as exercising a great influence on its fertility, except they exist in more than ordinary proportions.

2. The presence of sand, clay, and vegetable matter, in a soil, is deemed essential to all crops; and lime, in some of its forms, is considered indispensable to many crops, and particularly to wheat.

3. The presence of sand and clay is readily detected by the experienced eye; that of vegetable matter by the consistency and colour of the soil; and that of carbonate of lime, by drying a portion of soil, and pouring upon it some acid, having a stronger affinity for the base than the carbonic acid, as muriatic acid, or even strong vinegar—if it contains lime, effervescence will ensue—the proportion may be ascertained by the modes of analysis we have published.

4. Sand is the most essential in the earthy ingredients of a soil, and most preponderates; though where it exceeds eighty per cent, the soil is virtually barren. Clay is next in proportion; but where it greatly preponderates, the soil becomes stubborn, is hard to be worked, and more or less unproductive. Lime exists in the smallest proportion; and from two to ten per cent of the upper or tillable stratum is deemed sufficient for all the purposes of profitable husbandry. When in excess, it induces barrenness. A calcareous soil is considered conducive to the health of the neighborhood. Organic matter, that is, vegetable or animal, is indispensable in a soil. It is the food of plants. Yet even this is often found in excess, as in peat earth, and is often infertile till mixed with earthy ingredients, or brought in contact with fermenting materials.

5. When an excess is discovered to exist of sand, clay, lime or vegetable matter, the fault may be remedied by an admixture of the deficient element or elements. When one of the elements is found wanting, it may be supplied by art. Thus a load of clay upon an arid sand,—or load of sand upon a stubborn clay,—or a few bushels of lime, or marl, or ashes, upon a soil deficient in calcareous earth, are often of more ultimate service than a load of barn yard dung. But,

6. Both dung and lime are consumed by the growing crops; and if the crops are carried off, the land must be periodically replenished with these, or it will often become deficient in these material elements of fertility.

7. The sand and clay of the soil, may be likened, in their offices, to the stomach of the animal; the lime and salts to the gastric juices which assist to dissolve the food in the animal stomach—and to the condiments, as salt, pepper, &c. which we employ to stimulate and aid the organs and process of digestion;—and the organic matter in the soil, to the food itself, which feeds and nourishes the animal system.

8. If the crops grown upon a soil are permitted to rot upon, and return to it again, its fertility is not impaired, but improved. Nothing is lost, but something gained, from the fertilizing influence of the atmosphere. But when all the crop is carried off, and nothing returned, deterioration must take place—the vegetable food must undergo a continued diminution. This is a plain exposition of the cause of lands *wearing out;* and at the same time it explains the necessity of applying manures to keep up their fertility.

9. All the elements of a good soil being present, its fertility, and consequent profit, will in a measure depend upon its exemption from an excess of water, which, like fire, is a good servant, but a bad master. This excess may arise from spouts and springs bursting up from below, or from surface waters, where the ground is level, or nearly so, settling and reposing upon a tenacious subsoil, or from waters flowing from higher grounds. Hence the importance of draining. We do not know of any farm crop which thrives well upon a soil that is habitually wet, either upon its surface, or within the natural range of its roots. Water-meadows and rice profit by periodical floodings; but they are injured by habitual wetness.

10. Fertility depends much, also, upon the quality and properties of the subsoil. If this is defective, or comes too near the surface, its faults may be corrected, and the tilth deepened, by bringing it up, in small portions at a time, with the plough, to the ameliorating influence of the atmosphere, and by blending it with the upper stratum.

11. If a soil, under proper management, does not return good crops, or if the crops are found annually to diminish, it is a sure indication that there is a deficiency in one of the primary elements of a good soil, that the subsoil has a malign influence, or that there is an excess of water. It is the province of the manager to search out the cause of the evil, and to apply the proper remedy, be it lime, manure, drainage or a deeper tilth.

12. Grain crops are the greatest exhausters of the fertility of soils, on account of their narrow system of leaves, and the great quantity of nutriment they extract from it to mature their seeds. The remark extends to the narrow-leaved grasses, converted into hay, when they are permitted to ripen their seeds in the field.

13. Indian corn, tobacco and beans may be embraced in the second class of exhausting crops; for although they have broad leaves, and are supposed to derive much of their nourishment from the atmosphere, they are nevertheless gross feeders, and are bulky crops, and leave very little upon the soil to compensate for what they take from it. But great economy in feeding these crops may be effected by applying to them the long manure of the yard and stables, instead of summer yarding it, as many farmers are wont to do. These crops will feed upon what is otherwise lost in the yard, the gaseous matters. These afford exactly the food that the crops named want, and at the very time they want it.

14. Roots come next in the order of exhausting crops; but they compensate, in a measure, by the ameliorating influence they have upon the soil—in dividing, pulverizing and freeing it from weeds—by their roots and the culture they demand.

15. Green crops, that is, clover, buckwheat, rye, oats, &c. *ploughed under as food for plants,* are enriching crops, and powerful auxiliaries to the fold-yard, but they are too seldom resorted to for this purpose.

16. Depasturing with cattle, and particularly with sheep, enriches a soil. According to Van Thaer, it adds 20 per cent annually to the fertility of an ordinary soil, probably for a limited period. This results from the fact, that the crop is returned to the soil, in the droppings and urine of the animals which graze it.

17. Lime and clay are essential in a wheat soil. Indian corn delights in a rich, dry sand loam. Turnips excel on dry sandy soils. Rye is impatient of wet. Barley does best on a clay loam, as do beets, carrots and peas. Oats and potatoes find a congenial berth in cool moist grounds, though for the latter the surface stratum should be light, or mellow. Of the grasses, the tap-rooted, as clover, lucern, &c. require a deep soil, permeable to their long roots, and free from water; the fibrous-rooted, as the tall-oat, orchard, &c. thrive upon soils that are shallower; and the rough-stalked meadow, red-top, bent, and some of the festuca family are congenial to, and often natural in, moist or swampy grounds. The timothy, or meadow cat's-tail, the main dependence for winter forage, in the northern states, adapts its roots, it is said, to its location—being fibrous-rooted upon dry, and bulbous-rooted upon moist grounds—and therefore adapted to any situation.

18. The natural fertility of a farm cannot be kept up, or increased, where arable and mixed husbandry prevail, from the resources of the farm stock, without resort to an alternation, or change of crops. Although the diminution of fertility may be imperceptible, in some extraordinary cases—and although some soils seem naturally and peculiarly adapted to certain crops,—yet where the same crop is grown on one piece of ground in successive years, deterioration as certainly goes on as the sun shines by day. Whether, according to the modern theory of certain European philosophers, and men of high repute, the excrementitious matter thrown into the soil by a growing crop is poisonous to its species;—or whether, as we mantain, each species requires and exhausts, or partially exhausts, a specific food in the soil, suited to its particular wants,—we will not now stop to inquire; but it is a fact established by general experience, that an annual change of crops upon a field, while under tillage, tends very much to economise is fertility, and to increase the profits of the labor bestowed upon it. Hence,

19. It has been laid down as a sound rule in farming, that two white, or grain, or culmiferous crops, should not be made to succeed each other in the same field; but that each of these should be alternated with, or followed by, a green, a grass, a root or a leguminous crop

20. Where the soil of a farm will admit of it, a good course is to alternate, 1, roots or Indian corn, with long manure, upon the sod; 2, grain, with grass seeds; 3, grass for two years. The poorer the soil, the oftener should it be returned to grass, particularly to clover and pasture.

21. Geologists refer to three distinct formations as constituting the crust of the earth—the *primitive,* containing little or no lime, or organic remains: the *transition,* containing lime and organic remains;—and the *secondary,* abounding extensively in both of these elements of fertility. Their natural relative *fertility* is in the reverse order in which they are named, the secondary being best, and embracing most of the great basin of the Mississippi and the country drained by its tributary streams. We say nothing of alluvial formations, made by the ocean and streams. These partake of the character of the country from which they are brought, and are more or less fertile, according to the fertility of the districts from which their soil is derived, and the force of the currents by which the deposites have been made—a rapid current leaving only the coarser or heavier materials, while the lighter and richer matters do not subside until the current becomes slow and less agitated. A sluggish current, therefore, deposites the richest soil.

22. The three great formations which we have mentioned, possess, it is well known, characteristics different from each other. They grow, naturally, many plants peculiar to each, and they are adapted to different branches of husbandry, or to different farm crops. The primitive will not generally grow good wheat; but is suited to grass, oats, potatoes, &c. The transition is adapted to natural grasses, and to most of the arable crops, particularly to the cereal class; and the secondary to the cultivated grasses, to roots, and particularly to wheat.*

---

* An able writer in the Edinburgh Quarterly Journal of Agriculture, in reference to these formations, terms the primitive, which it seems comprises the most elevated lands in Scotland, the region of heath and coarse herbage; the transition, the natural region of the grasses; and the secondary the region of cultivated grasses, and particularly adapted to arable and alternate husbandry. He assigns to each a particular and distinct breed of cattle. To the first, or higher region, a thick haired, small hardy breed; to the second or middle region, those of larger size; and to the third, or lower region,

23. There are other circumstances, in regard to the location of a farm, which demand the consideration of the master, which refer to latitude and elevation. Plants have their natural zone, or climate, beyond which they do not grow, or thrive but imperfectly. There is a difference in every degree, or seventy miles, of latitude, upon tide-water, of five or six days, in the forwardness of natural vegetation in the spring, and nearly a like difference in the blighting indications of autumn. But what is of equal importance, but less generally regarded, is the difference in climate produced by altitude. Three hundred feet of elevation is considered equal to one degree of latitude, in its influence upon temperature. Hence it does not follow, that because a crop will thrive and ripen in a given latitude upon tide-water, it will thrive and ripen well in the same latitude at a higher elevation. On the contrary, to be better understood, we say, that, other things being alike, the climate on tide-water, in latitude 42°, is similar to that of a place three hundred feet elevated above tide-water in latitude 41°, or of a place nine hundred feet above tide-water in latitude 39°; so that the table land of Mexico, in latitude 16°, at an elevation of seven thousand and eight hundred feet above the ocean, should possess about the same mean temperature, and produce the same natural and artificial growth, as Kingston, upon the Hudson, though the extremes, both of heat and cold, are probably greater at the northern than they are at the southern point.* These data are assumed from recollection, and may not be precisely correct.

24. The means of preserving, and of augmenting, the fertility of the soil, are sufficiently indicated in the preceding suggestions. They consist mainly in manuring, draining, the admixture of earthy materials, and the alternation of crops.

25. Stable and fold-yard dung is most profitably applied in an unfermented, or partially fermented state, and to hoed and autumn-ripening crops. Fermentation diminishes the fertilizing properties of manure. If this fermentation takes place in the soil, the gases, the volatile portion which first escapes from the putrifying mass, are retained in the mould, and serve to feed the crop. If fermentation takes place in the yard, or upon the surface, the gases are wasted, and the dung undergoes further loss from the rains which ordinarily leach it. Long manure should be spread broadcast, and well buried by the plough.

26. Short manure, or that which has undergone fermentation, is most beneficial when harrowed in, upon arable lands, or spread upon the surface of grass grounds.

27. Old meadows may be kept in a productive state, in ordinary cases, by a triennial top-dressing with manure or compost; or may be renovated, and restored to a productive state, by the modes recommended in the first number of our present volume.

28. Composts are economical, when made to absorb fertilizing liquids which would otherwise be wasted—or to decompose inert vegetable matter, as peat earth, &c.

27. Lime, gypsum, marl and ashes are powerful auxiliaries, when applied to proper soils, or suitable crops. Observation and experience will be the best guides in their application. They should all be applied to the surface, or but superficially covered.

30. All vegetable and animal matters, constitute the food of plants, when they are rendered soluble, or capable of being dissolved in the water of the soil.

31. Bone dust, horn-shavings, poudrette, woollen rags, urine, and animal carbon, or burnt bones, are concentrated manures, and should be used sparingly and with great care, upon or near the surface of the soil. Pigeon and hen's dung partake much of the character of the preceding, and require precaution in their use. We think the best mode of applying the two first named, is to mix ashes with them, or long manure, just before they are put upon the soil, whereby they are brought speedily into a state of fermentation and decomposition.

32. The best guards against drought, are keeping the soil deep, rich, clean, and mellow on the surface.

33. The more cattle that are well kept upon a farm, the more manure; the more manure there is applied, the greater the product and the profit, and the greater the means of sustaining an increased stock of animals upon it. All of these advantages are increased when root crops are made to enter largely into the system of culture.

The Farmer's Garden.

The approaching is the proper season to lay out gardens, or to remodel old ones, preparatory to the operations of the coming spring. We shall therefore offer some remarks upon their formation and preparation; and intend hereafter to speak of the fruits and culinary vegetables most worthy of garden culture; and, subsequently, for the guidance of such as have a taste or desire to mingle the ornamental with the useful—to gratify the eye as well as the palate—we propose to give a list of shrubs, herbaceous plants and annuals which are in most esteem, and best adapted to our climate.

A kitchen garden, to which our observations will chiefly refer, should be near the dwelling, where it is not always practicable to *choose* the soil, the aspect, or the surface; these are in a great measure contingent upon the abiding residence. The best aspect is south, east, and the intermediate points, because it is the earliest; the best *soil*, is a rich deep loam, with a porous subsoil, that the roots of trees and plants may penetrate deep and broad, find plenty of sustenance, and be exempt from standing water. The best *surface* is one that is level or gently sloping, as such is least liable to be washed and impoverished by heavy rains.

Having selected a site, the next step is to enclose it with a substantial durable fence; for without this precaution the usefulness and beauty of the garden are at the mercy of every unruly boy, pig and cow of the farm and neighborhood. A hedge, with a fence to protect it on the exterior till sufficiently strong, is the handsomest, if not the best material. We don't make this recommendation in the expectation that it is likely to be followed by many, or perhaps any—for the idea is a prevalent one, and is sanctioned by the high authority of the Hon. James Garnet, that live fences are neither economical nor practicable in our climate—but because *we* think they can be made both cheap and efficient, when we become better acquainted with their management, and that they will ultimately be resorted to in many districts of our country where the materials for dead fences may become scarce and dear. Our reason for thinking they are practicable, results from our own experience: we have a strong substantial hedge of the three thorned locust growing, one of our native thorn, and one of privet. The two first are already a barrier to cattle, and they are all annually improving in strength and beauty. We have began to rear a fourth with plants of the buckthorn.

The *size* of the garden will depend upon the taste or convenience of the proprietor. It should not be less than the fourth of an acre, and may embrace, if garden fruit is to be cultivated, two acres. The plan which we submit with these remarks, and which we borrow from Cobbett's Treatise on Gardening, embraces about one acre.

In *preparing the ground*, three prominent objects should be kept in view: that the soil be made *dry*, that it be made *deep*, and that it be made *rich*. Underdrains, when necessary will effect the first; trenching, the second, and manure the third. A *wet* soil, or a soil liable to be wet during any part of the growing season, will not grow healthy vigorous plants. A *shallow* soil will not give sufficient pasture to the roots of trees, or a sufficient depth to the tap-rooted plants which must ever constitute a part of the products of the garden—and is soon affected by drought. A *poor* soil will hardly compensate for labor in garden products. But the soil being dry, and deep, and rich, the seeds well put in in season, and the crop well taken care of, no branch of rural labor makes a more profitable return than that which is bestowed upon a kitchen garden, especially where there is a contiguous market to take off what is not wanted for the family. The expenses of draining and trenching may be considered great and unnecessary; but they are not so in the long run. They are for time, and not for a season; and when once well done, need not be repeated. The fibrous roots of plants penetrate deep, where the soil is congenial, and extend to a great breadth. Cobbett traced roots of the common turnip four feet, and Tull proved that they extended to six feet. "It is well known," says Cobbett, "to all who have had experience on this subject, that of two plants of almost any kind that stand for the space of three months in topsoil of the same quality, one being on ground deeply moved [or trenched,] and the other on ground no deeper than usual, the former will exceed the latter one half in bulk. And as for trees, from the pear tree down to the currant bush, the difference is so great, that there is no room for comparison." A tolerable spadesman can easily trench four rods in an October or November day. This, at seventy-five cents a day, would bring the cost of trenching an acre, and of rendering it permanently useful, to $30—and the ploughings, harrowings, &c. would be superseded in the work of preparation.

The process of trenching is this: Begin at one end of the plat of ground, with the spade, a trench, all along, two feet wide, and two feet deep, unless an ungenial subsoil intervenes, in which case you may go some inches into this. "Throw the earth out on the side away from the garden that is to be; shovel out the bottom clean, and make the sides of the trench as nearly perpendicular as possible. Thus you have a clean open trench, running all along one end of your garden ground. You then take another piece, all along two feet wide, and put the earth that this new piece contains into the trench, taking off the top of the new, two feet wide, and turning that top down into the bottom of the trench, and then taking the remainder of the earth of the new two feet, and placing it on the top of the earth first turned into the bottom of the trench. Thus, when you have again shovelled out the bottom, and put it on the top of the whole that you have put into the trench, you have another clean trench two feet wide and two feet deep. You thus proceed till the whole of your garden ground be trenched;" filling up the last trench with the earth taken out of the first; "and then it will have been cleanly turned over to the depth of two feet." *Cobbett*, § 20. There is another strong inducement for trenching, where fruit trees are to be grown. Some gardens are found not to be congenial to the growth of certain fruits, as the pear, the plum, &c. This is often owing to the superficial stratum in which their roots are permitted to penetrate, often to stagnant water, reposing unobserved upon the subsoil, and often to deleterious materials in the subsoil itself. By draining, the water is conducted off; by trenching, the tilth is deepened, and the deleterious matters in the subsoil, within the natural range of the roots, brought under the improving influence of the atmosphere, and its injurious properties destroyed by that influence, and from becoming incorporated with the true soil. To those who know how to appreciate the value and luxury of a succession of choice garden fruit, an outlay of $30, or rather of $20—for the suitable preparation by the plough will cost $10—will think little of the expense, when put in competition with the advantages which are likely to result from trenching. And if a garden is to be trenched, it is better to do it before trees or shrubbery are planted in it, and the ground laid out, than after these operations have been wholly or partially performed.

We copy, as we before observed, from Cobbett, our plan of a garden, because we think it well suited to the wants and convenience of the American farmer; and that it is better to have trees and culinary vegetables in distinct compartments, than to mix them, to the prejudice of both, as is generally the practice. The plan embraces one acre. One-half, or one-quarter, of this space may be taken by those who are parsimonious of means, or who distrust the utility of a larger plat; and with trifling modifications which will suggest on reflection, the general outlines of the plan may yet be preserved.

---

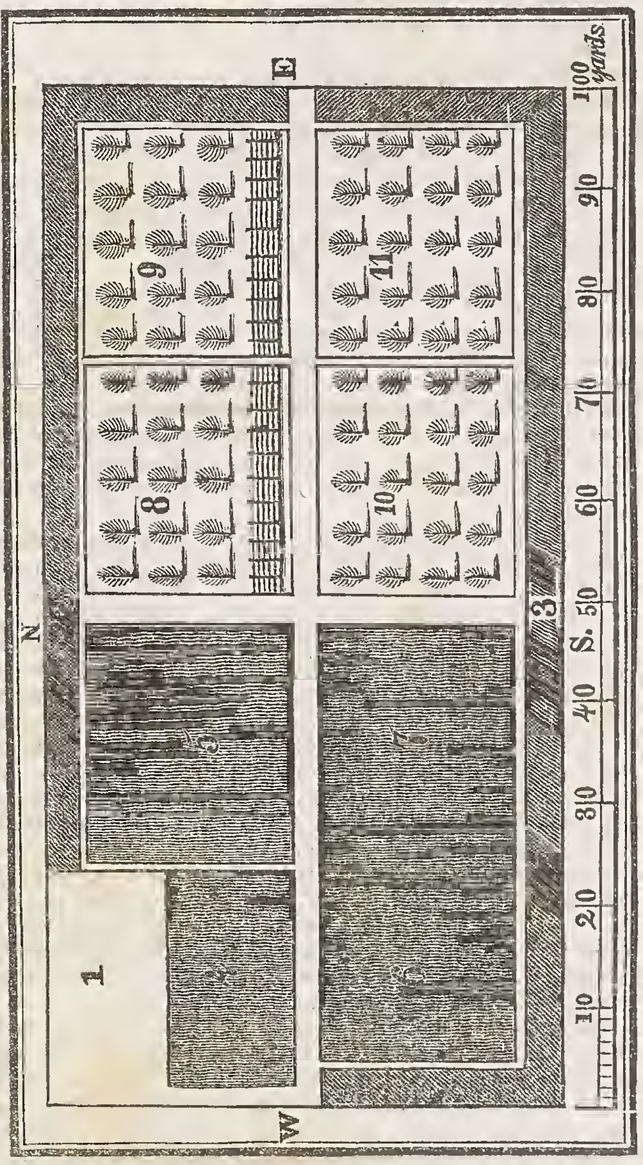
those that are more sensitive to cold, gross feeders, and that acquire the greatest weight. He goes on to show, from numerous examples, that these several breeds are the most profitable in the several districts assigned them; and that they are manifestly improved, in most cases, by a judicious cross with the improved short horns. There is much good sense in the writer's remarks; and although the descriptions of the three formations, as to elevation, does not fully apply in the United States, the facts we have copied afford useful suggestions to the American grazier.

* "All the western part of the intendancy of Vera Cruz," says Humboldt, in his New-Spain, "forms the declevity of the Cordilleras of Anahuac. In the space of a day the inhabitants descend from the regions of eternal snow, to the plains in the vicinity of the sea, where the most suffocating heat prevails. The admirable order with which different tribes of vegetables rise one above another, by strata as it were, is no where more perceptible than in ascending from the port of Vera Cruz to the table land of Perote. We see there the physiognomy of the country, the aspect of the sky, the form of plants, the figures of animals, the manners of the inhabitants, and the kind of cultivation followed by them, assume a different appearance at every step of our progress.

"As we ascend, nature appears gradually less animated, the beauty of the vegetable forms diminishes, the shoots become less succulent, and the flowers less coloured. The aspect of the Mexican oak quiets the alarms of travellers newly landed at Vera Cruz. Its presence demonstrates to him that he has left behind him the zone so justly dreaded by the people of the north, under which the yellow fever exercises its ravages in New Spain. This inferior limit of oaks warns the colonist who inhabits the central table-land how far he may descend towards the coast, without dread of the mortal disease of the *vomito*. Forests of liquid amber, near Xalapa, announce by the freshness of their verdure that this is the elevation at which the clouds, suspended over the ocean, come in contact with the basaltic summits of the Cordillera. A little higher, near la Bandarila, the nutritive fruit of the banana tree, comes no longer to maturity. In this foggy and cold region, therefore, want spurs on the Indian to labor, and excites his industry. At the height of San Miguel, pines begin to mingle with the oaks, which are found by the traveller as high as the elevated plains of Perote, where he beholds the delighful aspect of fields sown with wheat. Eight hundred metres higher, (two thousand and six hundred feet,) the coldness of the climate will no longer admit of the vegetation of oaks; and pines alone cover the rock, whose summits enter the zone of eternal snow. Thus in a few hours the naturalist, in this miraculous country, ascends the whole scale of vegetation, from the heliconia and the banana plant, whose glossy leaves swell out into extraordinary dimensions, to the stunted parachyma of the resinous trees."

PLAN OF A FARMER'S GARDEN.

[Fig. No. 46]



"The *laying-out* of a garden," says Cobbett, "consists of the division of it into several parts, and in the allotting of those several parts to the several purposes for which the garden is made. These parts consist of *walks, paths, plats, borders* and a *hot-bed ground.*"

The length of the garden, from east to west according to the above plan, is 100 yards; the breadth 50 yards. Cobbett's reasons for this form, an oblong square, are, "*first*, that we get by it a *long warm* border under the *north* fence for the raising of things early in the spring. *Second*, we get a *long* and *cool* border under the *south* fence, for *shading*, during the great heats, things to which a burning sun is injurious. *Third*, by this shape of the area of a garden, a large portion of the whole is sheltered, during winter and spring, from bleak winds." The following is Cobbett's explanation of the plan before us:

"The long walk, from east to west, is six feet wide, as is also the cross walk in the middle. All the paths are three feet wide. The borders, Nos. 2 and 3, are nine feet wide. The dimensions of the plats, Nos. 5, 7, 8, 9, 10 and 11, are (each) seventy feet from east to west, and fifty-six from north to south. Plat No. 6, is fifty-six by fifty. Plat No. 4, is sixty feet by thirty-six." And as to the mode of planting, he observes correctly, that all crops of large growth, as corn, peas, beans, onions, beets, &c. should be planted in rows to run north and south; while small crops are best planted in rows running east and west, across the beds.

It will be seen that a third part of the garden is appropriated to fruit trees, as the pear, plum, peach, cherry, &c.; that one-sixteenth is appropriated to hot-beds; and the remainder, embracing six hundred feet of early and late border, to culinary vegetables, medicinal and sweet herbs, small fruits, &c.

We would suggest that a portion of one of the borders be appropriated to a *garden nursery*; in which cuttings of the grape, currant, gooseberry, &c. and seedlings of fruit trees, may be planted, and budded or grafted, to replace those which decay. The currant will not do well in the same ground more than ten or a dozen years. The currant may be raised on a single stem, as a dwarf tree, if, previous to the cutting being inserted, all the eyes but two or three of the upper ones, are cut out with a knife.

An *asparagus bed* should be placed in an early border. It may be made from roots or seeds. The plants or seeds should be in rows across the bed twelve inches apart, the plants six inches in the rows. It will last many years if taken care of, pay well for the labor bestowed upon it, and yield one of the finest delicacies for the table.

We shall continue the subject, and proceed, in our next, to give some directions for filling the different compartments embraced in the above plan.

Prevention of Smut.

We extract the subjoined table from the Quarterly Journal for June, as particularly applicable and useful at this season. It gives the results of trials with various liquids, as steeps for seed wheat, made by Mr. Bevan, on a sandy soil in Bedfordshire. The columns in the table which are marked A. contain the result from the steeped grain which was sown; and those marked B. are the results from smutted samples.

LIQUIDS EMPLOYED.	No. of smutted ears in three sheaves.		Bushels of good wheat per acre.		Cwts. of straw per acre.	
	A.	B.	A.	B.	A.	B.
Solution of potash,......	1	81	21.6	13.6	36.6	29.1
——— muriate of potash,.	3	218	20.2	10.1	36.0	21.1
——— muriate of potash, (salt petre,)..	7	115	23.8	14.3	36.9	31.9
——— soda,...................	9	159	20.2	11.7	35.6	26.7
——— muriate of soda, (common salt,)	0	290	24.0	14.5	41.5	33.3
——— sulphate of soda, (glauber salt,).	12	241	21.6	12.3	38.5	27.8
——— muriate of ammonia, (sal ammo.)	1	150	19.8	17.6	35.4	30.2

——— lime, saturated, ...	0	2	21.9	12.4	38.7	25.9
——— nitric acid, (aqua-fortis,)	Seed	did not	vege	tate.		
——— muriatic acid, (spirit of salt,) ...	0	136	20.7	16.1	35.7	34.1
——— sulphuric acid, (oil of vitriol,)..	0	0	20.4	17.8	35.4	37.1
Dry, in its natural state,.............	0	323	20.3	14.7	35.7	31.1
Washed in common water,............	......	107	.....	18.3	....	35.8

It will be seen that the seed steeped in a pickle of common salt was free from smut, gave the greatest product in good grain, and the greatest weight of straw. This steep may be used by every farmer.

The article from which the above table is extracted was written by George W. Johnson. The writer examines the erroneous theories and opinions which have prevailed as to the origin or cause of smut in grain, and we think satisfactorily shows their fallacy. Mr. Johnson then proceeds to detail what he considers correct knowledge upon the subject, and quotes some of the most eminent naturalists in support of the opinion, that what passes by the different names of *smut, dust-brand and burnt corn* is a parasitical fungus, which preys not only upon the sap, but destroys the very organic structure of the grain and chaff upon which it fixes. Botanists generally distinguish this fungus by the name of *urido segetum.* Chemical analysis has shown it to consist, 1st. Of about one-third of its own weight of a green, butryaceous, fœtid and acrid *oil.* 2d. Nearly one-fourth of a vegeto-animal substance, perfectly similar to that which comes from *putrid gluten.* 3d. A *black coal*, one-fifth of its weight, similar to that which is found in all remnants of putrified organic compounds. 4th. Free *phosphoric acid*, amounting to scarcely more than .004 of the smut. 5th. Phosphates of ammonia, magnesia and lime, in the proportion of a few thousandths." "The contagion attacks especially the gluten, and precedes, indeed prevents, the formation of starch." It has also been shown, by Duhamel, Kirby and others, that the disease exists in the affected plant, before the development of the head; that it is propagated by minute seeds, which attach to the kernel, and which are so light as to float buoyantly in a damp atmosphere; that the vitality of these seeds is not destroyed by frost; but that they will contaminate seed grain, with which they come in contact, after being long in the soil. In early spring, when the plants were but a few inches high, upon carefully opening the hose or blade which covers the ear, M. Duhamel found this embryo already black and distempered. After quoting the results of many experiments besides those in the above table, made by Mr. Bevan, Mr. Johnson adds—

"The conclusion from these and many other accordant experiments is, that washing the seed is effective in preventing the communication of the disease to the crop to which it gives birth. If the washing was frequently repeated, or the cleansing made complete, by passing a continued stream through the wheat for some hours, it is probable that simple water might be employed for this purpose as effectually as any saline solution. But as this would require more labor than is desirable, and as the salts, &c. employed are beneficial in other ways, by protecting the seed from vermin, and ministering to the future vigor of the plants, steeps are generally and very properly adopted."

If lime be adopted, it is recommended to prepare it by mixing "one pound of fresh lime with three gallons of boiling water, allowing these to stand for two hours, and the clear liquor then to be poured off and immediately used. In this liquor the wheat should be soaked for twelve hours, stirred twice or thrice during the time, and then mixed upon a floor, with the powder made by pouring three gallons [pints?] of boiling water upon five pounds of lime."

Mr. Johnson has had no experience with lime himself; but he has witnessed many experiments with stale urine and a solution of common salt. He thinks the latter the most agreeable; and although both were completely effective, without exception, he has used the salt, as being most cleanly as well as convenient. His mode is, to wash the seed with pure water, to skim off the floating light grains, and then to soak it twelve hours in a pickle made with common salt, strong enough to float a hen's egg. Mr. Johnson is satisfied, from experiments he made, and which he details, that the soil is one source of infection, and that salt is an antidote to this infection; and he thinks the truth of these opinions is confirmed by the fact, "that fields in the vicinity of the sea are rarely injured, and never extensively, by the ravages of the smut."

Green's Straw Cutter.

Our ingenious countryman, Mr. Green, has received a high compliment, in the encomium which has been passed upon his machine by the Highland Agricultural Society of Scotland. A description of this machine was sent from Canada to the secretary, by Mr. Ferguson, who pronounced it "the easiest and the most effective cutter he ever met with—a real first rate machine." The communication was laid before the committee on machinery, who, after making a machine according to the description, and sufficiently testing it, reported that they found it "to bear out all that was reported of it by Mr. Ferguson;" that "it is now ascertained, that it will cut *three times more* than the best of the common sort, and with *less force;*" and that "one person driving the machine will cut with ease five hundred weight of hay or straw in an hour." This is a high, but deserving commendation. The notice, with a cut of this machine, is published in the society's papers for June.

Suggestions to the Wool Grower.

Hitherto the attention of the farmers has been principally directed to the rearing of sheep for the profit of the fleece, or of the carcass separately, without reference to the advantages to be derived from both conjointly. Hence the Saxon, Merino and New-Leicester breeds have been principally sought for, the two first on account of their fine wool, and the latter on account of the great weight of carcass. The great increase in the number of fine woolled sheep, and the serious depression for some time in the wool market, render it worth the consideration of the sheep master, whether he cannot vary the character of his flock to advantage.

The South Down sheep of Britain have the reputation of making the best mutton of any breed; and this mutton sells for a penny a pound more in the London market than any other. We have ate of this mutton several times, and recently, and think it deserves all the commendation bestowed upon it. The sheep are hardy, and are peculiarly adapted to light upland soils. They take on fat quick, and come to early maturity. This breed has been recently improved by a cross with the improved Cotswold, with great advantage to the fleece, without seeming prejudice to the mutton. A Mr. Troynam states in the July number of the Farmers' Magazine, that he obtained from 300 ewes of this cross, while suckling their lambs, an average of five pounds of wool each, and from 110 yearlings, an average of seven pounds two ounces each. The wool sold at 42s. per tod of 28lbs. which is equal to 32 cents per lb. or $1.60 for the ewes, and $2.24 for the yearling fleece.

Harvesting Corn.

As the Indian corn harvest comes in this month, we would suggest to those who have not adopted the practice, to cut the crop at the ground, and immediately to deposite it in stooks, as a means of lessening the harvest labor, of securing the crop from the injurious effects of early frost, and of materially enhancing its value, over the old mode of topping. The crop may be cut as soon as the grain has become glazed. By our experiments, made with great care, the details of which will be found in our last November number, we gain six bushels an acre, in heavy corn, by cutting up the crop, over what we obtain by topping it, and make a still greater gain in the forage.

A Steam Plough,

Is now being constructed in New-Jersey, designed for operating on the western prairies. An intelligent gentleman who has examined it, has so much confidence in its success, that he tells us he has ordered one for his own use, in the valley of the Wabash.

The Crops—(Private Correspondence.)

After ordering a quantity of Rohan potatoes and Dutton corn to be forwarded to him the coming fall, our Baltimore correspondent, G. B. Smith, adds: "I would remark, that I place great value on the fact of getting these articles from you direct, for our farmers have been so greatly hoaxed or cheated by seedsmen, that they have little confidence in them. I could not have sold the spring wheat (Italian) had Mr. B. not been able to have brought a letter from you. All I sold has turned out well. The extreme heat has caused much of it to *shrink*, but it has all made a good crop. What little Siberian was sold here has not done well at all; and a great deal that I knew was of a doubtful character, and refused to have any thing to do with, has, as I expected, resulted very badly. At present the prospect of the Dutton corn is favorable."

Mulberry Farm, N. J. July 29.—"Our harvest is over, and we have but a poor crop,—I mean a light one. Rye is meagre enough. Some of our best farmers say they have not half a crop. As a general remark, I believe we shall not gather more than ten bushels to the acre, this section of country over. This region is one of the best; indeed more rye is raised upon an equal number of farms than on any other in the state. The grass crops are proportionably light. Oats are not half a crop. Corn is so injured by drought, that one and all agree there cannot now, if rain should come within a few days, be more than half a crop. There has been no rain for six weeks past, and vegetation generally is suffering beyond recovery. Pasture there is none. Potatoes are scarce—buckwheat destroyed by grasshoppers. Truly the farmer's prospect is discouraging and dark enough. J. N. B."

Knoxville, Te.—"The small grain harvest was never better in East Tennessee. The crop from the golden chaff, alias Missouri wheat, is unusually large. It is decidedly the favorite of our farmers. It was from its first introduction into this climate excellent—but the acclimating process has improved it essentially. We have been experimenting with the Siberian wheat, but as it is not yet matured, I cannot say how it suits our soil and latitude. *J. G. M. Ramsey.*"

Braintree, Mass.—"Wheat has failed with me, (the Siberian spring.) It has rusted; the kernel has not filled. The land was limed, and the produce of straw is estimated at two and a half tons per acre —so we are here at a loss for some crop to seed down with in June, from our lands being springy, as our farmers reject oats and barley. Of hay our yield has been abundant, I should judge a quarter more than the last season, and it has been got in well. Corn promises well. Potatoes in many places lack rain. Fruits not so abundant as the blossoms indicated, though the growth of wood has been great. On the whole, the countryman has this year more than usual to be grateful for. *B. V. French.*"

The rust is a sufficient cause of the shrinkage of the wheat, and the crop should be cut as soon as it appears. It seems to us, besides, that the soil of East Massachusetts lacks something besides lime, to fit it for the wheat crop, viz. animal matter, an essential element of the gluten of wheat. Barley and oats are good crops on soils adapted to their growth; and we suspect, by the greater amount of their product, on such soils, would make a better return than wheat does there. We advise our correspondent to try again. First to underdrain his wet grounds, which will enable him to sow early; and if he is anxious for the wheat bounty, let him apply some concentrated manure, containing animal matter, as bone dust, horn shavings, poudrette, animal carbon, urine, fish or slaughter-house manure. These article are all *comeatable* in the vicinity of Boston.

Greenwich, N. J. August 9th, 1838.—"The wheat crop with us was quite promising, but suffered from the rust, and many of our farmers have their crops injured by the smut. The corn crop never looked more promising than at the commencement of last month, but we have had no rain for more than four weeks, and much of it is now entirely dry; but I suppose that rain in a few days would probably make half a crop. Some buckwheat was sown before the ground became too dry for vegetation—some have been waiting for rain, and have not sown; and some that was sown since the ground was dry does not vegetate. Respectfully. *Benj. Sheppard.*"

From the various notices in the newspapers, and from information derived from travellers, it seems certain, that the early harvest, embracing winter grain and hay, has been unsually abundant throughout our country. Yet we regret to learn, that the drought of July has been severe and disastrous to the late crops, all along our Atlantic border, from Virginia to Massachusetts.

In Virginia, it is stated from Norfolk and Winchester, that the corn crop has been greatly injured, and upon light soils nearly destroyed.

In Maryland, the injury is still greater; in Frederick and Washington, two of the best agricultural counties, "many farmers have cut down their corn stalks, with the intention of putting wheat in the fields. In many fields the yield will not be half a barrel ($2\frac{1}{2}$ bushels) the acre. The clover and pasture fields have also suffered dreadfully, and upon many farms they have had to resort to their hay to sustain their stock."

In Pennsylvania, the injury has also been very serious. It is stated from Harrisburgh, that "the corn and potato crops are considered as gone past recovery. The farmers are turning their cattle into their corn fields, and cutting their stalks up for fodder." Fruit, also, has been much injured.

In New-Jersey, the south part of New-York, Connecticut, Rhode-Island and Massachusetts, the drought has also been severe. It has been less so in this vicinity; though here the corn, potatoes, and late sown wheat and oats will be sensibly diminished in product. The heavy rains which fell here on the 5th and 6th August, completely saturated the soil, and revived and gladdened animated nature. In the northern and some portion of the western parts of our state, there has been no want of rain.

On Earthing Potatoes.

The general practice has been, and now is, to earth the potato crop, by making conical hills or ridges.—But, within a few years, the propriety of this mode of culture has been doubted, as tending to curtail the pasture of the plant, and to expose it to greater injury from drought; and several, who have experimented in the matter, have come to the conclusion, that the crop is most productive when but partially, or not at all earthed. A French Journal gives the following as the result of one experiment made by M. de Dombale:—Eight rows were horse-hoed; some little time after they were earthed up, and when five inches high they were again earthed up. Other eight rows in the same place, and under exactly the same circumstances, were *only horse-hoed*, at the same time with the others, but received no earthing up or subsequent culture. The product of the earthed up potatoes was 1,222 lbs; of the others 1,408 lbs. and in a very fertile spot, the difference was one-third in favor of the latter.

Effect of Steam Power.

The effect of steam navigation in enlarging the commerce in eggs, has been wonderful. The importation of eggs from Ireland, during the last year, to Liverpool and Bristol alone, amounted in value to $450,000. The importations into England from France, were probably much greater. The egg commerce of our country has also been greatly increased, by the facility of transporting them to our large towns by means of steam. Equal facilities have been afforded, by steam navigation, for the transportation of beef cattle. Thousands of fat animals are now annually taken down the Hudson, on board of boats towed by steam. Rail-roads are also now being employed for the transportation of fat animals, and promise important advantages, not only in diminishing the expense of marketing, but in preventing the waste of flesh incident to driving a distance.

Horticultural Society of the Valley of the Hudson.

This society was organized in May last. We have not hitherto noticed any of its proceedings, from the hope, that ere this, we should have been able to publish them entire, with a notice of the first exhibition. The proceedings and notice came to us first in a printed form after the present number of our paper was prepared for press. We are obliged, therefore, to be content with giving them a brief notice for the present, reserving to a future opportunity a more detailed statement.

The plan of this association originated with a few individuals, who were desirous of profiting themselves and the public, by the improvement of horticulture and rural embellishment, in the valley of the Hudson—by introducing and disseminating among us, all the choice garden and orchard fruits, culinary vegetables and ornamental plants, that are congenial to our soil and climate, and suited to our wants and comforts. A circular, inviting a meeting at New-York on the 30th May, for the purpose of organizing an association, was printed, with the following respectable names attached to it, viz: Morgan Lewis, James G. King, J. Buel, Stephen Van Rensselaer, Ed. P. Livingston, John W. Knevels, Theodore Allen, J. R. Stuyvesant, John Torrey, Alex. Walsh, Geo. C. Thorburn, Ph. S. Van Rensselaer, James Wilson, A. J. Downing, Wm. Thorburn, J. A. Thompson, Jas. A. Hamilton and Freeborn Garretson. From an untoward series of disappointments, these circulars had but a partial circulation, and did not arrive in N. York for distribution till the day before the time appointed for the meeting.

A meeting of respectable gentlemen, from different counties on the Hudson, did, however, take place at the rooms of the Lyceum of Natural History, in New-York, on the 30th May—a constitution was adopted, officers were chosen, and preliminary steps were taken to have a semi-annual exhibition of horticultural productions, together with a suitable address, at the rooms of the Lyceum, No. 563 Broadway, this fall. The time of the exhibition has now been fixed for the 27th of the present month of September.

The *objects* of the society, as set forth in the constitution, are—"the promotion of horticulture, and the taste for rural improvement in general—by comparative exhibitions, at which medals and premiums shall be awarded—by procuring and disseminating choice fruits and plants—by experiments in culture throughout different sections of the territory embraced—by lectures and essays on various subjects connected with the science and practice of horticulture—and in such other methods as shall be deemed advantageous by the association." The constitution also declares, that there shall be semi-annual exhibitions—first, the summer meeting, for the smaller fruits and earlier flowers, to be held in June, at Albany, Poughkeepsie and Newburgh, alternately; and second, the autumnal meeting, for the larger variety of hardy fruits, and late floral and vegetable productions, to be held in September or October, in the city of New-York. The terms of admission to members, are an initiating fee of *Five Dollars*—no annual contributions are exacted.

The following officers were elected for the ensuing year:—J. Buel, of Albany, President; A. J. Downing, of Orange, Corresponding Secretary; N. G. Carnes, of New-York, Recording Secretary; G. C. Thorburn, of New-York, Treasurer; Ph. S. Van Rensselaer of Albany, Ed. P. Livingston of Columbia, E. Holbrook of Dutchess, N. Becar of Kings, Alex'r Walsh of Rensselaer, John Torrey of New-York, C. Ludlow of Orange, R. Arden of Putnam, J. E. Dickey of Queens, Eleazer Lord of Rockland, Samuel Young of Saratoga, A. B. Hasbrouck of Ulster, James A. Hamilton of Westchester, and William Emerson of Richmond, Vice-Presidents. *Executive Committee:* Theodore Allen, J. R. Stuyvesant and J. W. Knevels, of Dutchesss; Henry Robinson, J. F. Betts and C. Downing, of Orange; J. M'Donald M'Intyre, William Thorburn and James Wilson, of Albany; and John J. Palmer, James Pennell, (M. D.) J. A. Perry, James R. Hamilton, John Groshon, and William R. Rushton, of New-York.

Gentlemen throuhout the valley of the Hudson, and elsewhere, are requested to bring to the exhibition, on the 27th September, such horticultural and agricultural products as may serve to make up a complete comparative exhibition of the various fruits, flowers and vegetables, produced upon our diversified soils.

The Horticultural and Pomological Societies of Europe, have effected important benefits to mankind, by their labors in producing new varieties of fruits, flowers and enculents, and in collecting, and disseminating the choicer varieties. We are indebted to their labors, at this day, for many new and valuable kinds, which otherwise would probably have remained unknown to us. Nor do we lack evidence, at home, of the utility of these associations: the societies at Boston, Philadelphia, Baltimore, Washington, and in the western part of our state, have done, and are doing, much, to multiply the sources of human enjoyment, and to promote a laudable taste for rural embellishment and social enjoyments. When we consider the science, the wealth, the taste, and the professional talent, that may be found in the valley of the Hudson—the liberality and enterprise of its population—the susceptibility of our valley for high and picturesque improvement—and the advantages which may be made to flow from the labors of the society,—we cannot hesitate in expressing a conviction, that the project will be promptly and generously sustained and supported by our enlightened citizens.

Application for membership may be made to the officers named above, who will furnish the printed proceedings, embracing the constitution, and a diploma, under the seal of the corporation.

Great Sale of Short-Horned Cattle.

The Short-Horned stock of C. S. Clarkson, of Cincinnati, full and part blooded, was lately sold at auction. It comprised 91 animals, and sold for the gross amount of $27,802—averaging $305 each. One of the cows with a calf, sold for $1,075; a cow, 12 years old, sold for $1,000; a yearling heifer at $700; a two year old heifer at $875; a three year old bull $1,450; and a bull calf, 9 months old, for $1,000!! When will our farmers learn, from these extraordinary prices, the difference between superior and ordinary cattle? When they appreciate justly their true interests. By the way: we think the Short-Horn fever has attained a crisis in Ohio and Kentucky, and that prices must hereafter retrograde, rather than advance. We remember that in 1815, or thereabouts, some Merino bucks sold for $1,500, and that a few years afterwards they sold at $50, and even at $15. To use a common sense proverb—"there should be reason in all things."

A Flora of North America,

By Prof. John Torrey and Asa Gray, is now being published by Messrs. Carville, New-York, Carey & Lee, Philadelphia, and Little, Brown & Co. Boston. It is to be comprised in three closely printed vols. of 550 pages each, and is to embrace all the indigenous and naturalized plants growing north of Mexico, including Nuttall's collection from the Rocky Mountains. The first volume is to comprise the exogenous polypetalous plants, and to be published in three numbers, or parts, of 184 pages each—price $1.50 for each part.

Flax Culture.

We have been presented with two specimens of flax fibre, one in a greenish unrotted state, and the other, termed short-staple, prepared by a new process, white, soft and delicate, fitted for the finest fabrics. This short staple may be carded, spun and wove, by machinery, like cotton. Three tons of stem will make one ton of unprepared lint—seven tons of stem will make one ton of short-staple lint. This new discovery in the process of preparing the lint, will give encouragement for an extended culture of flax, particularly in districts where it is now raised for the seed only, as in Seneca county—as the stems will be worth $12 per ton to the grower, exclusive of the seed, as soon as they are thrashed. If the anticipations which have been indulged in, of the value and importance of this discovery, should be realized, flax is likely ere long to become one of the great staples of our soil.

Insects—Genus Curculio—Weevil.

A series of papers is being published in the Edinburgh Quarterly Journal of Agriculture, "On insects most injurious to vegetables and animals, and the means best calculated to counteract their ravages," by James Duncan. Of the genus Curculio, Mr. Duncan informs us, no less than five hundred different species have been described as inhabiting Britain.—"Both in the larvæ and perfect state, they feed exclusively on vegetable substances." Since the time of Linnæus, naturalists have subdivided them into a multitude of genera. They are found to be very formidable enemies, both to the farmer and gardener. Some, in their larvæ state, prey upon the roots of plants; some upon the foliage; some upon the blossoms; some upon fruit; and some upon ripened seeds, as the weevil upon the contents of the granary. This last kind, particularly prejudicial to the farmer, is denominated

"*Calandra granaria.*—The extensive devastations of this, the *grain-weevil*, as it is called *par excellence*, have obtained for it a kind of bad eminence among its compeers, and caused its habits to be investigated with considerable attention. Several circumstantial accounts of it have accordingly been published; but we cannot, for that reason, omit to include a resumé of its history in a general notice of the insects destructive to vegetable produce, more especially since the best of these accounts are in a foreign language, and in works not readily accessible to the general reader. It is the only species of the genus *Calandra* that can properly be considered a native of this country, and presents the following generic peculiarities:—Antennæ scarcely longer than the head and rostrum, inserted near the base of the latter, nine-jointed,—the elongated radical joint, when bent backwards, reaching to the thorax,—six following short,—the remainder forming a narrow, somewhat ovate club, the apex of which is spongy; rostrum rather long; thorax elongate, a little narrowed in front; elytra scarcely longer than the thorax, and not quite covering the abdomen; legs rather short. The species in question is nearly two lines in length; of a brown or pitchy colour when mature, but pale on first emerging from the pupa; the thorax is nearly as long as the elytra, rather depressed above, and covered with large oblong punctures; elytra scarcely so wide as the thorax at their base, the surface marked with deep lines faintly punctured in the bottom; under side of the body also punctured; legs rusty red.

"This insect frequents granaries and other repositories of corn, where the female buries herself in the heaps, and deposites her eggs in the grain. For this purpose she makes a small hole with her rostrum in the skin of the grain in an oblique direction, and, after having placed an egg in it, closes the aperture by means of a glutinous matter. Never more than one egg is consigned to a single grain, as the whole of the substance of the interior is insufficient for the support of no more than one larva. The latter is hatched in a longer or shorter time, according to the temperature, but usually after a few days. It is a small vermiform creature, of a white colour, and about a line in length, composed of nine segments, the body soft, but the head of a harder consistency, in order to afford sufficient support to a pair of strong jaws, which are the only external organs it has either space or apparent inclination to employ. With these it erodes the farinaceous substance of the grain, continually enlarging its dwelling as it continues to increase in size; and by the time that the whole of the interior is scooped out, it is prepared to assume a different form when food is no longer necessary. The pupa into which it now changes is also white, somewhat transparent, and lies like the kernel of a nut within its shell, the latter being formed by the exterior envelop of the grain. When the perfect insect is matured, it makes its escape by gnawing a hole in the walls of its tenement.

"The period when these changes take place, and the duration of each successive state, are greatly influenced by the temperature. In the south of France, for example, the female commences laying in the month of April, and the insects continue to propagate till September. In this country they increase rapidly only during the warmer months of summer. As might naturally be expected in such circumstances, the geographical distribution of the *Calandræ* is likewise dependent on temperature; they occur in profusion in the south of France, and similar latitudes in Europe; are likewise too abundant in London and the southern districts of England, but gradually become less plentiful as we advance northward. We believe that they seldom occasion any serious damage in Scotland. On an average, it may be stated, that from forty to forty-five days elapse from the union of the sexes till the evolution of the perfect beetle, the greatest proportion of which is spent in the larva state. From the number of eggs laid by a single female, it has been calculated that her descendants may amount, in a single season, to 23,600 individuals; a degree of fecundity which may enable us to judge of the evil they are calculated to produce when their numbers, in the first instance, are considerable.

"Although the larva is of course the principal cause of this injury, the perfect insects take likewise a direct share in it, by gnawing the grains. It has, indeed, been denied by some observers, that they ever do this, except when making an opening for the admission of the egg; but it is utterly improbable that they should, for such a length of time, frequent places where they can have access to no other kind of food, without using the grain as such. In this condition, however, probably very little food suffices, and the injury done consists rather in the frequent breaking of the skin of the grain, than in the actual quantity of its substance consumed.

"The grain into which this insidious foe has been so expertly introduced, presents no external appearance of being unsound, but when immersed in water, it floats on the surface, a circumstance which intimates that the farina has been destroyed. When this is the case, the infected particles should be removed, if possible from the heap, and the enclosed beetles killed. But in an extensive granary, this is obviously no easy task, and the loss arising from the insects will not in many instances, greatly exceed the trouble and expense incurred by any means of separation that has yet been employed. If the damaged grain, however, be so much lighter as the above-mentioned circumstance seems to indicate, it appears probable that if the whole were passed through a winnowing machine, it would be thrown out in the same manner as the chaff and light corn are in an ordinary case. If this operation were found to answer the purpose, it could be more easily carried into effect than any other plan that has been recommended. That of exposing the corn to heat, is liable to this objection, that before the eggs or larva could be destroyed, the temperature would require to be so high that it would dry the corn too much, and even calcine it.

"The principal object ought to be the destruction of the beetles before they have had time to lay their eggs; after that operation is accomplished, they spedily die of their own accord. Of the various schemes that have been proposed for this purpose, the following is the most approved. When the individuals have passed the winter in a torpid state, are beginning to recover their activity, and to move about among the grain, a small heap, composed of that kind of corn to which they are most partial (which is said to be barley,) should be placed at a small distance from the principal store. The latter should then be turned over, and tossed about as much as possible, at intervals, that the weevils may be fairly disturbed and put in motion. Naturally very fond of quiet, and anxious to escape from such unceremonius treatment, they take refuge in the undisturbed heap placed as a decoy. When collected there in numbers, they are speedily incapacitated for further mischief by having boiling water poured over them in such quantities as completely to saturate the heap. Such individuals as escape to the walls or elsewhere, may be swept together by a broom, and easily disposed of.—The corn of the decoy-heap may afterwards be separated from the dead insects by sifting. Even though this plan may appear not to promise much in the recital, it is affirmed that, in practice, it has been attended with highly favourable results.

"As these creatures do not propagate except at a pretty high temperature, attempts have been made to check their increase by keeping that below the requisite degree. The only means employed for this purpose is free ventilation; but this must necessarily prove inefficient; for it is obviously impossible, in the summer months, thereby to effect such a reduction as is at all likely to influence their economy. More might be expected from mixing the corn with quick lime, sulphur, or some other substance which seems fitted to disgust them; but this could only be done with grain designed to be used as seed; for the taint they are likely to communicate, render such applications inexpedient when it is to be employed for other purposes."

It is our intention hereafter to make further extracts from the interesting numbers of Mr. Duncan.

Suggestions, &c. in Husbandry.

[*Abstracted from foreign publications.*]

BONE MANURE.

C. W. Johnston, who has recently published a work of repute on liquid manures, in an article on bone dust, in the Farmers' Magazine, condemns the practice of mixing plaster with it, for turnips, as the latter, he says, is not a fertilizer to the turnip crop. The price of bone dust in England, is from £4 10*s* to £5 5*s* per ton (20 to 24 dollars.) Thousands of acres have been brought into a productive state, by the use only of this fertilizing material. The introduction of the use of bone dust into the United States is very recent. But two or three crushing mills have yet been erected; and the demand for agriculture is likely to keep pace with the supply. There are three advantages arising from the use of this and other concentrated manures, as poudrette, horn shavings and animal carbon, &c.: they are portable—enough for an acre of land can be carried at a single load—they act speedily—their effects being immediate—and they promote clean husbandry, being free from all seeds that annoy the crop, and of course save labor in weeding, where they are applied. Diminutive in quantity as they may seem, they have nevertheless become, in Europe, auxiliaries to the cattle yard, and are becoming so with us, in the improvement of the soil. Our practice is to mix the horn shavings and crushed bones with our recent yard dung, when on the eve of applying it, at the rate of a bushel of the one to a load of the other. This induces fermentation, and we think the effect is highly beneficial.

THE TURNIP FLEA.

We find in our foreign agricultural journals—many communications on the subject of the turnip flea (*Haltica rumosum*). One of these, from Henry Le Keux, is particularly descriptive of the habits of the insect, and details a great number of experiments which the writer had gone into to prevent its ravages. The result of his long continued experiments seems to be, that the best and most efficient mode of preventing their depredations upon the ruta baga, is, as our Dutchess correspondent recommends in regard to the grub—to feed them with a more attractive food, than the plants which we would preserve. And M. Le Keux, therefore, sows the seed of the common white and stone turnip with his ruta baga. "I have *invariably* found," he says, "where this has been done, that the former are first attacked, and sometimes, and indeed generally, destroyed, before the latter have been touched, which by that time have grown to such a size as not to be injured by them; and in seasons when the fly has not been very numerous, the Swede has not had a single puncture upon it, while every leaf of the white stone turnip, by the side of it, has been pierced full of holes." M. Le K. detected the larvæ of this insect *in* the leaf, between the epidermis and lower surface.

MANGEL WURZEL.

Mr. Hillyard, an extensive cultivator of this root, gives the following concise observations in regard to the culture, use and preservation of this root, in the Farmers' Magazine.

"Those who have not a depth of mould free from couch, and a good supply of manure, had better not attempt the cultivation of the mangel. It will grow on soils where Swedes will not grow. For lambing ewes in the spring, it is invaluable. Mangel improves by keeping. It should be drilled or dibbled about one inch deep. *Soak the seed till it sprouts*—[an excellent precaution.] I dibble in single seeds 3½ inches apart, in a hole made by a boy pressing down, by a handle about four feet long, a piece of wood sixteen inches long,* and about four broad, with three pegs in, seven inches asunder, to make 3 holes one inch deep, one seed put in each hole, (two if the seed does not appear good) and rake the holes in. When taken up the latter end of October, [this should be done as soon as the tops cease to grow, or the under leaves turn yellow,] strip off every leaf, and throw into furrows two rows, which pull up by hand, the other with double mould board plough, with shell board off. Dig pits two or three feet deep, and twelve broad; in these the roots are stacked, and ridged up to the height of ten or twelve feet from the surface of the earth. Faggots should be set upright about every two yards in the centre of the pit, [before the roots are put in] and continued to the roof, all along which, faggots should lie. By this contrivance heat is carried off, and rotting prevented. Cover up with dry straw or haulm, then cover with mould, allowing a little time for the heat to escape, before completely covering the stock for winter [or spring] store."

An "Essex Farmer" feeds mangel to his horses, and finds it an excellent substitute for hay. He feeds his horses with it all through winter, at the rate of half a bushel per head, mixed with chaff, and one bushel and a half of corn oats per week to each. His horses are thus kept in good working order, and he says he saves 30 per cent, by thus substituting the mangel for hay.

FEEDING CATTLE—MANURES.

It is customary at the cattle shows in Britain, for the successful competitors for premiums in particular, on receiving their award, to address the company present. We find in these addresses many suggestions of practical use, and from practical farmers. At the Suffolk show last December, on the chairman suggesting, that as it was the expectation as well as wish, to blend instruction with festivity, he hoped that any gentleman present who could afford information with respect to farming operations, would favor the company with it. Mr. Shillitto, one of the successful competitors for good stock, rose, and after some preliminary remarks, proceeded as follows.

"The first step of importance, in his opinion, was to obtain a good *sort* of animal, an animal that would car-

---

*We have used a dibble of this kind. It may be likened to an inverted ⊥; the perpendicular being the handle, and the pegs being inserted in the lower side of the cross or horizontal piece. When the dibble is placed down at the right gauge, which may be readily done by placing the last peg of the dibble in the last hole made, the boy presses with his foot, if necessary, upon the horizontal piece, so as to make the holes sufficiently deep. The pegs may be 3½, instead of 7 inches apart, and thus abridge the labor. In well prepared ground a boy may dibble at a good pace.—*C. Cult.*

ry quality as well as quantity—meat as well as size. The next step was its proper feeding, and to this last point he had paid much attention. One thing to which special notice should be paid, was the quantity of food given to animals. It was a maxim with some breeders to give them large quantities—to gorge them. This, however, was decidedly wrong. On the contrary, be careful not to furnish them with too much, or, in plain terms, more than the animal could thrive as well as fat upon. Again, it was necessary the animal should have a variety of food; for he had seen that, if breeders went on with feeding with one kind of food, the stomach got cloyed. As soon as he saw that taking place in his own beasts, he immediately changed the food. Whenever he walked through his yard, and found an animal not taking sustenance in proper quantities, he had him instantly removed from the rest, until his appetite was restored." "Another matter to which the attention of the breeder should be directed, was the quantity of water given to a beast. Every animal should be allowed to drink two or three times in a day, if it had not water always at command."

The brute, like the man, delights in variety. One kind of food soon cloys the appetite, and excess deranges the digestive organs. *We* want drink, and *salt*, with every meal; and why not the brute? On the subject of manures, Mr. Shillito remarked.

"The modern agriculturist, he thought, did not pay sufficient attention to the manures made in the fold-yard. Sometimes he had been asked how his fatting animals paid him for the trouble of producing them. This, however, could not be answered by a mere reference to the sum he obtained for them by sale—but there was a variety of circumstances to be considered before he could answer it properly. For instance—the quantity of manure obtained from them was one—not wet straw, but good manure. There was another thing which required attention—when the manure was carred from the fold-yards into the fields, it was suffered to lie in a large heap for a long time—so long, indeed, that before it was spread upon the land its qualities had perished. He was aware that it required a certain time for fermentation to take place, but it was frequently left till such fermentation had passed off. It was his practice, as soon as the heaps were raised on the field, to throw a quantity of mould upon it, and thus prevent evaporation taking place too rapidly. Proper attention ought also be paid to draining the fold-yard. The produce saved was now in ten out of twelve instances lost. It would be advisable when the yard had a fall, to establish conveniences for catching it, and then convey it to the lands. In France and the Netherlands they were extremely careful in preserving this liquid manure, and the peasants might be seen conveying it out to the fields, and giving each plant a proper proportion."

BATH AND WEST OF ENGLAND AGRICULTURAL SOCIETY.

At the meeting held in December, Dr. Wilkinson communicated the result of a useful invention of Mr. Perkins, for the warming of houses, by which any degree of heat might be obtained, and a room once warmed might be kept at one equal temperature. The expense on the whole would be less than the present mode of warming rooms.

Dr. Wilkinson proposed a premium of £20 for the best essay on the theory of De Candolle and Macaire, that the excrementitious matter of plants is poisonous to similar plants.

Mr. G. W. Hall interposed doubts of the correctness of this theory. He had grown one plant on the same ground for twenty years following. On the subject of lime he would mention to the meeting one other purpose for which he had found it beneficial. It was to convey an increased degree of temperature to lands about to be cultivated, which it did, if used in a caustic state. His method was to break the lime as small as possible, and spread it on the ground, and then half plough it in, and he found that a greater luxuriance of vegetation was produced.

HOLKHAM CATTLE SALE.

The stock sold at this sale were highly commended, and the prices at which they sold are at once an evidence of the fineness of the breeds, and of good management. Four three year old North Devon steers were sold at an average price for each of £36=$160; other oxen sold at £34; South Down wethers, two years old, at £4.8; yearlings at £3.6, and pigs at £5.6.8.

DESICCATED MANURE.

James Sheppard publishes, in the Mark Lane Express, that he can make it fully appear, by experiments he has made the last fifteen months, that the loss consequent upon the waste of the fertilizing matters annually conveyed by the common sewers of London into the Thames, amounts to nearly £500,000, or more than $2,000,000. By means of a disinfecting powder, the mass of putridity is deprived of its noxious effluvia in ten minutes; and in twenty-four hours a fine rich black mould compost is produced, fit for immediate use, or for shipping, either in sacks or bulk. The disinfecting powder, applied to liquids, absorbs the whole, and forms a black mould, and may at any time be removed without any annoyance to the public, or those employed in its transportation or application to the land. A ton of this desiccated manure is stated to be equal, in fertilizing properties, to thirty-six tons of fold-yard manure. It sells at Paris, where it has been longest in use, at 50*s* per ton, or eleven dollars.

An establishment has been made at New-York, by Mr. Minor, for converting the filth of that city into fertilizing materials for our lands, by means similar to those suggested by Mr. Sheppard; and high considerations of cleanliness and health, as well as those which appertain to rural economy, and the productiveness of the soil, forcibly concur in inducing us to wish success to the undertaking. These facts certify to the farmer, that there is fertility and value in every decaying animal and vegetable substance about the farm; and should admonish him to husband and apply them to the soil.

To Correspondents.

STEEPING SEED WHEAT.

We have two communications from Mr. J. Hathaway, persisting in his notion, that the germinating power of Italian wheat is destroyed by steeping it a few hours in brine; though Mr. H. admits, that his results might in some measure have been produced by the grain having been passed through a smut machine. On the other hand, Mr. Hathaway's neighbor, B. P. Johnson writes us, that he soaked the seed for six acres, in a pickle as strong as he could make it, to which he added salt petre, for fourteen hours, and that he never has known wheat come finer and better. In another case his wheat was soaked twenty-four hours, in brine that would bear an egg—and afterwards remained in a barrel ten or twelve days, was then sown, and gave a product of 24 bushels to the acre. We have other notices to the same effect, which it is hardly necessary to detail, as we feel a perfect confidence, from the ten, nay hundreds of thousands of trials that have successfully been made, that steeping seed grain in brine, and liming it, does not destroy its vegetating principle. Yet there is one other case we may quote, which, if there were doubts remaining, would seem to set the matter at rest. Mr. Medary, editor of the Ohio Farmer, steeped the Italian wheat *eighty-four hours*, in a warm temperature, in a pickle so strongly saturated with salt as to coat the grain—and yet *every seed grew.* In another instance, the seed remained in the liquid, or brine, *three weeks*; and of this, too, every seed appeared to grow.

While on this subject of steeps, we will detail a fact communicated to us by Mr. B. V. French, of Braintree, Mass. He steeped seed corn in a solution of salt petre, and planted some of it upon dry, and some upon wet ground; not more than a tenth of the latter grew, while seed not soaked, planted upon wet ground, came well. The steeped seed planted upon dry ground, came up almost without a failure. We leave to naturalists the solution of the questions, why Mr. French's soaked corn, planted in wet ground, and Mr. Hathaway's brined wheat, did not grow. They seem both to be exceptions to a general law.

"*A subscriber*" is informed, that T. A. Knight, the distinguished horticulturist, is dead, and of course cannot answer his questions.

"*A Winchester Patron*" is informed that we do not understand what he means by "tinning" his plum and cherry trees, to prevent the ravages of the curculio. This insect is furnished with wings, and does not, we believe, crawl up the body of the tree. We repeat it, hogs and poultry, if suffered to range among the trees, are the best security we know of, against the curculio which blasts and destroys our fruits. The insect which injures the foliage of the gooseberry, may be destroyed, or avoided, we think, by dusting the bushes with lime, or sulphur, or sprinkling them with a weak brine, occasionally.

Horn-ail—To prevent this, Mr. W. Hardrick, of Bainbridge, wishes us to say, he cuts off only half of the bush of the animal's tail! Rather a dubious preventive, we think.

Rohan Potato and Fruit Trees—J. D. Legare, of Grey Sulphur Springs, Va. wishes us to advise him, to whom he shall apply, at Paris, for Rohan potatoes, and fruit trees. All of these we can furnish to Mr. Legare, as we are growing them all for sale in our grounds; but if Mr. L. is particularly desirous of obtaining them from France, we recommend that he apply through Messrs. Vilmorin, Andrieux & Co. Seedsmen, Paris. As to the character of the Rohan potato, we have no hesitation in saying, that, according to the seed sown, it is far the most productive of any variety we know. We cannot judge so well of its quality for the table, never having tasted of but one. We should class it *second*, though others class it *first*, among our good northern potatoes.

Clover Seed—John Young, of S. Carolina, asks information as to the best method of separating clover seed from the chaff. This operation is performed at the north, after the heads have been beaten from the stems with a flail, by machines, propelled by water, horse, and sometimes by manual power. There are several kinds of machines used for this purpose. Burrall's, (see Cultivator, vol. II. p. 130.) with the attendance of one man, cleans from 16 to 32 quarts of seed in an hour. Price of machine $60.

☞ We beg leave to observe to our brethren who conduct agricultural journals, that the "Hints to young Farmers," are original in the Cultivator—and that *we* design to quote or credit what we borrow from others.

The conqueror is regarded with awe; the wise man commands our esteem; but it is the benevolent man who wins our affections—he alone is beloved.—*Fr.*

Gaming is the offspring of avarice and the father of despair.—*Fr. Prov.*

CORRESPONDENCE.

Climate, &c. of South Florida.

NUMBER TWO.

Key West, July 4, 1838.

The soil of South Florida, especially at the cape, is generally considered the very essence of barrenness. The process of reasoning is, that inasmuch as it will not profitably produce those crops which our fathers were accustomed to raise, it is therefore good for nothing. It is true that in that vicinity there cannot probably be found more than five or six acres in any one body, of a similar character to the rich soils of the north. And these small spots are so few and far between, that if they were indeed the only valuable lands in the country, the whole of it, as General Jessup fretfully says, had better be surrendered at once to the savages and wild animals that now roam there. But happily there are many people of intelligence who would be glad to purchase these worthless lands of the government, and become actual settlers on them for life; leaving to those who are content to follow the footsteps of their predecessors, the privilege of thronging "westward ho!" to raise wheat upon the luxuriant lands of Michigan, or cotton in the speculator's paradise of Texas. And these people esteem it a blessing that neither sugar nor cotton can be profitably cultivated in the country which they have chosen before all others for their permanent homes.

The face of the the country is diversified by ridges of pine land, intervening dry savannas, occasional hammocks, and the wet prairies of the everglade; each of which divisions I intend to describe as particularly as possible. The substratum of the whole country is a solid bed of limestone of unknown depth, but so soft as to be easily broken and dug up by a pick axe, or hewn into form by any suitable instrument. It becomes much harder and white by exposure to the atmosphere.

The pine ridges are the most elevated parts of the country; but I suspect they are nowhere more than twenty feet high. the timber is a kind of pitch pine, with straight small trunks, and irregular branching tops. Their general heighth, were I to venture a *guess*, cannot be more than seventy or eighty feet; and the largest of them do not exceed two feet in diameter. Their trunks are free from limbs, and the ground is entirely unobstructed by underwood, and clothed with grass; thus affording extensive natural pastures for grazing animals, and beautiful fields for horse-back riding, hunting and other amusements. The indigenous grass of the country is not the best that the soil is capable of producing. The Guinea grass has been growing there for many years, and thrives to great perfection. The soil is in some places deep enough to admit of ploughing; but in others it is so shallow and stony as to prevent even the use of the hoe.

The savannas, lying between the pine ridges, are in some places clothed with a thick stout growth of rank grass; and in others, with a more thin and stinted kind, indicating a poorer soil. But what the soil is, I cannot say, never having examined it. These savannas are generally dry, though they are subject to occasional inundations, for a few days in the rainy season, by the fresh water from the everglades. As the glade rises, its surplus water runs over into the valleys, in which it is dammed up by a pine ridge; in some places but a few rods in width, running along the shore of the bay. Behind and parallel with this ridge, for ten or twelve miles in extent, lies a savanna connected with these, which receives the overflowing waters. In all these valleys the water stands until it can find its way to the bay through underground channels, which are not sufficient to conduct it off as fast as it accumulates.

These facts naturally suggest the important inquiry whether the dyke which dams up the surplus waters might not be easily cut away—and if so, whether the current of water which the opening would create, would not of itself wear a number of channels deep enough to admit water at all times of the year, to pass from the glade to the bay. But admitting that artificial streams may not be furnished so easily, it is reasonable to suppose that some such can be made with no great expense in digging away the obstructions which the water alone may not be able to remove. Thus water power would be created in various places along the shore of the bay—the very points at which it would be most useful.

The wet prairies of the everglade would also by this process, in a great measure, be reclaimed, thus rendering large bodies of valuable land susceptible of cultivation, which otherwise would remain useless. These prairies, in some places extend further than the eye can reach, and are so uniformly level, that by lowering the waters of the glade not more than one foot, immense tracts of them would be fully and permanently drained. Though these results are as yet uncertain, they are sufficiently probable to command the attention of the public, and to justify the consideration here given to them.

The hammocks are clusters of dense wood land of live oak, mastic, wild fig, dogwood, gum elemi, cabbage palm, and various other kinds, with an undergrowth so thick as to be almost impenetrable. They lie generally on the borders of streams or fresh water springs, to whose enriching moisture they perhaps owe their existence. The soil contains an abundance of vegetable matter, and in some places, a suitable mixture of clay, sand, and lime to constitute a rich loam. More often, however, it is merely sand and vegetable mould, which, of course, by constant and careless cropping, soon loses its richness. It produces abundantly all kinds of garden vegetables, which are about all the inhabitants have yet attempted to raise. On these lands also abound the red mulberry, and an indigenous species of the grape, which is said to be very good, as well as various other kinds of wild fruit of but little value.

Such being the character of the soil, the reader will naturally ask,—what are the inhabitants of such a country to do for a living? I proceed to answer.

1st. The manufacture of the Florida arrowroot has been, and always will be, a profitable business for the residents at the cape. It grows abundantly and spontaneously upon the very poorest of the sandy pine lands. Indeed it is so very unassuming and modest that it will not grow well upon any other; but it seeks and thrives best in the purest white sand where nothing else will grow. Neither does it ask any favors of man for its planting or cultivation, but freely invites him to the harvest after it has planted and raised itself. The seed which is unavoidably scattered by the process of gathering the roots, produces a new crop, better and more plentiful than the first. This improvement is probably the result of the cultivation effected by pulling the roots. It is manufactured with very little trouble. Many families are accustomed to grate it upon a tin grater, and prepare it in the same manner as potato starch is made; and thus they realize a decent profit. At the commencement of the war there were two mills in the vicinity of the cape, each propelled by a single horse. By the aid of such mills, I am informed by those who have followed the business, that five men with a horse and cart, can dig, gather, manufacture, make the boxes, and pack ready for sale, four hundred pounds of arrowroot per day. The price of the article is yet unsettled. It has varied at wholesale in this market from six to sixteen cents; and it is the opinion of our most intelligent men that the demand for it will increase, as its value becomes more generally known. Now, after making liberal allowances for the price it will permanently have, and the expense of manufacturing it, there can be no question that it will afford a handsome profit to all who may turn their attention to this branch of business. If then the white sands of Cape Florida will spontaneously produce valuable crops, why are they inferior to the rich wheat lands of the north, on which man is doomed to earn his bread by the sweat of his brow at incessant toil? and why are the former called poor, and the latter rich? The proof of a soil is not in the name but in the produce.

2d. There is much reason to believe that the making of silk, may become a good business in South Florida. The native mulberry abounds in the hammocks, and will grow well in the pine lands. The white and the Chinese mulberry have both been introduced here, and have found a genial soil. And as we have no frost to destroy vegetation, the silk culturist may follow his business during the whole or nearly the whole year. It is true that this is yet an untried business with us; but it would seem that if it can be made profitable at the north, with only one brood of worms in a year, it may become more so here, even with very liberal allowances for unforeseen difficulties. I am not aware that any method has yet been discovered, to obviate the supposed necessity of keeping the eggs through a northern winter before they can be hatched. But while I confess my ignorance on this point, I cannot believe that such a practice is necessary. It is unreasonable to suppose that eggs of worms raised where there is no winter, will not hatch in due course of time. It must be that a few well directed experiments, in this climate, will disclose some mode of keeping up a constant and immediate succession of broods of the silk worm, sufficiently regular and perfect, to render the silk business much more profitable here than at the north. Mr. Charles Howe, of Indian Key has made a few cocoons, from northern eggs, which are said to have been of a good quality. He found no difficulty in keeping the eggs from hatching during the summer as long as he pleased, or in hatching them whenever he chose to expose them for that purpose. But on *one* occasion he exposed fresh laid eggs, as he had been accustomed to do his old ones, and they did *not* hatch; and whether he pursued the experiment I am not informed. If, however, the silk worm can propagate its species in this climate, which cannot be doubted; and if we can prevent its eggs from hatching as long as we please—and experiment has proved that we can—we are very near to the wished for discovery, if it has not already been made; and we may calculate with confidence upon the silk business becoming a profitable employment in this country.

3d. The raising of tropical fruits must in a few years become another profitable branch of business here; and we shall be under no apprehension of disasters from frosts, which have proved so fatal to the orange trees at and about St. Augustine. Neither can we fear that this branch of business will ever be overdone in Florida, when we consider the limited extent of territory in which it can be followed, and the numerous markets which the northern states afford. While man has an appetite for the good things of this world, the inviting fruits of the south will always be in demand, and will necessarily command a price sufficient to insure their production and their transportation to market.—Some little time will be necessary to raise the trees; but when this is done, a certain and easily earned income is the inevitable result.

4th. A new branch of American agriculture or manufacture is about to be tried at Cape Florida by Doctor Perrine, late American consul at Campeachy in Mexico. He is sanguine in the belief that the culture of Sisal Hemp, will soon become not only a source of profit to individuals engaged in it, but also of great importance in a national point of view, in supplying a superior article of cordage of every kind and size for our shipping; a cheap, and strong material for the manufacture of every quality of cloths from the finest linen to the coarsest cotton bagging. The doctor is well acquainted with this subject, and has spent several years in preliminary preparations for commencing this business; and people of intelligence to whom he has exhibited specimens of the article—the mode of manufacturing it—and the nature of the plant from which it is obtained, are strongly impressed with the belief that he must inevitably succeed in this great undertaking.

The worst description of land in South Florida—that which is even inferior to the white sand which the arrowroot lays indisputable claim to—is the very soil in which this hemp plant, or properly speaking, the agave, best thrives. Indeed this soil to which it is natural, cannot properly be termed soil at all, for it is little else than stone. This species of rocky land is abundant in this section, particularly on the thousand islands that everywhere surround us, and the extreme limits of the main land. Should this branch of business be found profitable, our Florida archipelago, long the dreaded hold of piracy, and now wild and waste, will soon swarm with a useful and industrious population, and become a paradise indeed.

For the purpose of aiding the doctor and his friends in this undertaking, in connection with culture, and acclimation of tropical plants in general, the legislature of Florida, last winter, incorporated a company with a capital of $50,000, entitled the Tropical Plant Company of Florida. Nothing now delays the commencement of operations except the Indian war. Indeed the doctor had already growing in boxes near Indian Key, several hundred foreign plants ready to be transplanted at any moment.

Besides these distinct branches of business, a few people may profitably engage in the sawing of lumber. For this purpose a gentleman expecting to settle at the cape, now contemplates the erection of a steam mill there, in case suitable water power cannot be found. The settlers may readily be supplied with building materials, so indispensable to all countries in the progress of improvement.

Furthermore, there are numberless auxiliary means of providing the necessaries of life in this country. An abundance of fish, turtle and oysters may be had at all times, merely for the trouble of taking them. Turtle on this coast supplies the place of beef at the north, and it is just as common. They are caught in great numbers and put in enclosures, and fed on grass; whence they are taken and killed as occasion requires. Horses, cattle, and sheep ask no favors of man whatever; but give them their natural and inalienable right of "life, liberty, and the pursuit of happiness," and they will "multiply and bring forth abundantly in the earth;" and then if man choose, they may be made to supply his table or his pocket with the needful. He need not labor in the heat of the sun to make artificial pastures for them in summer, and provide a mountain of hay for their winter store; nor need he brave the piercing cold, for eight long months, in dealing out to them the treasured produce of his summer toil. No—nature obviates this necessity in tropical Florida, and freely feeds upon her verdant bosom the animals she has given to man. Garden vegetables, too, which ought to constitute the principal portion of our food, are raised with surprising little labor. Peas of an excellent quality, grow abundantly on bushes like northern currants, and bear continually. They have also a superior species of white bean growing upon a vine, which though it would be annual at the north, is perpetual here. When once planted it is planted forever. A man might live comfortably on vegetables alone, without devoting to their cultivation more than one day in a month. Sweet potatoes alone might furnish half his constant food, and still be considered a luxury. They who have only eaten them at the north, can have no idea of their true value in their native clime. They will not keep good like Irish potatoes, but generally spoil in a short time. When fresh, they are often exclusively eaten for an entire meal, though the table be well supplied with other kinds of food.

There is another valuable vegetable now growing to perfection at the cape, which not only *may* constitute the greater portion of one's food, but actually *does* furnish almost the entire subsistence for the negroes on the plantations of Cuba. I mean the plantain, of which there are four species. The plant itself is extremely beautiful—fifteen to twenty feet high—leaves, five to ten feet long and one and one-half to two broad—thin, soft and silky in their texture, and of a deep, glossy, green colour. The banana and one other species, bear only one large bunch on a stalk. But it is indeed a large one—as much as a half grown boy could well shoulder, and weighing often times over sixty pounds. In shape, the first resembles the cucumber—about five inches in length and one and one-half in diameter; and from one hundred to two hundred of these grow in a bunch, as closely as they could be packed in a basket. They are covered with a thin skin, which when the fruit is ripe, may be peeled off with the fingers as easily as if it were a paper envelop. The food is then ready to be eaten from the hand, and consists of one solid mucilagenous pulp—mild, easy to digest, and inviting in its flavor. The banana is more fruit than food; but the plantain is more food than fruit, and is generally cooked and eaten at meals.

Both species are propagated by planting the suckers that spring up around the parent stock. After growing eight or nine months, the flower puts forth, and in about three months longer, the fruit is perfected. When this is gathered, the stalk is cut down to the ground, to make room for the young plants which are growing up like a family around a fruitful mother. The first born of these is just putting forth its flower when the fruit of the parent stalk is ripe. In this order they proceed continually. But as all the stalks do not ripen their fruit, or need not be planted, at the same time, a field of plantain and bananas need never be without a constant succession of ripe fruit.

Under all these facilities for easy living, it strikes me that no one need be apprehensive of starving at Cape Florida. L. W. SMITH.

Use of Plaster on Fruit Trees—Canker, &c.

Liverpool, July 23d, 1838.

Jesse Buel—Sir—Two of my plum trees in my garden, five years since, were heavily laden with fruit; the two succeeding years they flowered, but bore no fruit. Last year and this I dusted ground plaster over the tops, while in full bloom; the effect was they fruited well both seasons.

Black Canker, (I believe you call it,) *in plum trees.*—For about three years I have been in the habit of cutting off the limbs, or that part affected, whenever I discover any canker on them: the consequence is my plum trees are green and thrifty, while I see many of my neighbors' trees entirely killed by canker. I do not burn the parts cut off, as one of your correspondents recommends, but it may be well to do so, as some of my canker bunches contained worms. I have to regret with you that our legislature has done so little, in aid of the great agricultural interest of our state. Administration and anti-administration, all seem equally culpable in this respect. We have sent a majority of farmers to the legislature, with but little effect; they too have been tardy in legislating any thing to aid the all important business of farming: this is a no party business, and would it not, I ask, be well for all political parties to select their candidates for the legislature with more reference to this subject, who will truly represent the great agricultural interest of our state? For it cannot be doubted that a vast majority would agree with you and me that the legislature should do something more efficient to give a stimulus to the agricultural interest of our state. It is of little use to petition the legislature, unless we have representatives at our capitol who will listen to our prayers. I observe you notify us that the three first volumes of the Cultivator are to receive a new edition. Why not include the fourth volume; so as to have all the small size in one book. I for one would like to obtain all the numbers up to the enlarged volume, and I believe others would.*

JONATHAN P. HICKS.

Culture of Spring Wheat, &c.

Judge Buel—Sir—I am much more in the habit of ploughing than writing, but thought that I would make a few statements relative to raising spring wheat. I sowed about fourteen and an half acres last year; the return four hundred and sixty-eight bushels, the most of it Italian spring wheat: five and an half acres in one piece yielded two hundred and ten bushels, about forty bushels to the acre. There was some difference in the piece; it was thought by the reapers that about two acres of the piece would yield full fifty bushels to the acre: land ploughed once; except about an acre, which was the poorest of the wheat. The land had lain to pasture I should think about six years. I sold the wheat for two dollars a bushel. I believe that I could have sold ten times as much if I had had it. The rest of my Italian wheat was sown on poorer land, and did not yield so much. The return of all my wheat thirty-three bushels on an acre.

I will now state to my brother farmers what I think the most profitable way of preparing land for spring wheat, which I can do for four dollars an acre. As labor is dear it is of importance to use economy. In the first place, let about all the stones be taken off: if the land is in good heart, put on about ten or twelve loads of unfermented dung; if the land is somewhat worn, fifteen or sixteen; if it is very much exhausted, twenty or twenty-five will be all the better; this we shall make no account of; all this must be done if you sow winter wheat : plough the land once, the earlier the better, and do it well: make no bauks, as the farmers say, but let it all be turned over; that you can do for two dollars Give it a good dragging, no matter how soon: let the sheep and cattle run on it as much as they please, all summer: go over it now and then with your drag and cultivator, so as to keep the grass and weeds down: by fall, your land will be very mellow: all this you can do for one dollar more. Sow your land, as early as you can in the spring, with Italian wheat, or Siberian spring wheat, which should be very clean; which you may do in the following manner: let your wheat be put into a tolerable strong brine the night before; put about a bushel in a box, or tub; put in as much lime or plaster as you can make stick to the wheat; lime is rather the best: if the land is rich, sow at least two bushels to the acre: I sowed ten rods of my piece two and a half or three bushels to the acre: the wheat was monstrous, and I could not perceive but that it was just as plump as any part of the field. I should think that the return of an acre of such wheat would be at least sixty bushels. As I stated, sow as early as you can: after sowing, go over your land both ways with the cultivator, and once with a fine patent drag: if the land is dry, let the roller pass over it once; this you can do for one dollar more, which makes four dollars an acre, about half the expense of preparing land in the old way for winter wheat. Your land will then be as mellow as ashes. If you have done the work well, you may calculate for about forty bushels an acre the first year. After harvest, as soon as you can, you may plough the same land again, turn the stubble all under, which will be a pretty good dressing for the land. I practice what I call a foot on my plough, to prevent it from clogging up, a piece of wood about eighteen inches long, perhaps six wide and four thick, with a mortice in the middle near the end of the beam, with a wedge the upper and under side; it will crowd the stubble down before the point of the plough, and you will plough it about as well as if there was no stubble there. Drag your land once or twice in the fall: sow it the next spring, in the same manner as before: you may then calculate for about thirty bushels an acre. I would also recommend to sow the same ground the third year,† in the same manner: you will be likely to get about twenty bushels an acre. Seed it down the third year with clover, if you want it for pasture; if for meadow, clover and timothy: in about three or four years more you may plant the same land again. Perhaps it would be better to put different sorts of spring wheat every year; I have sown five different sorts of spring wheat this year; I have the Italian bearded, the Italian bald, the Siberian, the old white chaff, and a sort that I call the Syracuse wheat, said to be a great yielder, sixty-two pounds to the bushel: the season was remarkably wet; and this season I began to sow the thirteenth of April and finished the twenty-fifth of May. I thought I should not have half a crop for a long time, but lately it has done remarkably well: if the remainder of the season should be good, I should think the crop would be abundant. I have but little doubt but that, in the great wheat growing districts in the west, where the winter wheat begins to fail, or on the rich prairies, that the Italian or Siberian wheat would yield forty or fifty bushels, in a common season, where the work was done well.

One thing more, Judge Buel, and then I have done. I have read much in the Cultivator and Genesee Farmer about bone manure, but how shall we prepare it? It has been said that it could be ground in a plaster mill: accordingly I collected a number of bones last summer, carried them to Ithaca eighteen miles; the man said that he thought that he could grind them, and he would take pains and do them well, in a short time: I sent after them by my son: he informed him that it took him about half a day, with another hand with him, and he could not afford to grind them short of ten or twelve shillings a bushel; and they made such a smell the people wondered what he was about in the village; but he charged me only twenty-five cents a bushel.

I have lately heard that to mix a little lime with straw, as you thresh it out, will make it rot very soon. I should be glad of some information about that. I would also inform my brother farmers that wish to raise the Italian spring wheat, that it is likely I shall be able to supply some of them with seed this year: I expect to thresh my wheat with a machine this year, immediately after harvest: I shall clean it twice over, in a first rate mill, and make it very clean for seed: it is likely that I shall have a thousand bushels, if the rest of the season should be favorable. Any letters addressed to me, from any part of the country, post paid, will be promptly attended to: letters may be directed to Jonathan Edwards, town of Virgil, county of Cortland, state of New-York. Perhaps I have written more already than you will be willing to print, or your readers will have patience to read. You are at full liberty to leave out any part, or the whole of it, as you may think proper. I subscribe myself yours sincerely.

JONATHAN EDWARDS.

Cheap Horse Power and Thrasher.

Butternuts, July 20th, 1838.

Sir—Farmers are aware of the loss of time and labor attending the practice of thrashing with flails: and thrashing machines would be more generally introduced were they not too expensive for the means of most of our farmers; for this appears to be the principal cause why they do not provide themselves with them. We have a machine and horse power, built by our neighbor, Mr. Botsford—cost fifty dollars—which will thrash one hundred bushels of wheat in eight hours, attended by three men and a horse. We have done our thrashing with one horse, but two or three may be attached if necessary. The machine may be attended to very good advantage by a man and boy. It has been examined by several farmers and mechanics of our vicinity, and has uniformly met their approbation. There are several of our neighborhood who will each have one built the ensuing winter. Any kind of machinery may be attached to it capable of being propelled by one, two or three horses. We want a machine for shelling corn, which may be attached to it. Can you direct us?* Very respectfuly yours.

NELSON B. PEARSALL.

"Where did he get his Education?"

Lake C. H. Ia. July 15th, 1838.

J. Buel, Esq.—Dear Sir—This question, which has so often been applied to the writer of this article, has just been brought forcibly to mind by (for the first time) reading in your first volume, an address to young men, in which occurs this golden morsel:

"*Although we may be learned by the help of others, we can never be wise but by our own wisdom.*"

That is our own exertion. There is also another article in the same volume on "Self-Education," by John Neal; which is worthy of a republication in every paper in the union.

It is a settled point that some of the wisest men who have adorned our country were self-educated. Mechanics and farmers *have* "found time" to acquire a useful education. Every one of them *can* still find time for the same purpose, if he will. It is self-exertion that acquires self-education. Who that perceives that the knowledge which his neighbor possesses, and which gives him such a decided advantage in the world, is within his own reach, that will not extend his hand for the golden treasure?

What shall we do to incite young men to exert themselves to procure an education by their own exertions? For they can no longer depend upon government. Not one half of the states have even provided for the lowest grade of schools. And in those where the common school system is in the best operation, what except the veriest rudiments, the mere A. B. C.'s of useful knowledge, can be learned.? 'Tis true this is a good foundation, but we want something to incite the community to add those elegant superstructures which ornament the world. We should have, we can have, shall I add, we will have, in every county and principal town in the United States a well founded agricultural school, in which young men and girls can acquire such an education as will be USEFUL. Not a piano, French, Spanish or flower daub education, but one that will make the men scientific farmers and mechanics, and intelligent public officers and *acting* legislators, and the women fit to become the honored and husband-honoring wives of such citizens—who will never be ashamed to tell their daughters, that they obtained the education that has ever since rendered them ornaments to society, in a manual labor school, where, by their daily toil, they earned their daily acquirements. But let not toil be construed slavery or drudgery, for that never should be in any family, and much more in a school. Useful and healthy labor, judiciously applied without slavish toil, should afford all the necessary means of enjoying life. If ever the false pride of labor hating, and the false and foolish, and for all practical purposes of life, the present prevailing system of fashionable education is improved, it will be by such schools. There is evidently a growing disposition towards improvement in the agricultural community; but until that disposition has grown to a greater maturity, the great ends and objects of the pioneer friends of improvement cannot be brought about. Would not the foundation of "An American Society of Agriculture," be the means of increasing the little band of pioneers now in the field, until every town boasted of its useful agricultural school, and every legislature its majority of agriculturists, who would feel proud of being dressed, and elegantly too, in American silks and broadcloths?

Such a body of men would not need to be petitioned, year after year, before they would enact laws for the purpose of preserving, improving and strengthening the base upon which rests the whole superstructure of civilized society. Fearing I am falling into a popular error, a tedious, lengthy list of words, I close abruptly. Your friend.

SOLON ROBINSON.

The Cotton Culture, and its Profits.

Marlborough District, S. C. July 15, 1838.

J. Buel, Esq.—A friend has just handed me the Cultivator of December, 1837, with the request that I would answer the following questions, propounded by your Princeton, (N. J.) correspondent, on the culture of cotton, &c.

Question 1. *What soil and climate is the most suitable for cotton?*

Answer. The first branch of this question would be difficult to determine conclusively, there being almost as many different opinions as you would find planters. But for myself I should prefer a mixture of clay and sand in equal proportions, and for these reasons: Such a soil has the power of absorbing both heat and moisture in a greater degree than where clay much predominates; the young and earlier growth of the cotton, hastens more rapidly to maturity (which is a matter of the first importance)—is more easily cultivated—and is more certain in obtaining a *stand* with an unfavorable spring. The climate most suitable for the growth of cotton, is between 30 and 35 degrees.

Question 2. *What kinds of seed are found in the southern states to be the most productive and profitable?*

Answer. For upland or short staple, the Alverado or Petit-Gulf is preferred, as being easier gathered, yielding more, and having a longer and stronger staple than the green seed and other varieties. I know not of any particular kind preferred by the Sea Island, or long staple planters.

Question 3. *What is the best method of, and the best time for planting?*

Answer. The usual method is to drill upon the bed with a very simple plough made for the purpose, of a piece of timber a foot and a half in length, and from one inch and a half to two inches thick, and a foot in width; there is then attached another piece lengthwise on the centre of its bottom, so as to make the drill from two to two and a half inches in depth and width at top, sloping to a half inch at bottom, with two handles, a beam and helve, and the plough is complete. The reasons why the drill is so made are these: it gives sufficient space at top for the seeds to enter, without requiring the sower to stoop too much; and at the same time brings them to a narrow compass at the bottom, which is a very great advantage in after culture—enabling you to plough nearer, and thin out with much more regularity and exactness.—After the seed is sown in the drill it is sometimes (in very stiff lands,) covered with a small harrow; but when the soil is light and will permit it, a plough similar to the one above described, without the longitudinal piece at bottom, answers very well the purpose. The best time for planting will much depend upon the land and season. The usual time in South Carolina, is from the first to the tenth of April. Farther south they plant a little earlier.

---

*The three first volumes are re-printed on a page to match with the fourth, of which latter we made 25,000 impressions, so that the whole may be had bound together, or in two vols.

†Bad! Bad! Very bad! 40—30—20!

*Yes—to Thorburn's, Albany.

Question 4. *What tillage must precede and succeed the planting? can two crops be made in a season?*

Answer. It is necessary that the land should be well pulverized, and the bed of an even and uniform height. The distance between the rows and height of the bed, will depend entirely upon the fertility of the soil and its location. For some, three feet distance is sufficient; and in others, six is not too much. In the drill it may be crowded very thick, say from six to eighteen inches—but it is indispensably necessary to give it sufficient space the other way—light and air being all-essential in every stage of its growth. When the cotton is fully up to what is called a *stand,* a hoe from six to ten inches in width, (the size depending on fertility of soil) is passed through it, leaving three or four stalks at a place. This *chopping out* as it is termed, is immediately preceded or succeeded with the plough. This ploughing is not a deep one—it is chiefly intended to stir the land a little, and throw whatever young grass may have come up on the beds into the furrow, thereby lessening the work of the hoe very much. The next working with the hoe, is an exceedingly important one. It takes a very skillful and experienced *hand,* to do an hundred rows, an acre in length, as it should be. The bringing it down to the permanent *stand* is tedious; and very much so if it should be a little grassy, (as it is but too apt to be at this stage.) The plough immediately follows and dirts the cotton, cleaning out the entire space between the rows, leaving it in beautiful order and appearance; the plant now having four leaves. This routine is continued throughout the whole season. The culture should be continued (at least with the hoe) until the middle of August; it is sometimes necessary to extend it even beyond that period, when the spring is very backward, and the fall very wet. The kind of plough used is of cheap and simple construction. Our own blacksmiths and carpenters are usually the manufacturers. Two crops cannot be obtained in a season; for I believe there is no portion of the vast cotton growing region, from the Sabine to its utmost northern limits, in which it is not occasionally cut short by the frost.

Question 5. *When and how should it be gathered, and how can it be most expeditiously cleaned, pressed and prepared for manufacture or exportation?*

Answer. It should be gathered so soon as it commences opening; and with the hand. The labor of gathering and preparing a full crop for market, is nearly equal to its culture. Surely not so heavy, but tedious; and nothing can be done at it in wet weather. The season too is not congenial to the disposition of the negro; he is sad and spiritless at a temperature that you would feel but comfortable—whilst his most joyous peals of laughter would be heard under the scorching rays of a meridian sun. It is cleaned with a gin, (Whitney's invention) cheaply and expeditiously, either by water or horse power, from 1000 to 1500 pounds of clean cotton per day; and then packed with a heavy wooden or iron screw; and so it leaves the planter's hands.

Question 6. *What is the fair average yield; the cost of culture, of bagging, of machinery, &c. the nett profit per acre? A numerical statement is desirable.*

Answer. This question I cannot so fully answer as your correspondent desires. It would be difficult to graduate so many items of expense to a single acre—and ascertain its nett profits. The following statement however, is not far from the truth; it is at least a safe one.

Average yield per acre (clean cotton,) 150 pounds: cost of culture, $6: cost of machinery, 12 pounds of cotton: cost of bagging, rope and twine, 75 cents. Nett profits can be ascertained from price of cotton.

Question 7. *To what diseases is the cotton of our country liable, and how may they best be remedied?*

Answer. The diseases to which our cotton is most liable, are the *rust* and *rot,* for which we have found no remedy. The *rust* attacks the leaves, and causes them to shed off. The *rot,* the bowls, and effects them as its name indicates. There are various and conflicting opinions as to the causes of these diseases, which are useless to enumerate, as I believe they are not understood.

I have thus attempted briefly to answer the *queries* of your correspondent, which may appear unsatisfactory. But sir, if you have any idea how little of science or of skill is used in perfecting a cotton crop, you will agree with me that but little can be said about it, except in the way of pointing out its abuses, and suggesting remedies for its improvement. There never was a wider field for agricultural science to exert its beneficent effects, than on the cotton growing states of the south. With a soil fertile in the extreme—and operatives the most cheap and efficient in the world—commanding a staple which gives vitality and existence to industry in a thousand forms—in almost every portion of the universe—they have scarce as yet progressed one step towards improvement. The land is tilled as if its sources of fertility were inexhaustible, and with the most prodigal waste of the choicest and richest blessings, that an all-wise and beneficent Providence could confer. The system (if the term can be applied) is a most suicidal, and ruinous one; it is exhaustion—exhaustion—continual exhaustion, without any return. If you should meet with an exception, as (you sometimes would) it but shows in more glaring colours the prevailing practice. To sow a rich field in January or February with oats, reap them the first of July, and plant down in corn, I have known to be done by those who were esteemed good planters. To plant the same field in cotton or corn for years in succession, is very common, and that too without one load of manure. And if it should be changed it is not for the better. If it will bring any thing at all, it will never do to let it lay out,—and so it is thickly sown in oats; after being reaped clean, (the temptation cannot be resisted) all the hogs, horses and cattle must be turned upon it, producing the most injurious effects. This is sometimes called resting land. What, sir, do you think of it? I mean always to be understood as speaking of the prevailing custom. There may be found (as I have before observed,) a few honorable exceptions in every district of country, and if I am informed correctly, the farther south the fewer. No excuse can extenuate so wretched a system; its parallel is not to be found in any age or country. We need not be told of the energy and enterprise which stimulates a young and vigorous people—that the age is one of rapid and incalculable progress—that its spirit is not to be checked or stifled by the cold and formal rules of science and system. But it is here we can trace the source of the very worst system of agriculture that can be imagined. It is to this headlong energy and enterprise, strengthened and quickened by the insatiable desire of gain, which is laying waste, as with the hand of the destroyer, the entire cotton growing region.

Yours respectfully,
A COTTON PLANTER.

On the Gearing for Working Oxen.

J. Buel, Esq.—Dear Sir—In perusing the April number of the Cultivator, which came to hand but yesterday, I was greatly pleased with a communication, made by Mr. David Allison, on the subject of "Yokes for Oxen."

Although, within the last twenty or thirty years, some improvements have been made in the gear and harness of working animals, especially in those for horses, yet it is believed that some may even yet be made, and particularly in those for oxen.

Humanity, as well as self-interest, would induce a desire in every *rational* owner of laboring beasts, to make their working gear in such form, and of such materials, as would be most convenient for the animal, the most accommodating to the form of his body and natural motions, and attached to him in such a manner as to enable him to exert his strength to the best possible advantage of his master, and the least irksome to himself.

As to the ox, the author of nature seems to have placed the seat of his strength in his head and neck. To these parts, therefore, reason dictates the propriety of attaching his working gear. The question then arises, of what materials, and of what form, shall this gear be constructed, and in what manner attached to him?

In our country, the uniform gear or harness of this useful animal has been, and yet is, the yoke and the bow. In remarking upon a usage so long practised by our fathers and grand-fathers, I would speak with diffidence, while suggesting reasons for my objections to this mode. Where, I ask, can be found an experienced farmer, whose better feelings have not been pained, by seeing the galled and swollen neck of his patient ox, occasioned by the chafing and pressure of the yoke and bow? And how frequently bloated by the obstruction of his breath, caused by the same pressure! If the feelings of the master, on such occasions, are pained, how great must be the sufferings of the poor animal, while compelled to press his neck, swollen and sore with raw cracks in his skin and flesh, against his wooden yoke? The peculiar form of the neck of the ox is such, that it is impossible to construct a gear of wood, or of any other rigid *material,* which shall come in contact with, and bear equally upon, every part of the neck. The perusal of the well written and interesting communication of your correspondent, Mr. Allison, has induced and emboldened me, to offer you this article. He closes by observing—"I have heard that there are modes of bringing the draft on the head instead of the shoulders, practised in the Spanish provinces, the particulars of which I should gladly become acquainted with."

I take much pleasure in stating what I learned on this subject while residing in Spain, nearly two months, in 1828. I embraced every opportunity afforded me to become acquainted with whatever came in my way relating to the agriculture of that kingdom. As the uniform mode of their harnessing or gearing their working oxen was new to me, I took more particular notice of it, and examined it more critically. I had many opportunities for seeing their oxen work, as well with loaded carts on the roads, as at the plough in the fields. Upon the whole I could not resist the conviction that the Spanish method of harnessing their working oxen, is, in all respects, preferable to that which is practised in our country. I will endeavor to describe it, and suggest such reasons as operated with me in support of my opinion.

The draught is wholly by the head, to which the gearing is attached. The yoke for a *pair* of oxen differs but little in its length, thickness and form, from that in use with us. No bows, ring-staple or ring are connected with it. The curves of the yoke, where it rests upon the necks of the oxen, are somewhat deeper, perhaps, than those of ours. On the front side of the yoke, two square staples of iron are placed for each ox, eight or ten inches apart from each other, corresponding in point of distance from the end of the yoke and from each other, with the location of our bow-holes. To the inner staple for each ox, a band of strong leather is made fast by stitching. This band is sufficiently broad to fill the space between the swell of the eyes and the but ends of the horns, and is brought round the front part of the head and fastened by a buckle connected with the outer staple. In some instances this band is lined by another piece of leather, with a thin padding, quilted in between the two pieces, in order to render it more pleasant and easy to the head—though I never saw any appearance of chafing or other injury done to the head by the band. The yoking and unyoking are performed with great facility and expedition—it is only to buckle or unbuckle one end of a single strap for each ox.

By this mode of gearing it will be seen that the application of the power of the ox, exerted in the draught of the load, is at the head. As it respects the advantage or disadvantage of holding back on descending ground, I am unable to perceive any essential difference between the two modes, as the holding back in both must be done by the yoke coming in contact with the horns, and without any aid from the bows.

In conversation with a Spanish gentleman on this subject, he remarked, "By harnessing oxen in your method, and making them draw by their *shoulders,* you loose much of the strength of their heads and necks, parts wherein their strength principally lies. Our ancestors in this country," continued he, "took their first ideas about the mode of gearing their oxen for labor, from seeing the uniform manner in which bulls meet each other and fight."

Nature has instinctively taught animals where their strength lies, as well as the best manner of using it in contending with others, either offensively or defensively. The bull presents his head to his antagonist—the horse his heels, and the tiger his teeth.

The facts and reasoning of Mr. Allison are worthy of the careful attention of every farmer in the U. S.—they are *practical.* The use of the single yoke described by him, and the manifest advantages attending it, must, I think, commend itself to every one. But, with due deference, I would submit to his consideration, whether the Spanish *head-band* instead of the *bow,* might not be an improvement?

Very respectfully yours.
SAMUEL WOODRUFF.
Windsor, Conn. August 11th, 1838.

Household Economy.

Schenectady, July 27, 1838.

Dear Sir—Your Cultivator is particularly designed to promote improvements in husbandry. I presume you are equally desirous to aid housewifery.

We often hear lamentations of the loss of fat saved for making soap, by its being in an offensive and spoiled condition, and eaten by maggots—sometimes of the loss of the fat eaten by rats. None of these happen about my house; nor is the fat boiled in ley to make soft soap.

The fat, as it is saved, is put into a cask prepared, and strong ley added to it. As the fat increases, ley is added, and occasionally stirred by a stick kept in it. When the cask is full, the soap is made and ready for use.

The ley cask is filled with ashes for leeching, and drawn off to add to the soap cask, as stated above. When the ley has been drawn off, and by filling with water and draining, it becomes weak, it is used for bleaching, &c.

When the ley cask is emptied, it is filled immediately with ashes, to be used as above mentioned, so that the cask is always in use, by which means it is kept in order, and lasts many years. When left empty, as some persons practise, it shrinks and soon becomes useless. Some quick lime put into the ash cask, near the bottom, causes the ley to be more caustic.

Cedar and white pine make the best casks for ley or soap. The pine should be free from knots and resin, as the ley will incorporate with the resin, convert it to soap, and leave the wood porous and leaky.

When soap has accumulated beyond the wants for soft soap, it is converted into hard soap, by adding one quart of fine salt to three gallons of soap, boiled and put into a tub to cool; then cut it into pieces, scrape off the froth, &c.; then melt it again, (leaving out the ley at the bottom,) to a boiling heat, and put it into a box to cool, and cut into bars for drying. A little resin or turpentine added before boiling, improves the color and quality of the hard soap.

This mode of making soap relieves from the pagan practice of boiling soap at a *certain stage of the moon.*

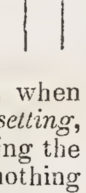
If you think the above will be of much use, you may give it to the public. Most respectfully,

J. Buel. DAVID TOMLINSON.

Fence Making.

Juliustown, N. J. July 14, 1838.

J. Buel, Esq.—Sir—As the expenses of fencing, where the locality of farms requires rails, are often great, I may perhaps advantage some of your readers, by describing a method which I find to be a saving of land, timber, and labor, when brought into a comparison with what is generally called the *worm fence*. To construct a durable and good fence, on what I call the *improved plan*, requires *straight and strong* stakes, of suitable quality, and some seasoned blocks for pins. Trunnels are not wanted. Stakes from seven to nine feet long; pins twelve to eighteen inches, suiting the size of the rails. The pins I make in wet weather or winter season, and also bore holes in the stakes, for a pin on which the bottom rails are laid; this is done with an inch and a quarter or larger auger, agreeably with the number of rails, and their weight or size, as a light or heavily constructed fence is wanted. The lower pin is pointed at both ends, and should be forced in tight, so as to attach the bottom end of the stakes and keep out wet. If for an outside, or fence to turn hogs, the bottom hole in the stakes is bored two feet from the end—if inside or temporary, where hogs or sheep are not to run, two and a half or three feet. To one of these pins, I attach two stakes, and set them in the ground at my beginning, *firmly*, twenty or twenty-two inches, and lay on a rail, the forward end of which will show where to set the next pair of stakes, and thus I lay out the foundation. If I am making a tight, standing fence, I then, on this foundation, lay three or four more rails, according to their thickness; if a meadow or inside, one or two, fitting them neatly in their lap between the stakes, with an axe, so as to have the stakes to touch each rail if I can. I then begin again at my first joint, and with a rope noosed at one end, throw it over the top, and draw the stakes tight together, and adjust the joint properly; then with an inch or larger auger, bore another hole straight through the middle of the stakes as they stand, so as to touch the top rail; here another pin is driven, which must have a head at one end, and be fastened at the other with a light nail, set a little into the outside of the stake; take off the rope when the joint is thus firmly pinned up, and thus go over the whole; when you may put above this pin just as many more rails as you please; and, if it suits you, put in a third pin on the top, or one rail below the top, which will both strengthen your fence, and prevent a mischievous beast from lifting it. A joint with three pins, not set in the ground or railed, has this aspect; the proportions between the pins being as three to two feet apart; after the fence is made, the sharp ends of the pins should be cut off, to prevent mischief.



The labor of making the improved fence, when equally familiarized to the mode, is less, at *first setting*, than cutting and splitting trunnels, and procuring the mass of timber required by the worm. To say nothing of its better appearance, I will state only the following advantages.

1st. *Saving of land.*—A worm fence requires from five to six feet in width from the foot of each outer stake; the improved fence, only the thickness of the rails, say five to eight inches. This will save acres in a large farm.

2d. *Saving of timber.*—A joint of this, (rails 11 ft. long,) reaches over ten feet from centre to centre: of the first, with a safe lap and the usual worm, quite one-eighth less; so that 100 pannels of the worm will make at least 112 to 114 of the improved fence, rating the same number of rails to each joint: but I find four good rails in a pannel to make an excellent fence against horses and neat cattle, thus saving the useless bottom rails of the worm. Trunnells also are saved, and as my fence never settles into the ground, the bottom rail of the old worm which generally comes out rotten, when new set, is always saved. I think I save more than one-third of my timber by this method.

3d. In the highest winds, I have never had a joint to blow down in the *improved;* this rates annually to the labor-saving account.

4th. In cases of *altering or moving*, the posts are taken up without unpinning, and the labor of setting them in another place is trifling.

5th. Hedges and trash, briars, &c. have no room for growth in the joints; mowing is easily performed under them, and stopping against very small pigs between the rails, is easily effected with a few poles of suitable length.

Its duration depends on the material used. I get cedar poles six or eight inches thick for the stakes—cut them in summer, when the bark slips easily, and lay them straight in heaps to season well, and I think they will last twenty years. Chestnut is perhaps better, and white oak and chestnut oak from heart logs are very durable.

Some may perhaps imagine, that this fence cannot be made with crooked rails; I have found by much practice, that I can use them better and confine them to their places better, than I can in a worm fence; straight and even rails, will make the handsomest, and perhaps the strongest fence in this, as in all others; but I think that any rails that will make other fences, may be used as advantageously in this.

Now, sir, you can, without the risk of offence, try a process of "combustion" with the above effusion; or give it to your readers, as may seem best to you.

Your ob't serv't, D. ALLINSON.

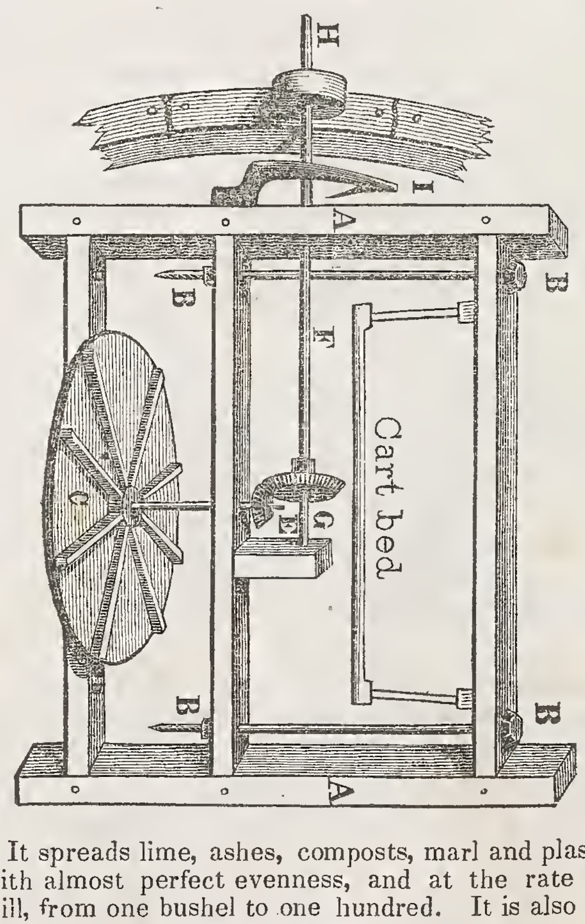
The Centrifugal Disseminator.

New-Brunswick, N. J. June 13, 1838.

J. Buel, Esq.—Sir—I observe, in the 2d number of this year's Cultivator, an inquiry of Samuel Howard, whether there is any mode of spreading lime, at the rate of twenty bushels an acre, other than that of doing it with the hands? Mr. Howard's inquiry is that of every enlightened farmer, anxiously engaged in improving the soil by top-dressings. Their difficulties are, the uncertainty of the quantity, the unequal distribution, and the very unpleasant labor attending the ordinary methods. I have sadly partaken of these difficulties, and it is therefore a matter of high satisfaction to me, that I am enabled to announce to the public the important fact, of the invention of an instrument that will not only remove the objections to the former methods, but enable us to effect the same improvement of land with a saving of at least twenty per cent of manure.

Within a few days, we have had an exhibition in the city of New-Brunswick, of an instrument that may be attached to either a wagon or a cart, patented by the name of the *Centrifugal Disseminator*, a diagram of which I send you, sufficiently perfect to give an idea of its principle.

[Fig. No. 47.]



It spreads lime, ashes, composts, marl and plaster, with almost perfect evenness, and at the rate you will, from one bushel to one hundred. It is also calculated to sow grain and grass seed.

A company in this city purchased the patent right for the counties of Bergen, Passaic, Essex, Morris, Warren, Sussex, Somerset, Hunterdon and Middlesex, of this state; and have appointed Joseph Castner, (carriage-maker of this place,) as their agent, to sell the right to counties or townships. He furnishes the machines complete with hoppers, at twenty-five dollars. Respectfully yours,

W. MYER.

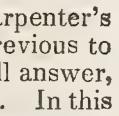
SPECIFICATION.

In order to enable a workman to construct one of my Centrifugal Disseminators, a frame, A, must be made of sufficient strength for the work required; and consists of two uprights, with two or more girts, placed horizontally, and secured to the cart by bolts and screws, B, the upper one of which rests on the top rails of the cart, the lower girts being under its bed, to support the shafts of the revolving platform, C, which may be about four feet diameter, made of sheet iron or boards, and has radiating cleats, to strengthen the platform, and give additional force to the distribution of materials; the lower pivot of the upright shafts which pass through the centre of the platform, rests on the lower girt, D; a horizontal driving shaft, F, is so placed, that a cog wheel, G, thereon, may work into a pinion, E, placed on the upright shaft, the upper part of which is steadied by the frame. On the outward end of the driving shaft, is placed a friction pulley, H, which is pressed against the periphery of the cart wheel, by means of a lever, I, attached to the frame, by the friction of which pulley, the revolving platform is made to disseminate whatever is placed thereon, when the cart is drawn by oxen, horses or other means.

Draining—Bad practices among Dutchess Farmers.

Judge Buel—Dear Sir—There is an article in the June number of the Cultivator, on the "best method of disposing of loose stones," by a correspondent in Ulster county. I think I can suggest a better "method" than the one he has adopted. There are on most farms, at least in this part of the state, wet spots, and springy places in hollows at the base of hills, and often in the middle of tillage lots and meadows, which it is difficult to cultivate to advantage on account of the coldness of the soil, occasioned by the superabundance of moisture, near the surface, and within the reach of the roots of the plants. Every practical farmer knows that the value of land is much lessened by the prevalence of such wet and cold places, besides the inconvenience of having in his fields every here and there a patch that is too wet to plough, or if ploughed and sown as is commonly done, nothing of consequence is ever reaped from them, because in the spring, or freezing and thawing weather, the grain or grass is sure to be thrown out, and of course dies. Now, to make such land dry and suitable for tillage, some means must be devised to get rid of the water, which is the cause of the evil. Draining must be resorted to in order to effect it.

The common practice is, and has been from time immemorial, to drain such wet places where the grain winters out as it is termed, to strike furrows promiscuously, so that the water may settle in those furrows and run off, so as to leave the surface partially dry. This is done after the rest of the field has been made as smooth as the harrow can make it. The practice I consider a bad one, and but a half way method of doing business. It renders the surface uneven and bad for the passage of the cart or wagon over it, and if designed for mowing, it mars that evenness of surface which constitutes the beauty and excellence of such lands, and which is the object of every good farmer to obtain, by the use of the harrow and the roller. Now, on all such wet places as above described, and which occur on almost every farm of a hundred acres in this country, I would dispose of my "loose stones" by digging trenches or drains, and filling them to within a foot or eighteen inches of the surface, so as to clear the plough. In this way, with little expense, two objects can be obtained, viz: the disposing of loose stone, and the freeing the earth of too much moisture; both of which are of the utmost importance in farming. I do not conceive that much art is necessary in forming underdrains of this description; all that is required, is to have them cut in the right places, and at the proper depths. The filling process is but a short job. I fill in this manner: take two of the longest and flattest, and set them on end with the bottoms apart so as to form a channel in the centre, with the tops leaning together, in this manner, and then fill in with others, so as to prevent them from falling. Shavings from the carpenter's shop I think the best to put on the stones previous to filling with earth; inverted sods or straw will answer, perhaps, where shavings cannot be obtained. In this way I have disposed of many loads of "loose stone," and intend to many more, having just made a beginning, enough however, to test the utility of the plan, and for the knowledge of which I own myself indebt-



ed to the columns of the Cultivator, which I have taken from the commencement.

There are many things practised by the good people of this country, which I should like to mention if it would be proper so to do; such as the neglect, by many able farmers, of their outside fences, by letting bushes, briars, weeds, and thistles grow along them; the irregularity of their division fences—laying out their lots in all manner of shapes—crooking this way to leave a piece of moist land in the meadow, (which by cutting a few trenches and filling them with small stone, might be converted into good and dry land for the plough,) and then that way, to get a patch of dry land into the plough land, &c. &c. Another error is, their leaving their barn yard full of manure through the summer, to be drenched by every shower, and exposed to the intense rays of the sun for two or three months; thus wasting and destroying in value, as well as in quantity, to say nothing of the inconvenience of getting ancle deep in filth, every time you have occasion to go to the barn. Another, which I think eqnally reprehensible, is the practice with many, of feeding hogs in the highway; to the total loss of all the manure they make or could be made from them, besides their liability to be run over by carriages and horses travelling the road. It oftimes requires considerable skill in the driver, to avoid being upset, or killing, or wounding a porker or two—for in riding past some rich farmers' door you will find in the summer season, perhaps a half dozen "mother pigs" with a host of young ones, quietly reposing in the middle of the street, totally regardless of the law which requires them to give half the road. If you keep the "even tenor of your way," you will be as like as not to maim, or disable for life, some one or more of the gentry, which is painful to a person of humanity, besides the anger which you are sure to incur of the owner. The best you can do in the case, is to waive your "right of way," and "pass by on the other side," and leave them undisturbed in their glory. I wish you could persuade these breeders of swine in the highway, to abandon the practice; don't you think it a bad one?

Yours respectfully, P****.

Clinton, Dutchess co. July 4, 1838.

Why are our Dutchess correspondents shy of giving their real signatures? Not certainly because they are deficient in practical knowledge. The very date, *Dutchess,* is a passport to notice; but we are sure that the writer of the above would have lost nothing, while the public would have been gainers, by the substitution of *letters* for stars, in the above signature.

Successful Application of Lime in repelling the Grain-Worm.

J. Buel, Esq.—Dear Sir—As the least information relating to farming, may be interesting to those engaged in the business, I state, that Mr. Hardy Bundle, a respectable farmer of Greenville, in this county, informs me that last fall he sowed six acres of land with winter wheat, and fearing that the weevil might destroy his crop, he was induced to try the experiment of sowing slaked lime. He says, that while the wheat was in blossom, he sowed while the dew was on, all the field with slaked lime, except one corner, which corner the weevil have nearly destroyed; and that the remainder of the field is so heavy that he is now looking for sickles to reap it with.

Respectfully yours, C. SEELY.

Athens, July 25, 1838.

Renovation of old Meadows.

Winchester, Ct. 18*th July*, 1838.

Sir—I have a meadow which has remained undisturbed by the plough ten years; the grasses have degenerated, and it has become turf-bound, (if that is a proper expression; if not, it will probably give you my meaning.) It is a great object with me, and also with some of my neighbors, like situated, to regenerate the English grasses, and increase the quantity, without ploughing and re-seeding; as ploughing would produce a resurrection of small stone, which would cost $10 per acre to clear off. I have heard that meadows of this description might be benefitted by a sort of scarification of the sward. I shall feel indebted for any information which you can give me on this subject; whether there is any approved machine or instrument for this purpose, the best season of the year, and the *modus operandi.* I am young in the business of farming, and anxious to learn.

Very respectfully, your obedient servant,

W. S. HALABIRD.

Answer.—Top dress with 15 or 20 loads of barn-yard manure or compost to the acre—spread and sow grass seeds—immediately scarify with Concklin's Press Harrow; then bush the whole well, and sow plaster. Do this in the month of April. Ashes *may* answer as a top-dressing.—*Cond. Cult.*

The Silk Business—A Partner Wanted.

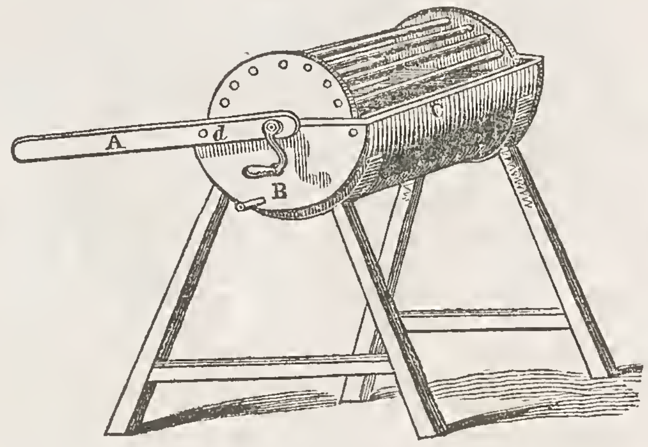
I have 1,800 morus multicaulis roots, with the growth, (most luxuriant,) of this year, for cutting and setting out next winter. I have any quantity of the morus nigra and alba, native mulberries. I have in progress of construction, a silk-house, 25 by 32 feet, 12 feet pitch, with a ventilator at top. My location is high and healthy, 60 miles north of Augusta, Ga. Land plenty and rich. This is to beg of you to make a contract with some man or woman acquainted with the business, to go and take charge of the whole affair for me, on the usual terms of joint copartners, in such business. I want to go into it largely if we find it advisable. My water power is improved and inexhaustible, and right at the spot; the soil suited by nature to the growth of the mulberry. The living is cheap and the country healthy. Rocks, granite and quartz—water, free stone. Yours truly,

J. W. D. WATKINS.

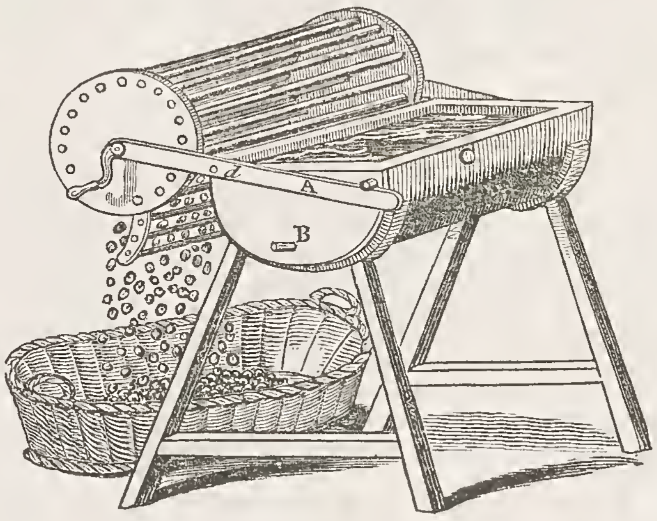
Potato Washer.

J. Buel, Esq.—Dear Sir—Having seen in your publication of July, a description of a potato washer, I beg leave to submit the following sketch to your inspection. It is intended to represent such an one as is used in some parts of England, where a great many potatoes are grown, both for the supply of London markets with the article itself, or indirectly in the shape of pork and beef; and for a cheap article for a farmer's use in this country, (the cost would not exceed $5, if so much,) would answer every purpose for potatoes and apples, if not for turnips.

[Fig. No. 48.]



[Fig. No. 49.]



The water tight cylinder, C, fig. 48 and 49, ought to be made about 6 inches larger in diameter than the inner one, which is made say 2 feet in diameter, with round bars of 1¼ inches, and with spaces of 1 inch between, and is hung on two moveable bars, A, Fig. 48, which when the cylinder is to be emptied of its contents, are to be turned over, as in fig. 49, on a pivot at each end at *d*, and a small door, formed by a few of the bars being fastened together with end pieces, hinged and hasped as is represented in fig. 48.

The hole B, is used for emptying the larger cylinder of water, (in which the filled small cylinder is turned, till the contents are sufficiently clean,) when too dirty for farther use. I am your well wisher,

Lockport, Aug. 1, 1838. J. E——D.

EXTRACTS.

On the Best mode of Applying Manure.

[It takes a long time to eradicate deep-rooted prejudice, or to change long established practices in husbandry, however inconsistent they may be shown to be, with sound sense and experience. The unreflecting or unenlightened farmer knows, that a certain process, to which he has been long accustomed, is likely to produce a given result. All beyond this is, with him, doubt and uncertainty; and he is extremely tenacious of old practices, lest any change should subject him to the charge of previous ignorance, or of copying after those who he is loth to admit are wiser than himself. It is to these considerations that we impute the reckless indifference which yet prevails in regard to the economy of manures. The old system was, not to regard this primary source of fertility; or, if applied to the soil, to allow at least a moiety of the value of it to be wasted by fermentation and exposure, before it was incorporated with the soil, or fed to his crops. The first innovators upon the old system, Young, Cooke, &c. aware of the strength of prejudice, and afraid of innovating too far at once upon old customs, ventured to recommend only a *partial* fermentation of yard dung, before it was applied to the soil; thus allowing a considerable waste of its fertilizing properties. The writer of the article inserted below, Mr. John Baker, of Nassau Cottage, Leeds, Eng. has had the courage to break through all the trammels of prejudice at once, and to apply his dung in its most recent state; and from an experience of twenty-five years, he has been able to demonstrate, from experiments upon a broad scale, that he doubles its value to his lands by the practice.

So far as a twenty years experience has enabled us to judge, unfermented dung, applied in the spring, spread broad-cast and buried in the soil, and to an autumn-ripening crop, either in the field or garden, has never failed (but once, in a protracted drought, applied to a ruta baga crop,) of proving beneficial—we think as highly so as an equal quantity of muck dung; while we feel confident, that by applying it in this state, we have doubled its intrinsic value, over what it would have been if it had summer-rotted in the yard. We cannot but indulge the hope, that the perusal of Mr. Baker's communication will induce some of our old fashioned farmers to adopt his plan, or at least so far as to test its utility.]

[*From the Edinburgh Quarterly Journal of Agriculture.*]

PARTICULAR MODE OF APPLYING FARM-YARD MANURE.

By John Baker, of Leeds.

"The present depressed state of agriculture through the kingdom, invites the serious attention of all connected with that important branch of industry; it being a lamentable fact that, whilst the most splended discoveries in science are daily applied to the improvement of our trade and commerce, agriculture, as a science, remains almost stationary, notwithstanding individual and national prosperity are so deeply interested in promoting its welfare. For more than twenty-five years I farmed from 500 to 1000 acres in the county of Norfolk, during which time my attention was carefully directed to the consideration of every method or system of farming which was calculated to increase the productiveness of the soil, and to improve the condition of that numerous and industrious class of persons who are dependent upon it. The proper use of manure is amongst the most material improvements which I have discovered. By the common, I may say general, mode of managing it, only half the benefit which ought to be conferred on the crops is given, whilst the system which I have adopted doubles the value of all the manure made, and at the same time it really lessens the expense; and it is to this point that I will confine myself in this paper. That "the muck-cart is the best farmer," is a maxim as fully acknowledged as it is oft-repeated, and believing that upon the proper use and application of it the success of the farmer mainly depends, I have never failed to attend to this important branch of husbandry. Having experienced the practical advantages of my system, as well upon land under my own cultivation in Norfolk, as upon farms belonging to my relations and friends in that county, where it had been introduced at my suggestion, I am induced, at the earnest recommendation of many gentlemen who have also witnessed its beneficial effects in Yorkshire, to invite the attention of agriculturists generally to the subject. Manure of almost every description is carried from the place where it is made and deposited on a heap for four, six, or eight months, where it ferments and becomes a soft, black, cohesive mass; it is then put on the land and ploughed down, after which the crop is sown; this may not always be done, but something resembling it is the prevailing and general practice in every part of the country. My method, the success of which have been proved by numerous experiments, is to spread the dung on the land as soon as convenient after it is made, except in winter; the manure made at that period of the year remains in the fold-yard till the spring, where it does not ferment. The whole is taken in the spring, summer, and autumn, fresh to the land; if in fallow, it is ploughed in with a thin furrow; the land is harrowed and ploughed again in a fortnight, and in a fortnight after, harrowed and ploughed a third time; after which the muck, however long it may have been, is reduced, and the soil will be in as fine and friable a state as the land is capable of. From the time the dung is put on to the last mentioned ploughing, nothing can be more unsightly than its appearance. If it is to be applied to pasture, I spread it over the surface of the ground from the beginning of spring to the end of autumn. Three essential points are to be observed: First, to apply the manure to the soil as soon as convenient after it is made (except in the depth of winter;) secondly, to keep it as near the surface as possible; and, thirdly, to mix it well with the soil.—These being observed, I confidently assert, that advantages equal to double those now derived from manure are communicated to the land by an increase in the fertility of the soil, exhibited in healthier and more abundant crops; so that a farm of 200 acres of arable land of medium quality, producing 400 loads of dung, or two loads for every acre, worth five shillings per load, will be benefitted to the extent of ten shillings per acre annually, and where more manure is made, which on every well managed farm is done, the advantages will be greater. This result has been produced upon the farm now in my occupation, belonging to Lord Cowper, in the neighbourhood of Leeds, to which I entered at Candlemas 1831; it was then in the most deplorable condition; so deplorable was it, indeed, as to lead many of my friends and neighbours to predict the impossibility of my procuring a tolerable crop upon one of the fields for seven years to come; but this field, from the application of manure according to my method, has become exceedingly productive. I fallowed it for turnips, and in May (1831,) I put on about twelve and a half tons of good fresh made stable-dung per acre; as much as possible was taken from the stables and carried to the land the day it was made. My proceedings greatly amused my agricultural neighbors. The preceding tenant observed, that however such a system might have answered in other parts of the country, here it would be a useless expenditure both of time and money, and a great waste of manure. To convince him of the benefit to be derived from such manuring, I directed one piece in the middle of the field to be left without covering. With the exception of the land upon which no manure had been laid, the field produced a very fine crop of turnips, worth at least six pounds per acre, whilst the crop raised upon the land not manured was not worth six shillings per acre. After the turnips, the field produced a very heavy crop of barley, averaging not less than seven quarters per acre, and in 1833 I obtained a most abundant crop of clover without any manure except on the land omitted in the first year. I also covered a field of pasture the same summer with the same kind of manure, half of it in June and the rest in August. Six weeks after the first part was done, I shewed it to a very shrewd and scientific gentleman, well acquainted with country affairs, who expressed his astonishment at the improvement. In October, the farmer whose land adjoins my own, said he had never before seen such extraordinary improvement in any ground. Knowing that he was one of those who had ridiculed my system, I hinted to him that the propriety of it had been much doubted. He acknowledged he had condemned it, and said he now saw that which he would not have believed had he not witnessed it, and that he thought the manure must have contained a large portion of white clover and other grass seeds, otherwise, in his opinion, such an effect could not have been produced. In the hottest part of last summer, I covered, in the same manner, the only field on my farm which had not been previously dressed in a similar way, leaving two ridges in the middle unmanured. I removed all the cattle from this field for six weeks, at the end of which the two ridges had scarcely grass to sustain a goose, whilst the rest of the field looked like a field of fog or aftermath. Many gentlemen examined it. Some seemed satisfied that much benefit was derived at very little cost; others expressed their conviction that it was the greatest improvement they had ever seen, and it is my firm belief that, from the time the dung was put on, to the end of summer, I had at least three times as much grass from the land manured as from the other. I must mention another fact. The man who spread the dung had farmed many years for himself, and might be considered a clever man; he said to me, you would not thus waste manure if you had not the means of getting plenty more. I asked him to wait a month before he decided; he then declared that he had never been so much mistaken. I mention these things, knowing that my plan has much to contend against, and hoping that noblemen and gentlemen, who try my method, may not be laughed out of it before they have applied to it the test of due experience. It may be said that, in these experiments, I did not compare different sorts of manure. I have done so repeatedly, but, in truth, I had then no rotten dung by me. I would propose, to any one who doubts the propriety of my plan, to put a given weight of fresh dung on a heap, to remain (turning it over or not) for twelve months, at which time spread it over the land, and at the same time take a similar weight of fresh dung of the same kind, and spread it over double the space, and I doubt not the result. Hitherto I have confined the recommendation of my plan to practical experience alone, but I am not without scientific and chemical authorities to support me. Mr. Joseph Hayward's Treatise on the Science of Agriculture is worth reading by the agriculturist who searches after truth. Being aware of the great difficulties with which the farmer has to contend, I should recommend any new system with great diffidence, if attended with additional expense; but as the plan I am desirous to introduce is alike recommended by its simplicity and economy, and also eminently calculated to promote the fertility of the soil, and to secure, by that means, a more adequate remuneration to the farmer, I cannot doubt of its being generally adopted, whenever its practical advantages are more generally known and appreciated. My subject has drawn me on to greater length than I expected; I cannot, however, conclude without saying, that if, by the system I recommend, 10*s.* or 15*s.* worth of manure can be added annually to every acre of land of moderate quality, at no greater expense than by the old method, I think the landlord, the tenant, and the public, will be great gainers."

On Education.

[*From the Educator.*]

To *educate* signifies, literally to *draw out*—to *lead out;* and implies something within—something concealed, covered over and not to be immediately accessible for present use; but which, by a little careful management and a right use of means, may be led forth from its retirement, and thus become available. Thus the decaying vegetable matter which lies lifeless in the soil, by proper means may be drawn up into the roots and branches of a seedling tree, and finally become apples, pears and peaches; or into the stalks and heads of wheat, and so become bread. Thus by educating the plants of his field, the farmer feeds the world. The steps of his process are immensely various, but they are all connected with the one grand design, viz. the *drawing out* of the earth what lies hid in it. Now it is obvious that he works entirely by the agencies of nature. He cannot make a blade of grass grow on a grain of wheat. It it the Creator's power, operating according to the laws which he has established in his world. And the farmer *leads out* the plants and the trees which feed the race of men, just by using skilfully the agencies of nature. His whole skill lies in just giving his tree or his wheat *food* and *protection*—every opportunity, and no hindrance, in the way of their expanding their powers. He cannot force them.

Thus also with his domestic animals; all he can do to *draw out* their powers and properties is just to afford them protection—defence against themselves, against one another, against the inclemencies of time and season; and food suited to their innate powers and capacities, and that in proper measure and season. For an animal, like a plant, may be injured by excessive or untimely food and drink. If it be the strength of the ox or the horse that is desired, this quality can be *drawn out* most efficiently by a careful observance of the laws of his nature. He must be gradually trained to its exertion, and the less violence he suffers, the more strength will he expend in his master's service.

So also is it with the powers of man. Infant human beings are the germs whose development is the business of the educator. Feeble plants, indeed! needing above all others, and for a longer period, the hand of protection and of sustenance! But it is with these as it is, generally, in the vegetable kingdom: plants and trees of rapid growth are short-lived.—The Lombardy Poplar soon outstrips the Cedar, but i's age is as nothing compared with it. Animals too are somewhat analagous. And in our own nature, the animal frame of rapid growth is not generally robust.

In contemplating infant humanity as the subject of this process of *drawing out*, three classes of powers seem to comprehend the whole nature, viz. the *animal* or *physical;* the *rational* or *intellectual;* and the *religious* or *moral.* To us it appears that under one or other of these may be arranged all the powers, properties, or faculties of our nature, the *leading out* and perfecting of which is the high and noble object of Education. Let us glance at these in their order.

Physical Education first claims our attention. Because, for a long period of time,—a period equal to that in which most animals come to full maturity,—man is to us, an animal only. He is thrown upon our care absolutely helpless; and our first concern is to protect him and to apply such means as are adapted to put into action the powers he possesses.—Warmth and food are his chief wants. These administered in due proportion, and in proper season, will keep his feeble powers in action, and by their action they increase their own strength. The importance of paying strict attention to the bodies of infants, youth and men, it is not difficult to see. True, the body is of small moment in comparison with the mind: but it is equally obvious that it is to us the vestibule of the soul—the door of entrance to the rational mind. Our success in preserving the body in life and health, is indispensable to our introduction to the mind. We can operate upon this only through that, and the existence and healthful action of the one is indispensable to the growth and expansion, *under our influence*, of the other.

Here then opens out before the educator, an almost interminable field; and one too, of a very inciting character. Even in this lowest department of his labors, where he has to do with matter and its modifications, he occupies high ground. For the matter with which he is conversant is organized, and that in the highest degree known to us—so organized as to come into immediate union with spirit. Of all material subjects, the human body, mysteriously connected with an immortal mind, and destined to be connected in an endless duration, is surely the most interesting and the most important. We consider then education as including the entire business of protecting, nourishing, training and governing the body for the perfecting of its powers. Of course the more accurate knowledge the educator has of it, the more likely is he to succeed in his efforts. And we hope to see the day when mothers, to whom the business of education must first of all be entrusted, will themselves be instructed in the general principles of anatomy and physiology; that understanding the nature of the trust committed to them, they may be prepared the better to discharge its duties. And we hope to enrich our own columns occasionally with articles original and selected on all the various topics that relate to the healing art, and especially the art of preventing injuries to the human frame. *A sound body will always have in it a sound mind.*

Under this department also is to be ranked the whole subject of the animal passions, appetites and desires. Every thing therefore that adds to their proper restraint and direction—every thing that goes to explain their connexion with their body on the one hand and the mind on the other, falls within our province here.

But Intellectual Development is the chief part of education—rather, it has so been viewed by mankind. And we are ready to admit that in comparison with the preceding it is chief. Nor is the general principle different here. The powers of the mind are to be awakened, as it were, like the powers of the body, by the application of suitable instruments.—Food is an instrument for awaking and strengthening the powers of the body; knowledge is the food of the mind, by which its slumbering powers are awakened to energetic action, and by which its *dead powers*, to use a contradictory phrase, become living energies. And the resemblance holds to a very beautiful extent between them. Give strong meat to children and you injure their health; give abstruse and difficult knowledge to a feeble mind, and you overwhelm it; it becomes feeble and sickly. But let the items of knowledge be always adapted to the capacity of the learner; still a little beyond his last attainment; just so far as to induce effort, and not to produce discouragement; thus you carry him onward in the endless race.

Now there is one thing we wish to be distinctly understood between us and our patrons in this matter. It is this; knowledge is not the ultimate object in education. It is a means to an end yet beyond it. The end which we shall still hold up as that at which the Educator aims, is the perfecting of the human being. The efforts of mind which we make in the attainment of knowledge, strengthen it and produce habits of systematic and persevering action: and this increase of the power of the mind is the chief gain. It is not the youth who has acquired at school the most knowledge, perhaps, who has received the most benefit. He may have acquired it as the tub at the pump-spout acquires water; what has been pumped in may be pumped out again. But the youth who has been taught to exercise his own power in the acquisition of knowledge; who has wrought it out for himself, with only the direction of his teacher; this youth, though he may have a smaller amount of knowledge than the other, yet has an inexhaustible supply. His is not a tub, but a spring, flowing up from its deep and exhaustless source. The man has made his capital and his ability to use it; the other has fallen upon his by some gambling turn, which threw the product of other men's labors into his hands. The one will wear and the other will wear out. We will never advocate hydraulic force pumps to create stagnant pools of knowledge, whose possessor knows not how to use. Rather let us remove the tall grass in the ravine on the mountain side, and the turf and the leaves, and open up and lead forth the purling stream, whose limpid waters sparkle as they pitch down the precipice and hasten on to swell the waiting brook below.

One other remark on intellectual education. It is interminable—absolutely interminable. That is, the enlargement of the intellectual powers, by their own legitimate exercise, continues through life. It does not stop when a boy leaves the school; that is, if he has been rightly trained: if he has been educated at all. If indeed he be a tub, pumped full, of course he can hold no more. But if his powers have been awakened; if he be a spring from the deep mines of knowledge, then he will continue to flow on for ever.—Through life he is still improving; and after the body shall have ceased to be the vehicle of thought, no doubt the mind will continue to expand in knowledge and perfection for ever.

This suggests our third general branch, MORAL EDUCATION; and the first remark we have here is, that the two preceding will prove a curse or a blessing; an injury or a benefit to the individual or society, just as this last is successfully attended to or not. Every man must see that great physical powers and great intellectual vigor, if not under the wholesome restraints, and government of sound moral principles, must do great mischief. The more power a wicked man has, the more dangerous is he. A man who cannot engrave, is unable to produce counterfeit bank notes; and a man who cannot write at all cannot sign them. Better far for the forger and for society, that he had never learned to write, or even to read. Morality is to education what the compass and helm are to the steam ship. The hugeness of her mass, and the might of her motive power, are the measure of her capacity for working ruin, if that might and mass are ungovernable. But put man's physical strength and his intellectual force under the proper command of a *moral helm*, and neither can ever become too great for safety.

Another remark it is well here to throw out. We do not place moral education third because of its inferiority, nor because of its entire subsequence in order of time; but because the others must precede it in part. Physical education necessarily begins first; then the intellectual, then moral; but they run together from a very early age. They are to a large extent mutually dependent, for every teacher knows how much more successful his labors are with youth whose moral principle, like the fly wheel of a powerful engine, regulates his movements. Sole attention to physical education may produce mammoth strength, but it is mere brute mass. Sole attention to intellectual education may produce monster fiends, with immense heads and no heart. Sole attention to moral education is impossible; for the examination of moral truths calls for the exercise of intellectual power; and therefore this department includes both the others.

Again, morality, as distinct from religion, we do not know. Believing ourselves, that there is no boundary marked out by the Creator between them, we shall not attempt to force nature in violation of her own laws. With Washington, we would ask, "Can it be, that Providence has not connected the permanent felicity of a nation with its virtue?" "And let us with caution indulge the supposition, that morality can be maintained without religion." This moral training begins almost in the cradle, and ends—we were just about to say, at the grave; but no. It never ends. We must think the moral faculties, like the intellectual, capable of interminable expansion.

Now, for the development of the moral powers, the moral government of the family, the school, the state, or the church, are chiefly instrumental. And being Christians, we suppose the sum of all the great principles of moral government is contained in the sacred Scriptures. The general truths, therefore, of the Bible are highly important and indispensable to the highest success of education. No system that excludes the fear and reverence which the immortal mind owes its Maker, can be fully available for the development of its more elevated moral attributes. But whilst we consider the successful educator as under imperious obligations to use the Christian Scriptures as an indispensible auxiliary, yet, being ourselves of different sects, we are perfectly clear, that the narrow spirit which sees excellence only within the precincts of sect, is utterly unworthy of the broad foundations on which popular education should rest. The Educator then, will occupy only general ground in the department of morals. It stands committed to the common Christianity and the morality of the Bible, and will treat of these only so far as may be necessary to the public virtue, and to show, as Washington says, that "reason and experience both forbid us to expect that natural morality can prevail in exclusion of religious principle."

Relative value of Manures.

[*From the Genesee Farmer.*]

Since the great truth in agriculture, that manure forms the basis of all successful farming, has been more fully developed and better understood, the attention of agriculturists in foreign countries and in this, has been directed to the discovery of the most efficient articles for this purpose, and the best methods of applying them. So convinced have scientific, as well as practical men, on this point, become, that on their representations, the government of several European countries have ordered extensive investigations to be made, and experiments carefully instituted, to determine several questions relating to manures, upon which farmers and experimentalists were not entirely agreed.

The Prussian government, which, in every thing relating to the welfare of the people, in giving them every advantage of education, and the benefit of every improvement in agriculture, has evidently taken the lead, and in conjunction with the Saxon authorities, appointed Professor Hembstadt, of Berlin, to superintend a series of experiments, and publish the results for the use of the public. The effect which the application of night soil and urine had produced on the agriculture of Flanders, where they had been most extensively used, induced the governments of Berlin and Dresden to place under the directions of the Professor, the contents of the city drains and cesspools, for the purpose of attempting the recovery of the barren and light soils in the neighborhood of those cities. Thus countenanced, that eminent agriculturist, in conjunction with other learned men and practical farmers, commenced a series of experiments, which were carried on for a number of years, and varied in every possible way, in order to avoid all sources of fallacy. The results of the experiments have been published by Hembstadt, and have led to extensive and successful agricultural improvements.

Professor Schubler, the writer of the most esteemed, and certainly the most able, Treatise on Agronomia, or the best method of knowing and treating every species of land, since the death of Hembstadt, has repeated and added to the experiments of that professor, obtaining the like results in almost every instance. These he has published in a tabular form, which have since passed into the hands of all the large practical farmers of Germany, and have formed the basis of instruction on manuring, in the hands of professors of agriculture, whom many of the continental governments have with great advantage established in institutions purposely formed to disseminate useful and practical truths in the art of farming. From these tables Dr. Granville, in his report to the Thames Improvement Company, in speaking of the immense source of agricultural wealth which the sewers of London afford, but which is now worse than lost, makes the following statement of facts furnished by them.

If a given quantity of land sown, and without manure, yields three times the seed employed; then the same quantity of land will produce—

5 times the quantity sown, when manured with old herbage, putrid grass or leaves, garden stuff, &c.
7 times when manured with cow dung,
9 times with pigeon's dung,
10 times with horse dung,
12 times with urine,
12 times with goat's dung,
12 times with sheep's dung, and
14 times with night soil, or bullock's blood. Or in other words, an acre of land sown with two bushels of wheat, without manure, will produce—

6	bushels,	
10	"	with vegetable manures,
14	"	with cow dung,
18	"	with pigeon's dung,
20	"	with horse dung,
24	"	with goat's dung,
24	"	with urine,
24	"	with sheep's dung, and
28	"	with night soil, or bullock's blood.

But if the land be of such quality as to produce, without manure, 5 times the sown quantity, then the horse dung will yield 14, and the night soil 19⅔ the sown quantity; or land that will yield without manure 10 bushels an acre, manured with horse dung will produce 28, and with night soil about 39 bushels of wheat per acre.

These results, and multitudes of recorded experiments prove that they in no case vary far from the facts, show the immense superiority of night soil, or Flemish manure, over any hitherto employed. In addition, Dr. Granville found that some crops which yield large profits, and are so extensively cultivated in both Flanders, can only be obtained in abundance, and of the finest quality, by employing what may emphatically be termed Flemish manure in the preparation of the soil.

Another important matter in the comparative value of manures, and of essential practical interest to the farmer, has been established by the same authoritive investigations; and that is, that while night soil has produced fourteen times the quantity sown, where horse dung has yielded only ten—the proportion of the former, or Flemish manure, was, to the horse dung employed, only as 1 to 5; so that with one ton of the Flemish, a larger produce was obtained than with five tons of the best stable manure.

Dr. Granville has drawn some valuable inferences from these truths.

"In England a ton of good stable manure sells for five shillings. Now an acre of arable land in an ordinary state of cultivation in England, is manured with 20 tons of horse or stable manure every 4th year, according to Professor Coventry, and consequently entails an expenditure of £5 in that year. It then produces ten times the quantity of wheat sown. But an acre of the same land similarly sown, and manured with Flemish manure, would require only four tons of it, and which at the price we have fixed for it, (12 shillings a ton) would be an expense of £2 8s. It would then produce fourteen times the quantity of wheat sown on the acre. Supposing the produce of the acre manured with horse manure to be 5 quarters of wheat, and to sell for £15, that of the acre manured with Flemish manure, will be seven quarters, and sell for £21. The result of this comparative farming operation, therefore, would be;

1st, a saving in manure of £2 12*s*. per acre.
2d, a surplus produce of 6 00 per acre in money.

Total in favor of night soil, £8 12*s*. per acre.

"Dr. Granville states, that he was assured by Mr. Smet, a great farmer in East Flanders, that a measure of wheat land corresponding to an Englsh acre, manured with Flemish manure, produced last year 7½ sacks of wheat of the best quality. The sack contains four measures, each weighing 180 pounds of 16 oz. each; consequently there grew upon the acre 5,400 pounds of wheat, or 90 bushels."

The heaviest crop of wheat we have ever known produced in this country, was the one for which Mr. Blackmore, of this county, received the premium, 64 bushels per acre. The capabilities of the soil, therefore, when put in the best condition, is little understood, or the amount of food an acre can produce, not generally known. The *science* of agriculture is yet in its infancy, however venerable and ancient the *practice* may be; and perhaps in no branch of it is our knowledge more defective than in that relating to manures.

Professor Johnson's Lectures on Botany.

[*From the Farmers' Magazine.*]

After recapitulating some of the topics of the preceding lectures upon the development of vegetation, the learned Professor commenced with remarks upon the grasses. These grow in all parts of the world promiscuously, and without cultivation, and being the principal nutriment of man, their cultivation follows him in society and his migrations. The Mogul and Caucasian races of men subsist upon wheat and barley; while rice and millet form the food of the Negro and Malay, and the tribes of ancient Mexico were bounded by the cultivation of maize. The cultivation of the earth preceded the improvement of the intellect, and was the herald of civilization. It is remarkble, that we have no direct criterion of the origin of many of those grasses met with everywhere in cultivation, as none of them are to any extent found wild. Some travellers have thought that barley was indigenous to Tartary, rye to Creta, and wheat to Asia; but these might have been diffused from some cultivated some years previously. Corn is not only the support of man, but the grasses are the subsistence of the animals which form his nutriment. The nutritive quality of grasses, is principally owing to the sugar which they contain, and of which some English grasses contain large quantities, but the sugar cane is the only grass that is exclusively cultivated for obtaining this article for commerce. The grasses are applied to a vast variety of important mechanical purposes; they are found in every part of the world, from the Poles to the Equator; on the land, as well as floating on the water, and are the universal food of animals. It has been estimated that the daily consumption of corn in England and Ireland, is, 1,238,096 bushels of wheat and barley; besides annually, 100,000 bags of rice, and 450,000,000 lbs. of sugar. Besides these may be estimated as the immediate products of the grasses, which consumed by animals forms the food of man, a quantity of almost inconceivable amount. In London alone, is annually consumed 155,000,000 lbs. of butcher's meat. Of cheese, another production of grass, 11,500 tons are annually introduced into London, from Cheshire, about 20,000 tons from Warwickshire, besides that from several other countries. Of butter, the annual consumption is almost 50,000,000 lbs. the produce of 300,000 cows; and in London, between 9 and 10,000 cows are kept for the supply of milk to the inhabitants, which produce an annual supply of about 30,000 millions of quarts. All these are the immediate products of the grasses.

Most culinary vegetables belong to the cruciform, umbellate, or papilionaceous varieties of plants.—The first is so named from four petals forming the flower, being disposed in the form of a cross, as in the wallflower. It may be remarked, that not a single species included in this group is poisonous, but that the whole, if not absolutely employed as food, are not deleterious. The cabbage, cauliflower, brocoli, sea kale, turnip, mustard, and almost all culinary vegetables, but spinach, belong to it. Another extensive group, is the umbellifera, so called from the arrangement in umbels, the main flower stalk diverging into a number of spokes like an umbrella. Although this class contains many used as condiment or food, many others which are very poisonous, are associated with them, as the hemlock. We know too little of the natural affinities of plants, to enable us to distinguish the poisonous, from those that are not so; as the sweet chervil of the garden, which is often mistaken for hemlock, nor the common celery, mistaken for the same. Accidents from this kind are not uncommon, and it was from eating drop-wort that grows upon the banks of the Thames and other rivers, instead of celery, that several convicts died at Woolwich, three or four years ago. The papilionaceous, include many used for food, as pulse, beans, peas, tares, saintfoin, and others, and are so named from the fancied resemblance of the flower to a butterfly. The fruit forms a pod, called a legume, and the plants are therefore called leguminous; of many of them, the seeds are food for man, and the stem and leaves of some, are food for cattle; but the seeds of the alburnum, and many others, are poisonous. Although we are not yet sufficiently acquainted with the characters which may enable us to distinguish the qualities of all, yet, De Candolle has furnished us with a sign by which we may in some measure distinguish betwixt those which are poisonous or not. It is by observing how the leaves spring from the seed, which are found to be very dissimilar. Some throw their lobes above the ground, and are of a green colour, as in the laburnum. In most of this kind of plants cultivated for the purposes of food, the leaves remain beneath the soil; but although this cannot be taken as an absolute criterion of a wholesome plant, from the circumstance that some of them throw up their leaves, it is a well recognized fact that no poisonous plant keeps its leaves beneath the surface. The potato is a member of a poisonous and narcotic order, being included in the same as the hemlock, nightshade, and mandrake. The potato being wholesome, seems to mark another feature, that some parts alone are poisonous whilst others are not, and that this poisonous principle may reside in different parts of the plant. In the poppy, the seeds are not poisonous, but on the contrary, highly nutritious; in some parts of the continent being a food both for man and animals. It is used extensively for the adulteration of oil; a large portion of the olive oil imported from France being almost exclusively composed of it. The fleshy part of the plum and other fruits is good for food, and nutritious, whilst the kernels and leaves are highly poisonous, containing hydrocyanic acid. The tubers of potatoes when roasted, are good, but the stem, leaves and other parts of the plant are deleterious. The tubers, when on the ground and exposed to the surface of light, become green, and taste badly. In its history the potato presents the same hemisphere as various kinds of corn. It was not known in the Eastern hemisphere, or the Old World, until after the discovery of America, where it was found cultivated in Peru, from whence it was introduced by Sir Walter Raleigh into Virginia, in 1586. It is supposed to be indigenous to the Andes and Peru, but it is not found there in a wild state by travellers. In many parts of Asia Minor, the soil is covered with the citron, cherry, pear, and other varieties of fruits. Although we are ignorant of their native spot, they may have formerly been introduced into these parts and cultivated, and point out ancient civilization. Many ages ago, science and civilization were confined to certain parts; and from countries in proximity to the Euxine Sea, the gulph of Persia, and other parts, was Europe indebted for its supply of almost all descriptions of fruit and vegetables. In the time of Cato, the Romans were neither acquainted with peaches or mulberries; in that of first Tarquin, the olive was not known to exist in Italy, Spain or Africa; in that of Appius Claudius, olive oil was rare; but now, all the neighboring countries derive their supply from these parts. In the time of Pliny, it was introduced into France and Spain. The vine, all the varieties of which originally sprung from one species, modified by climate and cultivation, is interesting in its genealogy. It was not known originally in Europe, but followed man in his migrations. It is found wild in the Caspian, though we have no reason to suppose it originally to have been so.—From Greece it was introduced to Sicily; by the Phoceans it was carried into the south of France; by the Romans to the banks of the Rhine; from whence it was extended to the various islands of the Mediterranean. Several of the fruits so important in the tropical regions, as the banana, the date, cocoa-nut, &c. have the history of their origin involved in the same obscurity as the European plants just named.

The solid matter of which vegetable substances are principally supplied from the earth, is carbon or charcoal, which principally comes through water. In plants growing in the arid sands of tropical regions, which are scarcely susceptible of supporting vegetation, we find very little carbonaceous matters, a small proportion of the solid principle being combined with a large quantity of aqueous juices. There are certain other principles which must be furnished from the soil; and if it be destitute of these, the plant cannot be fostered, and hence the difficulty of cultivation, from not knowing the chemical nature of the earth and soil. Plants growing in the neighborhood of the ocean, contain soda, which has its origin in the spray of the sea to which they are exposed; the common eryngo will grow in such situations, but not in a garden, from the want of sea-salt. It has, however, been kept alive under such circumstances, by watering with water in which sea-salt had been dissolved. The matter of flint, or silica, is contained in considerable quantities in many plants, as in the common cane; if two pieces be rubbed together they will produce a light from this circumstance.. When we examine the cuticle, we find a considerable quantity of minute flinty matter, which produces the light. Mechanics are in the habit of using a vegetable production called Dutch rush, but which is not common in this country; it is used by cabinet-makers and workers of brass, for polishing, where it acts like a fine file, caused by an innumerable number of peices of rock crystal. Two causes may be assigned for the presence of this:—it is either imbibed by the plant in a fluid state, or produced by a certain specific vital action in the plant. As we do not know any instance of the latter, the former may be assigned as the probable cause. Such plants will not grow without silica, and in situations where plants do not flourish, it is owing to the circumstance, that the soil does not contain its proper quantity of proper earth.

Lime is a well known substance, existing in vegetables in various proportions; in some being contained in a considerable quantity. It is always in combination with an acid, either the carbonic or the phosphoric, analagous to chalk or animal bone. One probable cause of the fertility of lime, when applied as manure to soil, is in the carbonic acid which it absorbs from the atmosphere, presenting it in a form by which it is readily decomposed. The soils which contain lime are most favorable for the growth of corn; and wheat never flourishes more than where it abounds. It is contained in grain in such quantities, that it is computed that every person who consumes 1 lb. of bread daily, will, in the course of one year take into his system 3 lb. 6 oz. 3 drachms, and 44 grains of phosphate of lime. This circumstance is the reason why it is of superior quality over other grain, as it forms the principal part of human bodies. It is found in milk, where nature seems to indicate that it is contained for the nourishment of the young animal, from the remarkble fact that when they are able to take other food, the milk loses its proportion of this substance. Although phosphate of lime is contained in considerable quantities in the adult secretions, it is not known in those of the young, being all taken up for the purpose of nutriment. The shells of eggs are formed of this substance, and Dr. Paris has ascertained the singular fact, that if the legs of a hen be broken, she will lay her eggs without shells until these are repaired, for which the lime is required. Hens will also lay their eggs without shells if there is a deficiency of lime in the yard in which they roam. It is a remarkable circumstance, that although the grain contains the phosphate, the straw contains the carbonate of lime. Carbon is, next to water, the principal support of vegetation. In the formation of soil, the earthy and crustaceous lichens are planted first: these die and form a bed for the seed of the mosses. In the fertilization of land, different operations are going on; the roots of the eryngo run five or six feet from the stem, they then die and form the vegetable matter or black mould which covers the barren rocks that cover the globe. Nature herself realizes the fable of the phœnix. Man, the lord of the earth, is subject to the same laws as all other created beings; furnishing after death food for others, as myriads have done before; and we trample on others alike in beauty and decay.

The Soil.

[*From the Educator.*]

By this term is meant whatever vegetables, plants, trees, &c. grow in. It may to the eye at least, be a collection of stones and rocks. It may be a bed of partially decomposed vegetable substance mixed with small portions of clay or sand—a bog. It may be an almost unmixed clay or sand. Still that substance, from the midst of which the plant thrusts itself forth, and where it grows, is its soil.

The use of the soil is threefold, First, it is the cradle and dwelling place of the embryo plant and its stay and foundation in after growth. It receives the seed and retains the roots of the tree and supports it. The solid parts of the soil constitute the pillars and props which uphold the growing plant. The same friendly office continues even after life has parted from the leaf and vigor of health died in the stem or trunk.

The second use of the soil is to furnish food for the plant. The first of all the ingredients necessary is moisture. The seed cannot expand and thrust into life the embryo tree or plant, without water. The absence of this universal solvent make all soils barren. Water is the universal *physical regenerator* of the vegetable world. Every seed was alive once; viz. when it grew on its native stem, whence it derived its being. The plant that bore it died. It died virtually itself—it exercises no living energy; but water—moisture, with that heat which it includes, penetrates its various parts and swells them into active life; it is regenerate to live, and henceforth, by the power of the same element, it continues to grow. What is the sap or juice of a plant, but water holding in solution in itself, various matters for the nourishment of the plant? Take away all the water out of a tree and can it live? The cedars of Lebanon and the pines of Alleghany, equally with the weeds of our gardens and the green moss that mantles the stagnant pool, are dependent upon water for their growth. Now the soil is a sponge full of water, ready to be applied to the parched lips of the plant it nourishes. This water is a *solvent*; that is, it dissolves in itself the various substances which go to form the body of the plant, just as sugar is dissolved in tea; and thus the water, which in the soil is a solvent, also becomes a *vehicle* to carry the food up the pores of the plant and to distribute it into all its parts; as in our mighty rivers and the great ocean itself, the water is the great transporter of all goods. The very power which calls the plant into life, continues its vivifying influence to sustain and carry on that life. Analogous to this, is the agency of water in animal life. Our bodies are equally dependent for their life, on the active agency of water. A similar analogy exists in regard to mind—there is a spiritual water.

But the *soil* not only *contains* this indispensable solvent; it also *consists* of various ingredients, which become mutual solvents. The different kinds of earths act upon each other, and, especially by the aid of water, act upon the vegetable matter mixed up with the soil, and so reduce it to that state in which it becomes the food of plants. Now it will be obvious, that the goodness of soil, must depend upon its capacity to *prop* up the plants, and to *supply* them with food. If they be well propped up and well supplied with good food, they must grow well: provided, they be not out of their latitude,

These remaks are intended to convince our agricultural readers, that an inquiry into the nature and use of soil, is not a useless speculation: nor is it a dry and uninteresting subject. Science lies at the basis of all art, and it is our wish to aid in lifting up terraculture to the dignity of a science. That is, we wish the farmer and gardener to understand the nature of their soil, and the laws of that nature, whose regular action produces the results at which he aims. We wish to see the cultivator not working blindfolded; but understandingly. We wish him to know not only that some kinds of soils are suited to some kinds of plants; but also why they are so suited—what it is in the soil which suits it to this or that particular vegetable production. For example, we would have the farmer not only to know the general fact, that lime spread on a field infested with sorrel will correct that evil, but also, why it will so operate. We would make the very labor of his hands, the means of enlarging the capacity, by stimulating the activity of his mind. We would have him a student of nature, on her most attractive pages, that his soul may expand indefinitely as it directs his bodily powers to the most profitable exercise.

The soil as a prop.—If you look at any plant you will find its roots are designated first to support it in its natural position. They spread round the stem, stalk, or trunk, in such manner as to stay it, like the bracing of a frame building. Now these braces must have a solid basis to rest on: less or more immediately contiguous to the stalk. Plants that rise high must run deep, or have wide spreading roots. The texture of the soil—whether stiff and tough clay; loose and open sand; moist and almost liquid marsh, or rocks with little minutely divided matter among them; the texture of the soil and the nature of the plant ought to be adapted to one another, and will determine the depth or width to which the roots will extend. In fibrous rooted plants, such as wheat, rye, oats, it is obvious that porous, open soils will afford the roots the best opportunity to run deep and wide. Whereas close, clay soils resist their passage, and confining their range, are unfriendly. Hence one way in which lime is profitable, is by changing the texture of clay lands. It combines with the clay, and causes the mass to granulate or assume the appearance of fine sand. So enabling the roots to spread and the air to penetrate the deeper into the soil. So whatever causes the soil to cake, to become stiff and glazed, as it were, on the top, must become injurious. Whether this is not an effect of anthracite coal ashes, remains to be decided. The small experiments I have made induce me toward this belief.

11th Annual Fair of the American Institute,

OF THE CITY OF NEW-YORK,

At Niblo's Garden, No. 576 Broadway.

This celebration of American industry and the arts will be opened to visitors on Monday, the 15th day of October next, at 10 o'clock A. M. Articles intended for competition for premiums must be delivered on Friday or Saturday previous, viz. the 12th or 13th of October. Choice productions from every department of industry, whether of agriculture, manufactures, or the arts, as well as all kinds of machines, models, &c. will be appropriate for exhibition and competition for premium.

To provide the requisite accommodations for the grand display which the notices already received decidedly indicate, Niblo's entire Garden has been engaged, embracing a part of the promenade, never before occupied by the Institute, with extra room one hundred feet in length and twenty-five in width. A powerful steam engine will be provided, which will afford a continued moving exhibition of machinery. The liberality of the public enabled the managers of the last two fairs to bestow in premiums, exclusive of diplomas, *sixty Gold Medals*, and *two hundred and sixty Silver Medals*, in addition to other not inconsiderable rewards in money.

Prompted by a desire to increase the interest awakened in agriculture, particularly in the culture of silk, a number of patriotic individuals have volunteered to add to the means of the present managers, in order to enable them to extend more liberal bounties, and promote among the silk culturists of our country a fresh spirit of emulation. This laudable example we hope the opulent and public spirited, who take an interest in other departments of productive industry, will follow by associating and contributing with similar high-minded motives.

The enthusiasm with which former celebrations have been hailed, and the cheering influences already inspired by the approaching one,—notwithstanding all our severe business calamities,—confer on them a character and value never before adequately appreciated. By means of these fairs, necessity, instead of depressing invention, has brought forth its mighty powers, and is developing its unbounded resources.

Articles sold during the fair cannot be delivered until the close: and in order to enlarge the amount of sales and bring to fabricators and producers immediate benefits, it is particularly desired that a description should accompany each article, stating the price, by whom manufactured, designating particularly the place where they may be obtained. The uses and objects of each article, if not apparent, should also be stated: such a description will facilitate the distribution of printed catalogues early in the first week of the fair, and will no doubt swell the amount of sales.

The public are invited to attend this anniversary celebration. Distinguished individuals, it is hoped, will be present, countenancing and inspiring as usual. Female delicacy, taste, and ingenuity, have never failed to impart a crowning effect; and we trust they will, on the coming occasion, more than ever command admiration.

MANAGERS.

Thaddeus B. Wakeman, Adoniram Chandler, Martin E. Thompson, Charles H. Hall, W. P. Dissosway, John Sampson, E. T. Backhouse, Timothy Dewey, E. D. Plimpton, Baldwin Gardner, James Hamilton, George Bacon, Joseph Titcomb, Jared L. Moore, John D. Ward, J. Van Norden, Frederick Goodell, H. M. Graham, J. On the Inflammatory Complaints of Farm-Horses.

By Mr. Matthew M. Milburn, Thorpfield, near Yorkshire.

Causes.—In order to clear our investigation of some difficulties, it will be necessary to show that there is not any peculiar predisposition to disease in the breeds of horses usually employed in heavy draught, nor to any particular and characteristic conformation of the animals, which, I think, can easily be done. The coach-horse and the draught-horse are now very frequently bred from the same mare, and the breeds are so completely crossed and intermixed, that further than form and capability, with a sufficient degree of blood in the case of the coach-horse, they have lost their distinctive breeds. The horses employed in the cultivation of light soils, which the introduction of turnip-culture has so much extended, has caused the coach-horse and draught-horse to assimilate very closely. The peculiar characteristics of the old Suffolk breed, is lost in the continual crosses which have taken place to obtain more speed, and the farm-horses generally, perhaps with the exception of those used on very heavy soils, are partaking much of the character of the coach-horses of some ten years ago, and although a lighter class of animals have of late years been held in requisition for light work, to suit the rapid communication which our commerce demands, still so much intermixture has taken place in the different breeds, that no distinction can be pointed out between the one and the other, in so far as liability to the diseases in question is concerned. We are not aware that any peculiar conformation has any connection with the predisposition to such diseases.—The horse required for fast-work must have a capacious chest, to admit of the rapid propulsion of the blood which his exertion demands; but the horse of heavy draught also is valuable for his depth and rotundity of chest, to enable him to perform the tremendous exertion which is occassionally required of him. There are two instances, however, where constitutional peculiarities may predispose to the complaints in question. There are certain horses denominated "*washy*," or horses in which the space between the last false rib and the hip-bone is wide; in the language of the jockey, when he is not "well ribbed home;" such are known to be liable to diseases of the bowels when put to extra exertion,—but upon what principle I am unable to say. Others have a natural or acquired habit of voracious feeding, which is extremely prejudicial to the healthy action of the digestive and excretory organs, and to which I shall presently allude.

The post-horse, and such as are required to perform fast-work, are more liable to attacks of diseases of the brain, the nerves, and the lungs, simply because their work consists of rapid powerful exertion;—the farm-horse,—the animal of long and steady exertion, to gripes, inflammation of the bowels, and stomach staggers,—results, as I shall presently shew of a management unsuited to the character of the labor we require from them. The stomach of the horse is remarkably small;—smaller in proportion to his size, and the quantity of food he requires, than any other domestic animal. Nature intends for him a supply of nutritious food, and that *at short intervals;* wherein he materially differs from the ox, whose capacious stomach will contain food which will not be digested for hours. The post-horse, the hunter, and the carriage-horse, have food of the most nutritious description, and the time during which they are worked is necessarily short, owing to the extreme exertion required; they return to their food, and although their appetite may for a time be impaired, and their stomach and bowels affected by the general debility of the system, yet they recover their tone, as soon as the rest of the frame admits of their taking food. The farmers' horse, on the contrary, has food of a less nourishing nature, his rack is filled with straw, or, at best with clover;—the ploughman rises early, gives him a feed of corn, and leads him to his work, where he continues for seven, eight, and even nine hours, and his whole day's work is completed before he is allowed to eat. We do not find the ox, worked under similar circumstances, so affected in the stomach and bowels, simply because his capacious stomach, when filled, requires many hours to empty, while, as we have seen, it is different with the horse. Debilitated and hungry, the horse returns, and his rack is plentifully supplied, and a good feed of corn given him, and he is left to himself; he eats voraciously, half masticates his food, loads his debilitated stomach, and his digestive organs are weakened, and permanently injured. This course is repeated,—a habit of voracity is acquired, and at no very remote period the food lodges and obstructs the pyloric orifice (the passage from the stomach to the bowels,) fermentation ensuses,—gas is evolved, the stomach distended; he grows sluggish and sleepy,—drops his head upon his manger; or he is delerious, and evinces that the sympathy which exists between the stomach and the brain has excited the latter organ; he rolls, paws, and is seized with convulsions; at length he expires, and he has died of stomach staggers. If the previous history of the horse is examined, it is probable that he has been subject to gripes: thus showing, not only the connection between the common management of farm-work horses and diseases of the organs of digestion and excretion, but between the two latter. The half-masticated food has irritated the bowels, extra exertion of the muscles has been required to propel the dung to the rectum, and cholic or cramp (spasms) of the bowels, has followed, or a course of continued irritation, or of continued cholic, or both, has ended an inflammation of the bowels. I remember a beautiful farm-horse, which, owing to the distance of part of the farm to which he belonged from the buildings, was worked the long hours described, and finished his day's work before his bait. He was constantly subject to attacks of the gripes, which was subdued; but he died of stomach staggers. The same stable, then so often subject to diseases, is now, by a change in the system, completely free from them. Another case, however, occured,—a beautiful compact little mare was constantly afflicted by cholic,—she eventually died of inflammation of the intestines.

There are other parts of the management to which horses employed in agriculture are subject, which induce diseases of the bowels; for instance, a boy returning from work, with heated and sweating horses, to save himself trouble, allows them to drink copiously at some pool or stream he passes. Suddenly one or more of the horses exhibit symptons of gripe, they suddenly lie down, roll about look at their sides, rise up, seem, relieved, and again speedily relapse; the sudden application of the cold water has produced spasms in the bowels, through which it has passed. This is neglected, or perhaps gin or whiskey, aided by pepper, is administered as a remedy, and severe and general inflammation of the bowels is the result; this is mistaken for another attack, and again the poison is administered, and the inflammation increased, and death follows. The horse of heavy work, too, is longer exposed to the inclemencies of the weather than the animal of light work. In the former, the rain is allowed to fall upon him for hours, and it is allowed *to dry upon his back*; the sympathy between the skin and the alimentary organs is known to every groom,—obstructed perspiration, and consequent irritability, is conveyed from the one to the other, and disease is the consequence. It is true, the latter is also partly exposed to the rain, but for shorter periods, and the wisp and brush are liberally applied when he enters the stable; a determination of blood takes place to the skin, perspiration is excited, and diseases thus prevented.

There is another disease to which horses are subject, and which is at once the cause and consequence of inflammation of the intestines. I mean intestinal calculi. Inflammatory action of the bowels, like that of every other part of the system which comes in contact with any foreign body, is liable to produce calculi, which in turn irritate the bowels, and produce a lasting predisposition to disease. For this I am not aware that any remedy has been discovered, and what is worse, they generally accumulate with age, and eventually produce death, the only power over them arising in our endeavors at prevention.

Prevention.—Of the best means of preventing these diseases in farm-horses we will now treat. We have attributed the peculiar liability to them in farm-horses to mismanagement, with the exception of certain instances of peculiar formation of the amimals, and although the farmer must necessarily work his horses longer hours than the horse of rapid work is capable, there is no necessity of depriving the animal so long of food. No horse should work more than five or six hours without a bait. If we examine the history of the stables of large farmers, whose fields necessarily lie at a great distance from the buildings, and where they are worked long in consequence, and compare it with that of small farmers, under the contrary circumstances, we shall find a striking difference as respects the health of the animals. The case referred to above strikingly illustrates the truth of this observation. But, it may be asked, how it is possible to bait the animals so far from home? The difficulty seems to be in procuring food upon the spot, for if this is not done, the precaution will be neglected, and, at any rate, the land will be occupied by it. This, however, may be remedied. In the case, for instance, of a field intended for turnips, which has to be worked during the spring, a part of it, half an acre, or in proportion to the size of the field, may be sown with winter-tares, a few of which may be mown off, and given to the animals green, without carrying them from the field, interfering with any crop, or wasting any time in carrying the horses to a distance. If the field be intended for summer-fallow the spring tare will answer, and which may be used in the same manner, instead of allowing the poor animals greedily and indiscriminately to crop the leaves of the hedges at every turning, from the impulse of hunger. There is another easy way of baiting, which some carters adopt, and which might be applied to the farmers' horse, especially when carting. It consists in securing a bag, containing corn, over the animal's mouth and nose, by a string, which passes over the poll, and is locally denominated a "nose-bag," or "horse-poke," and which should be removed when he has finished his feed. To prevent the effects of the wet upon the skin, an unexpensive glazed cloth may be thrown over the horses backs, and secured to the collar and traces. This may by some be considered very troublesome, but, it will be found, that when it is once begun, it will be considered no more trouble than carrying the rest of the harness, and if disease is prevented, the trouble amounts to nothing. To counteract as much as possible any habits of greedy feeding which the horse may have acquired, his corn should be mixed with chopped straw, or chopped clover, which will secure its proper mastication, and prevent many troublesome complaints, as well as render all the nutrition of the food available. These may be substituted by an admixture of clean chaff with corn, a plan which is pursued in a farm-stable with which I am acquainted, and is found a useful practice. It would save the animals much time in eating, if all their food was chopped, and perhaps steamed; but on this subject we have not sufficient data to determine it with accuracy.

CURE OF THE DISEASES.—The cure, it has been hinted, must generally be left to the veterinary practitioner in the complicated diseases of the horse; but I shall refer to the principles of cure, in order to guide the farmer from some errors into which he may otherwise possibly fall. To begin with the most difficult, stomach staggers, which is distinguished from mad staggers, by the sluggishness or dulness of the animal in the first stage of complaint; but from the sympathy between the stomach and brain, the former often ends in the symptoms of the latter. All the efforts of the practitioner must be to empty the stomach; it is often a fruitless attempt, but a powerful dose of castor-oil (1½ lb.) may be tried, as being rapid in its effects, and mollient to the hardened food in the stomach. Bleeding may also be useful in preventing the delirium. In the early stage of the disease, a stomach pump may be used to wash the food from the stomach; but here an experienced practitioner alone will be able to do it. Gripes or cholic are, fortunately, generally more easily subdued; they are distinguished from inflammation of the bowels by the suddenness of their attack, the temporary relief from pain, and the relief obtained from exercise, the symptoms of the latter being directly contrary. Bleeding alone will frequently relieve the spasm, but I have known a very simple remedy used with almost general success. Goose fat, in the quantity of a pound or three quarters given warm, generally produces relief in a very short time, if accompanied by walking exercise. In severe cases, one ounce of laudanum and a dram of powdered ginger, in a quart of warm ale, may be used with probable success.

Inflammation of the bowels is worse to cope with than gripes, and a farmer should never attempt the cure himself. He should call in the veterinary surgeon *immediately*. The disease may be distinguished by a coldness of the extremities; this at least indicates inflammation, or that the blood is determined to some local part, and the heaving of the animal's flanks, and his anxious looks at his bowels, as well as their tenderness when touched, will indicate the seat of the inflammatory action. The first object is to relieve the system, and counteract the impetus of the blood; bleeding persevered in until the horse drops, is the only chance for saving his life. There is another principle in horse medicine which here will be called into vigorous action. No severe inflammation can take place in two contiguous parts of the system at the same time. To lessen the internal inflammation, the belly must be largely and powerfully blistered, and these are the two means for subduing the disease. No purgative medicine should be given, but the horse back-raked, to prevent the formation of calculi, and a glyster administered in the form of onion broth.—All stimulants must be avoided, as they are sure to act as poison to the animal. In conclusion, I would impress upon the persons concerned to aim at *prevention*, where their efforts will generally prove available, for they seldom are so in the curative process.

Young Men's Department.

Hints to Young Farmers.—No. XI.

ANALOGY BETWEEN THE CULTURE OF THE SOIL AND THE CULTURE OF THE MIND.

The soil is endowed with the elements of fertility, capable of yielding all necessary sustenance to man. The mind is endowed with all the elements of usefulness and intellectual enjoyment, capable of rendering man virtuous and happy.

The soil, left to itself, brings forth noxious as well as useful plants; and the useful, such as minister most largely to our wants, can only be made to thrive by unremitting care and labor. The mind, left to itself, is the prolific source of evil, as well as of good; and it is indebted for its highest attainments, and most elevated enjoyments, to persevering study and labor.

Culture is the application of labor and skill, to increase and improve the products of the soil, for the gratification of our animal wants. Culture is the application of study and labor, to improve the good qualities of the mind, for the gratification of our intellectual wants. We enjoy the first in common with the brute;—the latter is the prerogative of man.—And both the soil and the mind rise in the scale of usefulness in proportion to the good culture that is bestowed upon them.

Soils differ in their natural fertility; yet those of medium or inferior quality, by the application of labor and skill, are often made to excel, in their products and their profits, those of the first class which are badly managed. Intellects also differ in natural fertility—some develop precocious fruits, while others appear tardy and dull—yet by proper culture and discipline, the latter often, very often, excel, in private virtue and public usefulness. In regard to soils, it has been said, that where nature has been less bountiful, man is most industrious and happy. It may be said of the mind, that where fortune is less prodigal, individual effort is most active and successful in developing its treasures. For,

As rich soils are most prolific in a rank growth of weeds, which choke and destroy the corn, unless timely eradicated—so rich men's sons are very apt to abound in rank weeds of the mind—as indolence and dissipation—which obscure or smother the noblest faculties of the soul, unless sedulously watched and manfully mastered.

The soil requires, in order to obtain a full development of its beneficent powers, not only the *preparatory process* and the good seed, but the *after culture*—that the young plants be carefully nurtured, and that all noxious weeds be extirpated. The mind, in like manner, needs the *after culture*. It is but *prepared* for useful knowledge by the elementary teachings of the school. The good seed is here too to be sown, in the spring time of life, the virtues are to be carefully nurtured, and the bad passions and propensities mastered and controled, if we would gather the harvest of renown, or become useful to ourselves and country.

A well cultivated soil not only benefits, directly, its proprietor, but, by the example it furnishes, and the abundance of its products, it indirectly benefits society at large. So the well cultivated mind not only benefits its possessor, but by its example and its fruits, confers blessings on the whole commonwealth.

The good culture of the soil will supply the means of cultivating the mind. The good culture of the mind will fit it to become a powerful auxiliary to labor, in increasing the products of the soil. The culture of the soil and the culture of the mind are, therefore, of reciprocal benefit to each other.

If you would, as Poor Richard says, be "*healthy, wealthy and wise*," cultivate with diligence—and cultivate well—both your soil and your mind.

Industry vs. Indolence.

J. BUEL, Esq.—Sir—Industry produces a stream that flows slowly on to elevate the inquiring mind, which forms a sure foundation and great barrier against every vice. It is a granary to the mind, where every virtue will be stored: it lends a sweet tincture to every action, which is gratefully cherished.

The man who has no occupation must be quite unhappy; toil is the price of sleep and appetite, of health and enjoyment. How nobly every order is displayed! The very necessity which overcomes our natural sloth is a blessing. Every briar and thorn which is strewed in our path; every noxious plant which the world contains, and every annoying insect which appears to surround us, by divine mercy, could not have been spared.

We are happier with the sterility which we can overcome, by our united exertion, than we could have been by spontaneous plenty, and unbounded profusion.

No way can the body and mind be so morally and effectually improved, as by the toil that fatigues them. That toil receives its manifold rewards daily, by the pleasure it bestows. The enjoyments are so varied and peculiar, that no wealth can purchase them, no honor can win them, no indolence can taste them.

Many people imagine themselves in pleasures, provided they are neither in business nor study. Nothing like it; they leave not one trace of their laborious and intellectual exertion behind them, no more than if they were asleep.

By contracting habits from laziness they frequent only those places where they are free from all those restraints, attractions and demands, which do justly surround them.

This sinks the indolent into contemptible obscurity all the days of his life. He only lives to die in a thousand errors, and rather adopt the prejudices of others than give himself the trouble of acquiring true knowledge, which tends to form correct opinions of his own.

Idleness leaves a man in the lowest state; his pleasures are all sensual, no wants are sought after but those of appetite. The man of industrious habits is looking forward, with a degree of superiority, to more noble and higher attaiments in intellectual enterprise. He dicovers that the happiness of individuals and security of society are formed by the industrious habits which elevate the mind, and is carried forward in search of something more excellent, and obtains a proper degree of superiority over the common senses of life by learning to feel himself capable of higher aims and nobler enjoyments. That which abstracts the thoughts from sensual gratifications, and exerts us to look for happiness within ourselves, will surely advance, in a measure, the dignity of our nature: therefore all good pursuits reward themselves; one truth constantly presents another to view, and while our store of knowledge and enjoyments are constantly increasing, kind nature can never be exhausted.

Industry, properly applied, will most assuredly advance our prosperity: the advantages of which are two-fold; it will, in a measure, be estimated by the pecuniary profit produced, but more by the superior tone of industry and economy which the possessor unconsciously acquires.

That which the industrious has obtained by his own proper and well directed exertion at once causes him to feel raised in the scale of being, and endows him with the capacity of enlarging the stock of his possessions.

When property is accumulated by the industrious peasantry, it never fails to produce impressions on their minds, very lasting and unavoided. In such instances it renders them more industrious. They also strive to better educate their children, that they may be better fitted for some good and useful attainment and station in life.

S. W. JEWETT.

Weybridge, Vt. Aug. 8, 1838.

THE CULTIVATOR:

A MONTHLY PUBLICATION, DEVOTED TO AGRICULTURE.

I KNOW OF NO PURSUIT IN WHICH MORE REAL AND IMPORTANT SERVICES CAN BE RENDERED TO ANY COUNTRY, THAN BY IMPROVING ITS AGRICULTURE.—*Wash.*

VOL. V. NO. 3, WASHINGTON-ST. ALBANY, N. Y. OCTOBER, 1838. No. 8.

Conducted by J. BUEL, of Albany.

TERMS.—ONE DOLLAR per annum, to be paid in advance. Subscriptions to commence with a volume.

Special Agents.—L. & R. HILL, Richmond, Va.; BELL & ENTWISLE, Alexandria, D. C.; GIDEON B. SMITH, Baltimore, Md.; JUDAH DOBSON, bookseller, D. LANDREITH, and M. S. POWELL, seedsmen, Philadelphia; ISRAEL POST, bookseller, 88 Bowery, ALEX. SMITH, seedsman, P. WAKEMAN, office of the American Institute, Broadway, N. York; HOVEY & Co. Merchants' Row, Boston; ALEX. WALSH, Lansingburgh, and WM. THORBURN, Albany, gratuitous agents. For general list of agents see No. 12, vol. iv.

The Cultivator is subject to common newspaper postage.

☞ Price of the published volumes, 50 cents per vol. stitched—the four volumes bound together, $2.75—bound in two volumes, $3—the four vols. bound each separate, $3.25.

THE CULTIVATOR.

TO IMPROVE THE SOIL AND THE MIND.

☞ Farmers' Directory. ☜

☞ We receive almost daily inquiries for seeds, implements, farm stock, &c. many of which it is difficult, and some of them out of our power, to answer satisfactorily. The expense of making and answering these inquiries amounts to no little in the aggregate. To remedy this inconvenience, and to render a service to the seller and buyer, we propose to insert in the extra which will accompany our February number, a FARMERS' DIRECTORY, that is, to give the names, residence and business, so far as they shall be notified to us by the 10th January, free of charge, of gentlemen engaged in vending agricultural seeds, implements, and choice breeds of farm stock, in whatever state they may reside. As for example,

W. Thorburn, Albany, vends seeds and implements.

H. D. Grove, Buskirk's Bridge, Washington co. N. Y. will sell 100 Saxony sheep.

G. B. Smith, Baltimore, Md. sells Rohan Potatoes and Dutton seed corn.

To the patrons of the Cultivator, no charge will be made for this notice—to others, it will be one dollar. Advertisements, more in detail, will be inserted in a separate portion of the same sheet, on our usual terms. The advantages that are likely to result to advertisers, may be judged from the fact, that our edition is twenty thousand copies, and that our paper circulates in every state and territory in the Union, and in the Canadas.

The Farmer's Garden.

FRUIT.

The fruit *trees* that may be cultivated in a garden, where the climate and soil will admit of their growth, are the apple, pear, plum, cherry, peach, nectarine and apricot; the fruit *shrubs*, are the quince, gooseberry, currant, raspberry; to which we may add the grape and the strawberry.

Each of these fruits may be profitably cultivated for market, where a market is contiguous or convenient; and they may all be made subservient to the economical subsistence of the owner's family, to a certain extent,—and certainly furnish some of the most grateful, and at the same time healthful delicacies and luxuries of the table. Hence the extent of their culture may be made to depend upon the demand.

It will be seen in the plan of a garden presented in our last, that nearly one-half, or half an acre, is appropriated to fruit *trees* and grape *vines*. Plats Nos. 8 and 9, will contain each 15 trees, at 12 feet apart, with intervals of five feet between the outside trees and the walks, and a trellis of grape vines along the southern borders of both plats. Numbers 10 and 11 will each receive 20 trees, at nearly similar distances. Thus the fruit department may contain 70 trees, and 20 grape vines, without materially interfering with the vegetable or ornamental departments.

The next question is, with what fruits shall these plats be planted? This depends upon another question—what fruits will thrive and mature in the soil and climate? The apple will admit of general culture; for although Coxe has fixed the northern border of the apple zone in the valley of the Mohawk, this fruit is nevertheless found in high perfection as far as lat. 45°, and even on the island of Montreal. And the defects of soil, it is believed, may in most cases be corrected, by underdraining and trenching. The plum, pear and cherry, do not do well in high northern latitudes, though they are grown to some extent on the borders of the lakes, upon our northern frontier. The peach is not successfully cultivated north of 42° upon tide-water, until we get west into the valley of the Seneca river, and within the influence of the predominating south winds, which come from the Gulph of Mexico. These winds are believed to be the trade-winds of the tropics, turned out of their western course by the high table lands of Mexico; and their mild influence is felt, more or less, as far north as the island of Montreal. The nectarine and apricot, so far as our observation has gone, seldom repay the expense of culture north of the city of New-York, unless protected by glass. The grape, even the hardier varieties, seldom ripens well north of 43°, and the fruit of the foreign varieties is very subject to be destroyed by mildew, or to lack fine flavor, unless secured in a house.

But supposing all the fruits we have named may be cultivated, we would appropriate the northern row in plats 8 and 9, to early apples, suitable for the kitchen and dessert; and instead of ten we would plant but six trees, which would give intervals between the trees of about 20 feet. As the apple is the largest growing tree, we would plant it on the north, as its shade, in that position, will be least prejudicial to other garden crops. The fruit never comes amiss in the family; if there is any excess, it is readily converted into pork; and if early apples are grown in the garden enclosure, they are most safe from depredations, and more convenient when wanted.

The next, in the size of fruit trees, are the cherry and the pear, and these may be made to occupy the other two rows in the plats under consideration; and as these should have intervals of at least 15 feet, the space will admit of but 16 instead of 20 trees. Should grapes not be made to occupy the place assigned them in these plats, the intervals, north and south, may be extended to 15 feet; or the spare strip may be profitably appropriated to nursery rows, to supply trees and shrubs to replace those which may fail or die, for the propagation of new varieties, and as a school of instruction in budding and grafting.

Plats 10 and 11, may be appropriated to the smaller growing trees, as plum, peach, &c. and will each contain 20; or the nursery may occupy a part of this ground. The rows of the nursery should be three feet asunder, and the plants one foot apart.

Many persons, to avoid the trivial expense demanded for good fruit, content themselves with seedlings, or inferior kinds, which they can obtain without price. This is bad policy. Good fruit is pleasant, healthy and profitable. Bad fruit has neither of these properties to recommend it. We have seen a cherry tree whose fruit had brought its owner fifty dollars; a pear tree which yielded its proprietor twenty dollars every bearing year; and plums which have readily commanded five dollars a bushel in the market. And we have seen other trees that virtually brought no profit to their owners, or food to the family, for the reason, that the fruit they produced was actually worth nothing. The catalogue of the London Horticultural Society, contains the names of more than 1,400 varieties of the apple, 700 of the pear, and nearly a like number of the peach, plum, &c. These fruits are arranged in three classes, according to quality: No. 1 being very good; No. 2 so so; and No. 3 comparatively worthless. Probably not more than one-tenth of these fruits belong to the first class.—We mention this fact to show, that superior fruits bear but a small proportion to the inferior kinds which are cultivated. An outlay of a few shillings in the purchase of good fruit in the outset, will, when the trees come into bearing, annually and amply compensate for the expense; and when once obtained, good fruits may be as easily propagated in the garden nursery as bad fruits. Young men, of ordinary capacity, *can* acquire the art of propagating, if they will but try, after a little practice.

The quince, the currant, the gooseberry and the raspberry, may occupy the east and part of the south border. The first should be planted 8, and the others 4 feet asunder. The strawberry may be grown in the southern edge of the fruit plats, or be assigned a place in the outer borders.

In recommending varieties of fruit for garden culture, we shall name such as we *know* to be good, without meaning to say that other varieties are not equally so. Every district of country has some kinds peculiar to itself. Besides, a list of all the good fruits would swell our article to a tedious and useless length. We therefore content ourselves with naming but a few varieties of each. But we remark, that new varieties are every year produced by the natural process of crossing. On a late visit to our friend I. Denniston, Esq. who perhaps has the best collection of plums of any man in America, he gave us to taste some fifteen new seedling varieties of this fruit, all of exquisite flavor.

EARLY APPLES.

Juneating, tart bough or harvest apple, strawberry apple, sapson, early French reinette, pumpkin sweeting, fall pippin, and for baking, the sweet bough, or Jersey sweeting. The apple should be raised from seed, and choice kinds may be multiplied in the garden nursery, by grafting or budding. Graft in April, and bud in July and August. Bud when the plants are the size of the little finger. For directions see the Cultivator, vol. II. p. 18, 65, 66.

PEARS.

We name those that ripen at different times, and in the order in which they ripen: Jargonelle and Williams' bonchretian for summer; autumn, or Gansell's bergamot, vergaleu, capiaumont, seckle, &c. for autumn; beurre diel, chaumontelle, colmar, easter beurre, &c. for winter; catillac or bell, for baking. The pear may be propagated and worked like the apple. If dwarf trees are desired, they may be worked upon stocks of the quince or thorn, at the surface of the ground.

CHERRIES.

We would have among these the morello, mayduke, black heart, white heart and late duke—the common red cherry should also have a place here, or in some other part of the premises. The cherry is generally budded, and this should be done in June, or while the plants are in thrifty growth.

PLUMS.

The green, purple, yellow, Bleecker's, Flushing and blue gages, are all excellent, as are the Bolmar, Nectarine, Orleans, St. Catharines, Jefferson, and many others. The egg and magnum bonum, belong to the second class as to flavor, though they are of the first class in size. Plums are propagated by budding and grafting; often upon succors which grow from the roots of old trees, though better stocks are readily obtained from seeds. The plum should be budded in June, or early in July—grafted in April.

PEACHES.

These are generally short-lived trees, and where they can be raised and fruited well, a supply of young trees should be constantly kept up in the nursery.—The peach should always be budded, as not one seedling in fifty turns out good fruit. The stones may be buried in the ground during winter, and those that are not cracked by the frost should be broken before they are planted. They may be sown thick, like cabbages, in a seed bed, and like cabbages transplanted into nursery rows with a dibble, when they have grown six inches high. They *may* be budded early in September, the same year, and *should* be budded as early as the second year. There is no fruit more easy of propagation, or that comes earlier into bearing, than the peach; and where it thrives well, there is no apology for neglecting its culture, or for not propagating the choice varieties; and nearly all that are worked in nurseries are of this description.

QUINCES

May be propagated by layers, by cuttings, or by seeds. Seeds may be sown like apples and pears, and transplanted when of sufficient size, in two or three years. The apple shaped, the pear shaped, and the Portugal quinces, are the principal varieties, of which the latter is generally preferred. It is of a fine purple colour when dressed, and is more juicy and less harsh than the other kinds.

GRAPES.

The Isabella, Catawba and Bland's Virginia, are the most esteemed native varieties; and the Sweetwater, Chasselas and black Hamburgh, the best foreign varieties, for culture in the open ground. The grape is propagated by layers and cuttings. For the management of the vines, see the directions of Alden Spooner, in the May number of the current volume. It is considered prudent in the climate of Albany, to lay grape vines, in autumn, upon the ground, even of the Isabella, and slightly to cover them with earth, after being previously pruned.

CURRANTS

Are a valuable fruit in family economy, are a long time in use, and are a marketable crop. New plantations of this fruit should be made every ten or a dozen years, as old wood becomes diseased, the ground upon which it grows exhausted, and the fruit upon it inferior. The varieties are the black, common red and white, the Dutch, or large, or grape, white and red, champaign, &c. The Dutch are the best. They do not produce so much wood as the common; but they give proportionally more and larger fruit, particularly the red.

GOOSEBERRIES

Are liable to be spoiled by mildew; but we have reason to believe, from the experiments we have made, that the disease may be prevented by a strong pickle being poured about the plants in winter, when vegetation is dormant. The varieties of this fruit are very numerous. The thin skinned of medium size are the best.

For directions for propagating the gooseberry, currant and grape, by layers and cuttings, see pages 29 and 30 of vol. III. of Cultivator.

RASPBERRIES,

Particularly the white and red Antwerp, are deserving of culture, where this fruit does not abound in a wild state. They are propagated by succors, that is, shoots which come from the roots of old plants. The canes, or stems, of the Antwerp raspberry, bear but one season, and are succeeded annually by a new growth. We cut away the dead wood in autumn, reduce the canes to four or five in a place, cut in the laterals, and also the top to the height of about four feet, and as a precaution against the frost of winter, bend down two stools towards each other, secure them at the surface of the ground by a crotched stake, and slightly cover them with earth. The raspberry requires a new berth once in four or five years, to bear well.

STRAWBERRIES.

We treated of this fruit so fully in our August number, as to supersede the necessity of adding any thing more at this time.

TRANSPLANTING.

We will only state, briefly, that in transplanting, care should be taken to give the roots their natural direction—to surround them above, below, and at the sides, with rich surface mould—and to bring this mould every where in close contact with them. As to the SEASON of planting, we should prefer early autumn, as soon as the functions of the leaves are destroyed by frost, and while there is yet a sufficient flow of elaborated sap, to produce new fibrous roots—or late in the spring, before the leaf buds have burst, and when there is a brisk circulation of ascending sap. "If trees have been planted in autumn," says Reynolds, in his Guide to the Orchard and Kitchen Garden, "they will, by the following April, have made fresh roots, and their buds will begin to push." If transplanted in autumn, it is well to throw around the plant two or three forks' full of mulch or coarse dung, to protect the roots from severe cold; and the like precaution will prevent excess of evaporation in summer.

Having thus disposed of the fruit department, we shall, in our next, treat of the culinary department of the garden.

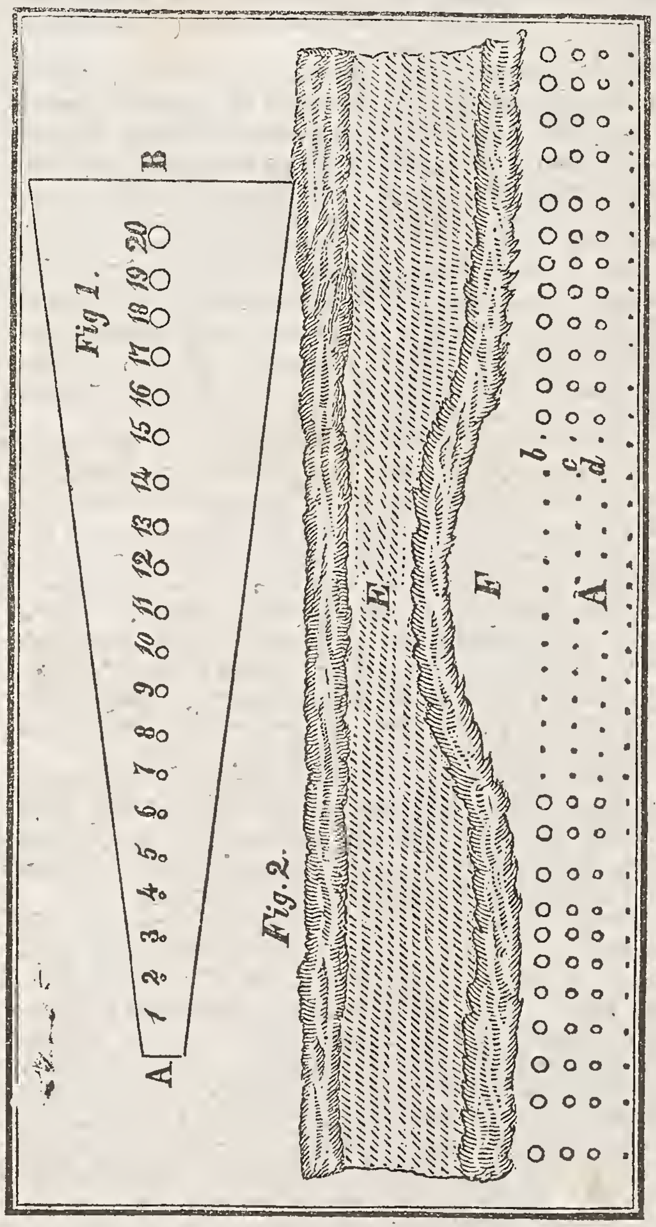
Office and Extent of the Roots of Plants.

Roots perform a double office to plants: they serve as braces to keep them in an upright position; and they are purveyors to supply them with food suitable to their growth and maturity. To enable them to perform these offices well, three requisites in the soil are essential. *First.* It is important that the soil be mellow, that the roots may penetrate in it freely, not only to strengthen their bracing properties, but to extend their range for food, this being absorbed or taken up by the spongeoles, or extreme points—and the greater their range the more abundant the food which they supply. *Secondly.* It is important that this food be in the soil, in a soluble state, that is, in a condition to be dissolved by, and incorporated with, the fluids in the soil. This food consists of vegetable and animal matters,—or of whatever has been such. *Thirdly.* It is important that a quantity of moisture be always present in the soil, to dissolve the food of plants, and to serve as the medium for conveying it first to the spongeoles, and from thence into and through the plant. Air, heat and moisture, are all essential agents in preparing the food of plants, in the soil, and in giving vigor to vegetable growth.

It should be the object of the farmer and gardener to aid these natural operations in cultivated crops; and to repay the soil, by labor and skill, for the annual tribute which they draw from it. These labors consist in returning to it vegetable food—dung—equivalent to that which they annually take from it,—in rendering it mellow and permeable to the roots of the growing crop—in regulating the supply of water, for too much is as hurtful as too little—and in keeping the surface loose and porous, for the free admission of air, heat and moisture. Hence the advantage of deep tillage, perfect pulverization, of draining, manuring, and the frequent use of the cultivator among drilled or hoed crops; and these considerations also suggest one objection against using the plough in the after culture of these crops, and of earthing or hilling them to any considerable extent—as both of these modes of culture, ploughing and hilling, tend to curtail the natural range of the roots, and consequently to diminish the pasture and food of the crop.

The depth and horizontal spread of roots, is greater than is generally apprehended, and they often branch into minute filaments imperceptible to the naked eye—and yet these minute imperceptible filaments collect food for the parent plant. Jethro Tull, the father of drill husbandry, has given us a good and satisfactory illustration of the great extension of the roots of the common turnip, which we transfer to our columns, not only to convince our readers of the fact, but to illustrate the importance of good ploughing and thorough pulverization in tillage husbandry. We invite attention to the cut, and then to the explanation in the words of Tull.

[Fig. No. 50.]



"*A method to find the distance to which roots extend horizontally:* A piece, or plat, dug and made fine, in *whole hard ground,* (Fig. 1,) the end A two feet, the end B twelve feet, the length of the piece 20 yards; the figures in the middle of it are 20 turnips, sown early and well hoed. The manner of this hoeing must be, at first, near the plants, with a spade, and each time afterwards a foot distance, till the earth be once well dug; and, if weeds appear where it has been so dug, hoe them out shallow with the hand hoe. But dig all the piece next the out-lines deep every time, that it may be the finer for the roots to enter, when they are permitted to come thither. If the turnips be all bigger as they stand nearer to the end B, it is a proof that they all extend to the outside of the piece, and the turnip 20 will appear to draw nourishment from six feet distance from its centre. But if the turnips 16, 17, 18, 19 and 20, acquire no greater bulk than the turnip 15, it will be clear that their *roots* extend no further than those of the turnip 15 does; which is but about 4 feet. By this method, the extent of the *roots* of any plant may be discovered. There is another way to find the length of *roots,* by making a long narrow trench, at the distance you expect they will extend to, and fill it with salt; if the plant be killed by the salt it is certain that some of its roots enter it.

"What put me upon trying this method, was an observation of two lands or ridges (fig. No. 2,) drilled with turnips in rows, a foot asunder, and very even in them; the ground at both ends and one side, was hard and unploughed. The turnips not being hoed, were very poor, small and yellow, except the three outside rows, *b, c, d,* which stood next to the land (or ridge) E, which land, being ploughed and harrowed at the time the land A ought to have been hoed, gave a dark flourishing colour to these three rows; and the turnips in the row *d,* which stood farthest off from the new ploughed land E, received so much benefit from it, as to grow twice as big as any of the more distant rows. The row *c* being a foot nearer to the new ploughed land, became twice as large as those in *d;* but the row *b,* which was next to the land E, grew much larger yet. F, is a piece of hard whole ground, of about two perches in length, and about two or three feet broad, lying betwixt those two lands, which had not been ploughed that year. It was remarkable, that during the length of this interjacent hard ground, the rows *d, c, b,* were as small and yellow as any in the land. The turnips in the row *d,* about three feet from the land E, receiving a double increase, proves that they had as much nourishment from the land E as from the land A, wherein they stood, which nourishment was brought by less than half the number of *roots* of these turnips. In their own land they must have extended a yard all round, else they could not have reached the land E, wherein it is probable that these few roots went more than another yard, to give each turnip as much increase as all the roots had done in their own land. Except that it will hereafter appear, that the new nourishment taken at the extremities of the roots in the land E, might enable the plants to send out more roots in their own land, and receive something more from thence. The row *c* being twice as big as the row *d,* must be supposed to extract twice as far; and the row *b,* four times as far, in proportion as it was of a bulk quadruple to the row *d.*"

"When roots are in a tilled state," says Tull, "a great pressure is made against them by the earth, which constantly subsides, and presses their food closer and closer, even into their mouths, until itself becomes so hard and close that the weak sorts of roots can penetrate no farther into it, unless reopened by new tillage."

Tull's work was published a hundred years ago.—It has been quoted and commented upon by most of the subsequent writers upon agriculture; and the facts above stated have neither been controverted nor disputed, either by these writers, nor, so far as we have learnt, by practical farmers. They are therefore undisputed. Why is it, that cultivated crops, upon the margins of fields, and about stumps and fast stones, give more dwarfish plants, and less product, than the well-tilled portions of the field? It is not owing to the poverty of the soil; for these portions abound most in the elements of fertility, by reason of the plough, on being raised from the furrow, depositing there the finest and richest mould. Why do meadows deteriorate? Is it not because the roots of plants have not a sufficient range, in mellow earth, to supply the requisite food—and because the unbroken soil "becomes so hard and close, that the weak sort of roots can penetrate no farther upon it"?

There are some practical improvements which we would draw from the preceding facts. And—

First—in regard to the use of the plough in Indian corn, and other hoed crops. The roots of Indian corn are known, from repeated observation, to extend in the soil at least six, eight and ten feet, and if planted in squares four feet apart, each hill has virtually a pasture of four feet square to feed upon. Now if the plough is run both ways through the crop, this pasture is reduced to at least two square feet, for the roots which furnish sustenance are within reach of the plough, and must be cut by it. Hence the plough reduces the pasture of each hill, while it continues to be employed, from sixteen to four square feet, or three-fourths.

Secondly—in regard to the application of manure, whether it should be applied in hills and drills, or spread broadcast. The roots extend simultaneously with the stems, and draw sustenance for the plant through their extreme points. Hence, by the time the crop is first dressed, the roots have extended beyond the manure deposited in the hill, and consequently the plant derives but a partial benefit from this central deposite of food. If, on the other hand, the manure is spread broadcast, the roots, as they extend, are constantly reaching new supplies, and the plant is sustained in undiminished vigor.

Thirdly—in regard to fallow crops, instead of naked fallows. Where sward ground receives but one ploughing—but that should be a thorough one—the vegetable matter of the surface is turned completely under, safe from the wasting influences of the weather. This vegetable matter readily decomposes, furnishes a permeable stratum for the roots, the food which these roots seek for, and moisture to convey it to the plants which require it. As the roots of the sod decay, the upper stratum becomes permeable to heat and air, and crumbles into a fine tilth. In the case of naked fallows, a good portion of the vegetable matter is lost, by being turned to the surface at the second ploughing, and the ground consequently becomes more compact, and is not so readily penetrated by the roots of the crop, nor by heat, air and moisture, the essential agents of vegetable growth. And

Fourthly. The facts which we have detailed, afford a strong argument in favor of the alternating system of husbandry, wherever it can be introduced—of periodically breaking and pulverizing the soil, with the plough, harrow, roller and root crops, thereby rendering it more congenial to the growth of grasses and small grain.

Varieties of Grain.

Le Couteur, in his excellent publication on wheat, which we propose to notice hereafter more fully, states that his collection consisted of 150 varieties, or kinds. The varieties of wheat, like those of the apple, may be multiplied without number, by sowing different kinds contiguous to each other—the pollen of one kind impregnating the pistil of another, and the two, thus conjoined, produce, like two animals of different breeds, a new variety, partaking, more or less, of the qualities of the two parents. This change is not so perceptible in the seed of wheat as it is in the seed of Indian corn; but it is, nevertheless, as certain, in the habits of the new plant. We have particularly noticed this tendency to amalgamate in the maize crop, where it becomes palpable to the eye in the new corn. We planted, last spring, seven kinds of maize, a couple of rows of each, in the same field, at intervals of some 20 to 30 feet, with a view of determining both their comparative earliness and productiveness.—Every variety has become impregnated with two or more other kinds, as is indicated by the colour of the grain—and though, from the colour, &c. of these strange grains, they appear to be identical with the male parent, they will, if preserved and planted, produce entire distinct varieties. Upon the mode of producing new kinds of maize artifically, see the interesting articles from A. Robinson and G. B. Smith, in our April and May numbers.

We make these remarks preliminary to the notice of a fact, stated by M. Le Couteur, of much interest to the farmer, viz. that all our old varieties of wheat have become very much mixed, if not adulterated, by the natural process of crossing. M. L. says, that in 1832, he thought his crops were tolerably pure, yet on Prof. La Gasca, curator of the royal garden at Madrid, walking through them, he selected 23 sorts, of which some have since been discovered to be three weeks later in ripening than others. "Hence," says M. L. "I repeat, it must be obvious, that corn harvested in an unequal state of ripeness, cannot be the best for making bread,—when the greater part of the grain has been reaped in the state the farmer considered was fitted for the miller, whilst the lesser part has been in a milky state, or much over ripe, or some in states between both." To this cause he ascribes the appearance of many shrivelled, lean and ill grown grains, in many samples of wheat. We paused, while penning this article, Aug. 28, to examine several kinds of wheat, which we have growing in an experimental plat; and we found M. L's remark verified, more or less, in all, but least in the Trimestrian. In the Italian, Siberian, Tea, Egyptian, Galena and Chilian, some heads were over-ripe, some were in condition for harvesting, and others were quite green. These wheats were all sown May 19, and may be put down as to their forwardness, in the following order: earliest, Italian, Tea, Siberian, Galena, Egyptian, Chillian, Trimestrian. There are some ripe heads upon all, and some green heads upon all. Of their relative productiveness, we shall speak hereafter. It should, however, be remarked, that the seeds of these wheats come from various climates and latitudes, which undoubtedly has influence upon their maturity.

The above facts suggest the propriety of using great care in the selection of seed—that the kernels appear of equal maturity—that the seed has not been grown contiguous to other varieties—and of beginning, *de novo*, as the Scotch farmers have done in various instances with wheat, oats, barley, &c. by selecting a plant, or stool, or an ear of choice grain, and of propagating it carefully, till the product will suffice for an entire crop. The intrinsic value of the product would, in a very few years, amply compensate for the trouble. It was in this way that the Houpton oat, chevalier barley, and various other highly esteemed varieties of grain, now eagerly sought for, first obtained notice.

There is one other observation of M. Le Couteur, that we found amply verified in our early practice in farming—the impropriety of applying fresh stable dung to land intended for wheat, and, indeed, in our opinion, to land intended for any small grain, "inasmuch as it tends to produce much grass or straw, and less grain, which grain is also of a dark coarse nature. *Stable dung should be applied plentifully to the preparatory crop*," and lime or ashes to the wheat when they are procurable.

M. Le Couteur quotes Columella's account of the varieties of wheat cultivated in his time, which was about the commencement of the Christian era.—Among the varieties described by Columella, we observe one whose name and character materially correspond with a sample sent us by Mr. Ashburner, of Stockbridge, last spring, and which we have grown. We subjoin the quotation.

> "The Trimestrian," says Columella, "shall be the third, which husbandmen are mighty glad to make use of; for when, by reason of great rains, or any other cause, the early sowing has been omitted, they have recourse to this for their relief. It is a kind of white wheat. Pliny says, that this is the most delicious and daintiest of any sort of wheat, exceeding white, but without much substance or strength, only proper for moist tracts of land, such as those of Italy and some parts of Gaul; that it ripens equally, and that there is no sort of corn that suffers delay less, because it is so tender that such ears of it as are ripe presently shed their grains; but in the stalk, it is in less danger than any other corn, for it holds its ear always upright, and does not contain the dews, which occasion blasting and mildew."

The Diseases of the Plum and Pear,

That is, the canker on the one, and the blight on the other, continue to arrest the attention and employ the pens of our horticulturists and pomologists. The causes that are conjectured, and the cures that are recommended, are almost as multiplied as the writers. There is no doubt in our minds, that many of the failures in these fruit trees, are owing to a bad soil, or bad subsoil—to the absence of some matter essential, or to the presence of something prejudicial, in the soil, to their health and vigor. But the diseases in question, which, so far as our memory serves, are comparatively recent, are undoubtedly caused by insects. "Like causes produce like effects," is a maxim of unquestionable truth. The elements remain as they always were. If these diseases were owing to the soil, the sun or the atmosphere, why were they not known to our grandfathers? But that new insects are continually coming among us, is wofully evidenced by the depredations of the Hessian fly, the bee moth, and the grain worm, which depredate upon our wheat and our honey. And why not the like new and unwelcome visitors upon our fruit trees? Another reason for imputing these diseases to insects is, that they seem to come periodically—to intermit for years—and to continue for years. We saw the pear blight in 1801, and in 1825; and the canker in the plum at different periods. For the last few years we have been comparatively exempt from both. Insects do appear at intervals of years. The locust is said to be fourteen or seventeen years in its various transmutations. We yet know hardly half of the insect creation. All matter seems animated with life, which, in its minutest form, is capable of inflicting incalculable injury upon man. See, for instance, the aphides, which prey upon almost every plant; the fly and grain worm which destroys our wheat—the various tribes which live upon our farm-stock, and others that are parasites upon man. And are fruit trees alone, of all animated nature, to be exempt from these minute enemies, which cause disease and death?

Diseases of trees, we have said, are often to be ascribed to the absence, in the soil, of something essential to the plant, or of something prejudicial to its growth. Where this is the case, the evil, we think, may in most cases be remedied, by trenching the ground, preparatory to planting, and by the admixture of clay, or lime, or such other elementary matter as the soil may appear to be deficient in. Last autumn, we followed Mr. Reed's suggestion, and placed around many of our pear trees furnace cinders; and around others tan from the morocco factory.—The earth was taken away from around the base of the trees, two or three shovels full of the material thrown in, and the earth thrown back upon it. No blight has appeared upon them, and most of the trees have started with new vigor. Whether the cinders and the tan benefit, by neutralizing something obnoxious in the soil, or by affording a requisite food, we are unable to say; but it seems certain that they promote health and growth.

Varieties of Early Indian Corn.

The *Maine Farmer*, of Aug. 21, says, "the Dutton corn grows luxuriantly, but is much later than many of the old varieties."

The *Farmer and Gardner*, of the same date, printed at Baltimore, states two cases of the Dutton corn being gathered, in a ripe state, in less than 90 days from the time of its being planted, viz. Mr. Giles planted on the 17th May, and gathered perfectly ripe samples on the 15th August; and Mr. Harrison planted, on the 16th May, and gathered on the 14th August.

The *Franklin Farmer*, printed at Frankfort, Ky. of Aug. 18, says, "Our Dutton corn, planted April 30, has been gathered more than a week. It is perfectly ripe, hard and well cured. Though a dwarf species, it is a generous bearer, and we are satisfied, from the experiment of this season, that an acre of it will produce as good an average crop as our larger eared corn."

Some of our Dutton corn, planted on the 19th May, had perfectly ripe ears on the 15th Aug. and this part of our crop was harvested, that is, cut up, on the 28th Aug. though it might safely have been done on the 21st; and most of the Dutton corn in our neighborhood, was harvested either in August or the first week in September.

We have recorded these facts, to explain their seeming contradictions, and to make some suggestions, which we think of importance to the farmer, in regard to seed.

We have before observed, that there is a spurious, as well as a genuine, Dutton corn, the former of stouter growth, and later in ripening, than the latter. We would remark, that this difference may result from the seed planted—seed of the same variety, grown at the south, giving a larger growth of stalk, and maturing later than seed grown at the north.—This is evidenced by the fact, that southern seed always gives a comparatively large and late growth at the north; while northern seed gives a dwarfish growth and early maturity at the south—and that they both become acclimated in a few years, and take the habits of their new location. These considerations suggest, that so far as early maturity is sought for, it is advisable, when a change of seed is desired, to obtain it from a more northern latitude, or elevated district.

But we adopt the opinion of Joseph Cooper, so far at least as relates to maize—which was, that a change of seed is *not necessary*, when due regard is paid to *selecting* the seed. We have cultivated the Dutton variety of corn eighteen years—we have always selected the earliest and fairest ears, assisting in person, for seed, which we immediately braided, and hung in an airy loft. It has ripened as early this, as it did the first year we received the seed from the far north; while we are satisfied it has increased in productiveness—that it has larger ears, and more of them, and taller stalks, than it had when we first began its culture. The seed is left to mature on the stalk, till the crop is gathered from the field—the earliest ripened, being then easily determined by the appearance of the shuck, or husk, and the rich colour of the corn. Hence the importance of every farmer taking care to secure, in person, his best seed.

There is one other fact that should not be lost sight of—the influence of soil and location upon vegetable growth. A moist, rich soil, will give the largest growth, both of foliage and fruit, and a light and dry one the earliest maturity, and the richest or most concentrated product. Prof. Ives states, that plants from the seed of the morus multicaulis, have the foliage of the parent in a rich humid soil, while they resemble those of the M. alba, on a thin light soil; and it is believed that a pound of the leaves of the latter are intrinsically more valuable to the silk-worm than a pound of the former. It is not the size that indicates superiority in the animal or vegetable. A very large apple is seldom a very good one. The cider from a hilly, dry, calcareous soil, is always superior to that from a low and rich one. A very large beet contains much less sugar than the same weight of small beets. Indian corn, grown upon a light dry soil, comes to earlier maturity, but is inferior in its growth, and in the size of its ears, than when it is grown upon a highly manured loam. Indeed the difference is so great, on our own grounds, this season, that the growth and product in two locations, would hardly be taken for the same variety.

We have another suggestion to make, in regard to the influence of steeps. It will be remembered, that in our last volume, we referred to a communication of Senator Johnson, inserted in the first volume of the transactions of the old agricultural society, showing that the crop from seed wheat, steeped in a solution of salt-petre, ripened two weeks earlier, and gave 25 per cent more product, than the crop from seed which was not thus steeped. We began to plant our main crop of corn on the 12th May, and finished on the 16th. All the seed was steeped 12 hours in a solution of nitre, in quantities sufficient for one day's planting. A few quarts of seed, which remained, was set in the cellar, where it remained, partially covered with pickle, till the 19th, when it was planted in a vacant patch of thin soil, in which we also planted, the same day, six other varieties, all reputed to be remarkably early, and the seed of all which had been soaked in salt-petre water. The last planted Dutton corn, was decidedly the earliest of the seven sorts in coming to maturity, and was at least two weeks earlier than the main crop, planted from three to six days earlier. Its maturity may have been in some measure accelerated by the porosity of the soil, compared with that of the main field, which was highly manured with unfermented dung, and to the consequent influence of the dry weather; yet we think it not improbable that it was principally owing to the seed having remained saturated, for 96 hours, in the nitrous solution.

Having referred to our specimen plat, we will add, that it consists of the following varieties of corn:

1. Dutton; 2 and 3. Lake Superior and Squaw from Lake Michigan; 4. Early white, not recollected where from; 5. Early Canada, from Poughkeepsie; 6. Red Blaze, from Elmira; 7. Early yellow, from Vermont. These varieties were all planted the same day, two rows of each, with intervals between the different kinds of 20 or 30 feet. On examining them to day, Aug. 28, we find No. 1 mostly ripe, the husks dry and separating from the grain; No. 2, Lake Superior, an 8 rowed yellow, growing 4½ feet high, but very prolific in succors and ears, next to the Dutton in maturity. The early white is an 8 rowed corn, 5½ feet high, and is third in ripeness. The Vermont is a yellow 8 rowed corn, grows 6 feet high, and is next in ripeness to the early white. The Squaw, No. 3, is an 8 rowed coloured grain, grows 6 feet high, and is fifth in its earliness. The Red Blaze comes

next, and the early Canada is the latest. Both are eight rowed, and, like the Dutton, they grow seven and eight feet high. As to *number* of ears on a stock, they are about alike, except the Lake Superior, which is far the most prolific in its succors and ears, though they are very small. As to the *size* of ears, the Dutton has a manifest superiority; as to length of ears, the early Canada and the Red Blaze, 8 rowed, are equal, if not a little superior to the Dutton. Several gentlemen, who have visited the plat, concur in the correctness of this statement. We intend to exhibit samples of each of these varieties, at the fair of the American Institute. We omit the notice of later ripening varieties.

The Crops.

In addition to the notices of the crops, which will be found under correspondence, we give the following brief abstract from the newspapers:

In Maine, the crops are generally good. The grain-worm has, however, done considerable damage to wheat.

In New-Hampshire and Vermont, the early harvest was abundant, and the Indian corn has been much better than ordinary.

In Massachusetts, the crops have been better than ordinary, though the potato and other late autumn crops, have suffered in the southern parts of the state, as they have through all the middle states, from the drought in July.

In Connecticut, the injury from the dry weather in July, has greatly diminished the autumn crops. though the early ones are believed to have been good.

In New-York, the summer harvest was generally abundant, and well got in. South of Albany the dry weather has seriously diminished the product of the latter harvest, particularly of the potato crop. North of Saratoga, no want of rain has been experienced, and the autumn crops are fine. The same remark, we believe, will apply to Oneida, Onondaga, and most of the counties lying in the more elevated portions of our state. In the western counties, the drought of July did considerable damage, and still more in the southern counties.

In New-Jersey, it will be seen by the letters of our correspondents, in this and our last numbers, the autumn crop has, in a measure, been a failure.

In Pennsylvania, Maryland and Virginia, the wheat crop was good, the rye inferior, oats a small yield, corn very deficient, and potatoes a virtual failure.—The Commercial List, of Philadelphia, states as follows, in regard to East Pennsylvania and New-Jersey: Wheat, decidedly good. Rye, half an average crop. Oats, two-thirds of an average. Corn, one-fifteenth of an ordinary crop. Buckwheat, little expected. Potatoes, early kinds very light; late, an entire failure. Hay, first crop good. Pasture, none in August.

In Delaware, the corn crop promises to be an average one.

In Maryland and Virginia, the wheat has been good; but the corn has been seriously injured, and in many cases utterly destroyed, by the dry weather.

In the states still more south and west, the wheat crop has been great, and the corn generally promised at least a medium crop.

We shall go more into detail in these matters in our annual report. In the mean time, from all the information in our possession, we venture it as our opinion, that wheat is much more abundant, and that flour will consequently be lower in market, this winter, than it was last; that Indian corn, and probably rye and oats, will sustain their present prices, and may advance; and that potatoes will command, south of our latitude, an unusually high price. The failure of the potato crop, and, we are sorry to add, the unusual depredations of the fly upon the ruta baga, will undoubtedly have an influence upon the price of the coarser grains and hay, which latter, however, may be considered abundant throughout the union.

Will the politician, the manufacturer, the merchant and the mechanic, pause a moment, and reflect upon the controlling influence which the abundance or scantiness of the harvest has upon the prosperity of our common country, and upon their several pursuits? If the harvest is abundant, the whole land is prosperous and happy. If the harvest fails, every class feels the electric shock, business becomes stagnant, embarrassments multiply—and the whole land mourns. How important is it then, that all should feel and exert a direct influence in encouraging and qualifying the husbandman to increase the products of the soil—by legislative patronage, and by a system of enlightened education, calculated at once to make better farmers and better citizens.

Pruning of Trees.

If there is any branch of rural economy, which a over and cultivator of good fruit should personally nderstand better than another, it is that of pruning nd taking care of his fruit trees. As but very few understand *how* and *when* the operation of pruning is best performed, it is extremely difficult to *hire* it done well unless the owner himself is competent to direct in the matter.

In all sorts of trees reared for standards, the first object is to obtain a straight bole or stem, at least to a given height, sufficiently stout and tapering to sustain the top. Having acquired the requisite height, the next object, in the management of fruit trees, is to obtain a proper and productive top. To effect the first point, the common practice is, to begin to prune at the *bottom*, and to divest the lower part of the plant of its limbs and leaves. The consequence is, that the plant becomes spindling—the growth being perfectly equal up to the first branches—top-heavy, and ultimately ill-shaped; or, being deprived of a great portion of its leaves—its lungs or elaborating organs,—its growth is materially checked. Those equally err who do not prune at all; as the branches soon interfere with each other, the top becomes too thick to produce or mature well its fruit, and the consequence is a *growing*, not a bearing tree.

In the first stages of growth, the object being to get height and strength, few or no branches should be cut close to the bole, and the long ones, and those that compete with the leading shoot, may be shortened one-half their length; but not a healthy leaf should be unnecessarily removed from any part of the plant. Thus the stem will grow tall and strong, with a gradual taper from the lower branch to the terminal point at top. As to the time of pruning, particularly the apple, we persist in recommending—the long days in June,—when the plant is full of elaborated sap, and yet the flow of sap so moderate, as to be taken up by the remaining branches, without generating succors.

Fumigation to Destroy the Grain-Worm, &c.

We are told that fumigation has been resorted to, to prevent the depredations of the grain-worm; and that although attended with some labor and expense, it has been found to be both successful and economical.
